The mastic tree, which is also called *lentisk* or *lentiscus,* is a shrub or small tree, seldom more than twelve feet in height, much branched towards the top, and furnished with petiolate, abruptly pinnate leaves. The flowers are diœcious, and very small. The tree is a native of the countries bordering upon the Mediterranean. The fruit yields by expression a fixed oil, of a deep green color, and liquid at about 32.3° C., which the Arabs use both as an article of diet and for light. A resinous exudation from the stem and branches is the official part, but it does not appear to be collected in all places where the tree flourishes. Under the names of *Bombay mastic* and *East Indian mastic,* there occur in India masses of oleoresin said to be derived from the *Pistacia Khinjuk* Stokes and probably other species of *Pistacia,* having the general appearance of true mastic with a darker color, but lacking fragrance, and dissolving in hot alcohol.

The mastic imported into the United States and Great Britain is obtained only from the island of Scio, or Chios, in the Grecian Archipelago, where the tree is cultivated for this product. Incisions are made in the trunk and principal branches, from which the juice slowly exudes, and either hardens in tears upon the bark, or drops on the ground, where it is received upon cloths or the bare earth, and concretes in irregular masses. The tears are most esteemed, and are the only form recognized by the N. F. They are of various sizes, oval or roundish, often compressed, smooth, semi-transparent, of a pale-yellow color, of a shining fracture, friable, and usually covered with a whitish powder, occasioned by their friction against each other. They are brittle, but unlike Sandarach become plastic when chewed. The masses consist of yellowish agglutinated tears, with others of a darker color and less translucent, and often fragments of wood, bark, or earthy matter intermingled.

According to J. Léon Subeiran, the valuable tears are produced by spontaneous exudation from the branches. But the greater part of the resin comes from longitudinal incisions in the stem, made with a knife, close together and extending from the root to the branches. In fifteen or twenty days the resin has concreted, and is collected in little panniers of white paper or cotton cloth. (*Proc. A. Ph. A.,* 1897, 563.)

Chian turpentine, which is also collected in the island of Chios, as well as in Cypress, is from the *Pistacia Terebinthus.* It is a thick tenacious liquid varying from yellow to green in color, with an odor similar to but more pleasant than, that of turpentine. On exposure to air it thickens into a translucent yellowish mass.

For description of the mode of production, etc., see *Proc. A. Ph. A.,* 1897, p. 563. It was recommended by Clay, of England in 1880 as a local application for *uterine cancers.*

Description and Physical Properties.—"In sub-globular, lenticular, elongated or pear-shaped tears, about 3 mm. in diameter, pale yellow or greenish yellow, transparent, having a glass-like luster, the surface sometimes very slightly dusty; brittle, becoming plastic when chewed. Odor slight, balsamic; taste mild, terebinthinate.

"Not less than 97 per cent. of Mastic is soluble in ether and not less than 80 per cent. is soluble in alcohol. The acid number is not less than 50." *N. F.*

Mastic is nearly inodorous, unless rubbed or heated, when it becomes fragrant. Its taste is weak, but agreeably terebinthinate, and, after long chewing, very slightly acrid. It is at first friable under the teeth, but soon becomes soft and ductile, and acquires a white, opaque appearance. Its sp. gr. is 1.074. It is fusible and inflammable by heat.

Alcohol dissolves about 90 per cent. of it. The insoluble residue is a viscid substance which becomes brittle when dried, and for which the name of *masticin* or *betaresin of mastiche* has been proposed. This substance, though not dissolved by alcohol, softens and swells up in it, as gluten does in water. Hlasiwetz gives $C_{20}H_{31}O$ as the formula of the resin. The portion dissolved by the alcohol is called by Johnston *alpha resin of mastiche* or *mastichic acid* because of its acid properties, and has the formula $C_{20}H_{32}O_2$. (*Handwörterbuch der Chemie,* iv, p. 280.) Schimmel & Co. (*Schim. Rep.,* April, 1897) state that mastic resin yields from 0.9 to 2.5 per cent. of a powerful balsamic essential oil of the same odor as the raw material, a sp. gr. of from 0.855 to 0.87 at 15° C., and an optical rotation (100-mm. tube) of from $+22°$ to $+27°$. Tschirch and Reutter (*A. Pharm.,* 1904, 104) examined mastic carefully; they found approximately 42 per cent. of free resin acids. These are: the isomeric α- and β-masticinic acids, $C_{23}H_{36}O_4$, *masticolic acid,* $C_{23}H_{36}O_4$ (slight amount), amorphous α-masticonic acid, $C_{32}H_{48}O_4$ (20 per cent.), and β-masticonic acid, $C_{32}H_{48}O_4$ (18 per cent.). Besides this, mastic contains 30 per cent. α-masticoresin, $C_{35}H_{36}O_4$, soluble in alcohol; 20 per cent. of β-masticoresin (masticin), insoluble in alcohol, and 2 per cent. of an ethereal oil, possessing a pale yellow color and a somewhat camphoraceous odor. Finally, there is also a bitter principle, which could not be isolated in pure form. For a chemical investigation of Egyptian mastic by Reutter, see *S. W. P.,* 1913, 537.

Mastic is occasionally adulterated with olibanum, sandarach, and other resinous bodies, and, in seasons of scarcity, with sea salt.

Uses.—Mastic was formerly thought to possess properties analogous to those of the turpentines, and was used in *debility of the stomach, hemoptysis* from ulcerations, *leucorrhea, chronic diarrhea,* etc.; but its virtues were overrated, and it is at present scarcely ever given internally except in certain cathartic pills. In the East, however, an aqueous infusion is said to be still used in *cholera infantum.* Dissolved in alcohol or oil of turpentine, it forms a brilliant varnish. A solution made by macerating half an ounce of mastic and fifteen grains of caoutchouc in two fluidounces of chloroform, and filtering in closed vessels, forms a valuable *varnish* for microscopic work. The following mode of applying it to carious teeth has been recommended. Dissolve four parts of mastic in one of ether, in a bottle well stoppered. With the solution thus formed, which is yellow and of an oily consistence, saturate a small piece of cotton of the size of the carious cavity, and, having well cleansed and dried the cavity, introduce the cotton, without painful pressure, so as to fill it exactly. The resin attaches itself to the diseased surface of the tooth, which it protects from the air, and from the food taken into the mouth. It has been highly recommended by various surgeons as a dressing for wounds. Its use is chiefly for the purpose of preventing bacteria upon the surrounding skin getting into the wound. Voos (*M. M. W.,* 1911) paints the skin up to the edges of the wound without previous washing, with a solution of mastic in benzol and then cleanses the wound in the ordinary manner and applies an aseptic dressing. A *mastic varnish,* made with chloroform, is official in the N. F. Another preparation of a similar nature is upon the market under the name of *mastisol.*

Dose, thirty grains (2 Gm.).

Off. Prep.—Pilula Aloes et Mastiches, *N. F.;* Solutio Mastiches Chloroformica, *N. F.*

MATICO. N. F.

MATICO Matic.

"Matico is the dried leaf of *Piper angustifolium* Ruiz et Pavon (Fam. *Piperaceæ*). Matico contains not more than 5 per cent. of stems, flower spikes or other foreign organic matter, and yields not more than 6 per cent. of acid-soluble ash." *N. F.*

Feuilles de matico, *Fr. Cod.;* Maticoblätter, *G*

Piper angustifolium is a shrub with a jointed stem and 4-angled branches about twelve feet in height. The leaves are short-petioled, alternate and lanceolate with finely scalloped margins, acute apex, subcordate base and tessellated upper surface. The flowers are small, yellow in color and borne in slender axillary spikes. The fruit is a small, reddish-brown drupe containing a single seed. The plant is a native of Peru, where the fruit, under the name of *thohothoho,* is employed in the same manner as cubeb. This species is also found in other parts of South America. The commercial drug matico is furnished, according to G. Dethan and R. Bertault (*J. P. C.,* 1897, 537), by two varieties of *Piper angustifolium*—viz., *α-cordulatum* (*Artanthe elongata* Miq.), and *β-ossanum,* which differ somewhat in the shape of the leaves. The former has the leaves larger, shorter, and broader, with an oblique cordate base. The midrib of *α-cordulatum* is much less convex below than in the other variety. The leaves of other species of *Piper* have occasionally been found admixed with commercial lots of matico.

Description and Physical Properties.—"*Unground Matico.*—Usually in compressed, matted masses with leaves more or less broken;

leaves short petiolate, lanceolate, about 4 times as long as broad, from 10 to 20 cm. in length and from 2 to 5 cm. in breadth; apex tapering and acute; base slightly unequal, cordate, margin finely crenulate; upper surface dark green, distinctly tessellated; lower surface pale green, reticulate with prominent, yellowish brown midrib and veins forming small quadrangular meshes clothed with matted pubescence. Odor distinct, aromatic; taste pungent, pepper-like.

"*Structure.*—Epidermis of the upper side composed of regular polygonal cells and of the lower side of somewhat irregular and undulate cells, especially where covering the veins; numerous stomata, with large neighboring cells, on the lower side; the hypodermis of one or more rows of cells and palisade cells in 2 or 3 rows; loose spongy tissue; outer layer of mid-rib of thick-walled cork cells; secretion cells filled with yellow oil; upper surface with papillæ and few bristly hairs; hairs of the lower surface of two kinds, the one, 6 to 10 cells in length, pointed, bent and matted, having thick walls and a striate cuticle; the other, bristle hairs of one stem cell and a head cell; calcium oxalate crystals few in parenchyma tissue of the venation, in the form of raphides or monoclinic prisms.

"*Powdered Matico.*—Greenish yellow; exhibits the characteristic multicellular non-glandular hairs having enlarged joints, up to 0.9 mm. in length; polygonal epidermal cells; fragments of irregular epidermal cells with stomata, the latter up to 0.030 mm. in length, and secretion cells of the leaf." *N. F.*

In 1864 Bentley (*P. J.*, Jan., 1864) described a *false matico* from Central America believed to be yielded by the *Piper aduncum* L. It is distinguished by the want of the reticulations on the upper, and the down on the under, surface which characterize true matico. (See also Thoms, *Arbeiten a. d. Pharm. Institut d. Universität, Berlin,* 1910, p. 70.) The most recent adulterant and substitute is the leaves of *Eupatorium glutinosum* Lam. (Fam. *Compositæ*). These differ from matico in being opposite, with serrate margin, cordate base, coarsely bullate upper surface and numerous glandular hairs (*S. R. A.*, xxiii, 1918, p. 97).

The medicinal properties of matico probably reside in the volatile oil of which it yields from 1 to 3.5 per cent. Both Flückiger and Kugler (*A. J. P.*, 1884, 477) reported that when the oil of matico was allowed to stand in a cold place it deposited a crystalline substance, which has been known as *matico camphor.* Apparently, however, the oils of today do not contain this camphor but some of them yield the solid *asarone.* Thoms (*A. J. P.*, 1904, p. 584) found apiol in an oil known to be from the *P. angustifolium,* but neither matico camphor nor asarone. Marcotte in 1864 reported the presence of a crystallizable acid which he called "artanthic" acid, but its existence has not been confirmed by other investigators. There are a variety of "oils of matico" on the market.

Uses.—A South American tradition attributes the name of this herb to a Spanish soldier named Matico, of the eighteenth century, who applied the leaves to a wound with an arrest of hemorrhage. The term "soldier's tree" as well as "matico" has been applied to other plants, notably the *Eupatorium glutinosum,* about which similar tales are current. It was introduced into European medicine by Jefferys in the early part of the nineteenth century. As a local application matico has been used as a stimulating astringent in *ulcers* and *chronic catarrhs,* especially leucorrhea, or to arrest *hemorrhages.* Internally it has been given in the treatment of *diarrheas,* and also in catarrhs of the genito-urinary organs. The powder is sometimes used, but the fluidextract (see Part III), is preferable for internal administration.

Dose, forty-five to seventy-five grains (3–5 Gm.).

Off. Prep.—Fluidextractum Matico, *N. F.*

MATRICARIA. N. F.

MATRICARIA Matricar. [German Chamomile]

"Matricaria is the dried flower-head of *Matricaria Chamomilla* Linné (Fam. *Compositæ*). Matricaria contains not more than 5 per cent. of stems or other foreign organic matter, and yields not more than 4 per cent. of acid-insoluble ash." *N. F.*

Flores Chamomillæ; Horse Gowan, Dog's Camovyne; Camomille commune (d'Allemagne), *Fr.;* Flos Chamomillæ, *P. G.;* Kamillen, Kamillenblumen, *G.;* Camomilla commune, *It.;* Manzanilla (Flor de), *Sp.*

Matricaria Chamomilla is an annual plant, with a branching stem a foot or two in height, bearing alternate leaves, the lower being tripinnate, the upper bipinnate or simply pinnate, and all of them very green, and nearly or quite smooth. The leaflets are linear and very small. The flower-heads appear singly at the ends of the stem and branches. The bracts of the involucre are obtuse, green in the middle, and whitish, membranous, and translucent at the margin. The ray-florets are pistillate, white, at first spreading, and ultimately reflected. The disk is of a deep yellow color, at first flat, but in the end convex, and in some cases somewhat conical. The plant is a native of Europe and Western Asia, and is occasionally cultivated in our gardens. It is also naturalized in North America, Central America and Australia. Mitlacher gives the results of methods of cultivating matricaria in *Zeit. Oest. Apoth. Ver.*, l, p. 410. Meyer has suggested (*Pharm. Zeit.*, lviii, p. 790) the practicability of scientifically collecting matricaria from the wild grown plants. All parts of it are active, but the flower heads only are official. These are gathered from May to August and shrink in drying, so that they are scarcely half as large as in their recent state. Matricaria is shipped to the United States in cases chiefly from Budapest, Szeged, Hamburg and Trieste.

The 1924 supply of this drug was of exceptionally good quality. Siftings consisting of ray and disk florets are imported into this country in bags.

Description and Physical Properties.—"*Unground Matricaria.*—Flower-heads composed of a few white ray-florets and numerous yellow disk-florets on conical, hollow receptacles, the latter being from 3 to 10 mm. in breadth; disk-florets tubular, perfect, and without a pappus; ray-florets from 10 to 20, pistillate, corolla white, 3-toothed and 4-veined, usually reflexed; involucre hemispherical, composed of from 20 to 30 imbricated, oblanceolate, and pubescent scales; peduncles light green to brownish green, longitudinally furrowed, more or less twisted and attaining a length of 2.5 cm.; achenes somewhat obovoid and faintly 3- to 5-ribbed; pappus none, or only a slight membranous crown. Odor pleasant, aromatic; taste aromatic and bitter.

"*Powdered Matricaria.*—Yellowish brown; exhibits numerous spinose, spherical or triangulate pollen grains with 3 pores, and up to 0.025 mm. in diameter; fragments of corolla from ray-florets with papillate epidermal cells; few short glandular hairs; fragments of achene tissue with epidermal cells having scalariform markings or wavy longitudinal walls and parenchyma containing rosette aggregates of calcium oxalate, the latter up to 0.010 mm. in diameter; fragments of characteristic tissue of anthers composed of elongated cells with scalariform walls; fragments of stigmas, the upper end bearing characteristic papillæ; vascular bundles with tracheæ having spiral, annular, or reticulate markings; fragments of the involucral scales bearing porous fibers, tracheæ and elliptical stomata, the latter up to 0.030 mm. in length.

"Preserve Matricaria in tightly closed containers." *N. F.*

"The similar flower-heads of *Anthemis arvensis* L., and *Maruta Cotula* De Candolle (Fam. *Compositæ*), have conical, solid, and chaffy receptacles." *U. S. VIII.*

In addition to the above it is sometimes admixed with the flower-heads of other European species of *Anthemis.* The flowerheads of the common daisy (*Chrysanthemum Leucanthemum* L.) as well as other species of *Chrysanthemum* have been present in the drug of commerce. G. Edman states the adulterant most commonly employed to be the flowers of one or more species of *Artemisia.* He has made careful microscopic examination of the flowers from six *Artemisia* species and describes his findings in detail (*Svensk. Farm. Tidskr.,* xxvi, 1922, p. 229).

The dried flowers of matricaria are considerably smaller than those of dog fennel, and exhibit a larger proportion of the disk-florets compared with those of the ray.

Matricaria contains a volatile oil and a bitter substance. The oil, which is obtained by distillation with water, is thick, somewhat tenacious, of a fine deep blue color becoming green and brown by age, and almost opaque in mass. Though supposed by Gerhardt to be identical with the oil of chamomile (*Anthemis nobilis*), it has been shown to be distinct. It congeals at – 20° C., has the sp. gr. 0.920 to 0.955, and contains a terpene, $C_{10}H_{16}$, *chamomillol,* $C_{10}H_{16}O$ and *trichamomillol,* $C_{30}H_{48}O_3$, the latter being the portion of the oil which possesses the blue color. *Schimmel & Co.'s. Report* for April, 1897, states that the German chamomile oil contains a paraffin hydrocarbon, which was obtained as a snowy white solid melting at 53° to 54° C. The blue color has also been stated to be due to a volatile principle called *azulene* by Piesse, and *cærulein* by Gladstone and others; also found in oil of absinthe, yarrow and some other blue volatile oils. This, when distilled with potassium, yields a terpene, $(C_{10}H_{16})_3$, and with phosphoric oxide a hydrocarbon, $C_{10}H_{14}$. (Kachler, *Ber. d. Chem. Ges.,* iv, 36.)

Uses.—Matricaria is a mild tonic, very similar to chamomile in medicinal properties, and, like it, in very large doses an emetic. It is considered also in Europe to be antispasmodic and anthelmintic. It is much employed in Germany, but in this country scarcely at all, unless by German practitioners. It may be given for the same purposes and in the same manner as chamomile.

Dose, half an ounce (15.5 Gm.).

Off. Prep.—Species Emollientes, *N. F.*

MEL. U. S.

HONEY

[Mel Depuratum, U. S. IX, Clarified Honey]

"A saccharine substance, gathered mostly from the nectar of flowers, and deposited in the honeycomb by the bee, *Apis mellifera* Linné (Fam. *Apidæ*). It must be free from foreign substances such as parts of insects, leaves, etc." *U. S.* "Purified Honey is honey of commerce melted and strained, the specific gravity, if necessary, being adjusted to 1.36 by the addition of Distilled Water." *Br.*

Mel Depuratum, *Br.;* Purified Honey; Mel Despuruatum; Miel, *Fr. Cod.;* Mel, *P. G.;* Honig, *G.;* Miele, *It.;* Miel, *Sp.*

The U. S. IX recognized two forms of honey; the commercial substance and one purified by dissolving in water, adding shredded paper pulp and filtering and evaporating the water, and adding glycerin to prevent crystallization. The improvement in the commercial article has made unnecessary the process of purification and the present revision agrees with the Br. in describing only one although under a different title.

From the nectaries of various flowers the bee and other insects extract a thin, aqueous fluid, nearly without flavor and insipidly sweet, usually known as *nectar.* As honey is made out of this substance it is very much affected by the character of the nectar, so that the nature of the plants which predominate in the vicinity of the hive is a matter of great importance to the bee culturist, not only in regard to the flavor of the honey which is yielded, but even to its freedom from poisonous qualities, cases having been reported from time to time of poisoning produced by the eating of honey which had not been tampered with after extraction from the hive. In the United States honey made by the bee from the flowers of the Mountain Laurel (*Kalmia*) is especially poisonous. See *N. J. M. R.*, 1852, 46; "*Poisonous Honey*," by L. F. Kebler, *Proc. A. Ph. A.*, 1896, 167; H. Bley, *Ph. Ztg.*, Nov., 1885. The latter states that *Datura Stramonium* and *Gelsemium* are for honey making especially dangerous plants. The nectar when taken in by the bee is chemically changed by secretions from glands in the head and thorax; levulose, dextrose, and, rarely, sucrose being formed. The finest honey is that which is allowed to drain from the comb. As beeswax is a valuable product in itself, modern centrifugal extractors are now employed by apiculturists to separate the honey from the comb, after cleanly slicing off the ends of the cells with a sharp knife. Centrifuged honey is much cleaner than that produced by other methods. If obtained from hives that have never swarmed, it is called *virgin honey*. An inferior kind is procured by submitting the comb to pressure, and if heat be employed previous to expression, the product is still more impure. The honey which is most highly esteemed is that made from the nectar of the white clover blossom. Equally valuable is the honey derived from raspberry blossoms and bass-wood flowers. The honey made late in the summer from the flowers of the buckwheat is darker in color. The largest producer of honey in the United States is California. The United States is said to be the greatest honey producing region on the globe, the annual production being between 60,000,000 and 75,000,000 pounds. Nearly 2,000,000 pounds of wax are also produced in this country.

The former method for clarifying honey was as follows:

"Honey, *a convenient quantity*, Distilled Water, Glycerin, each, *a sufficient quantity*. Weigh the honey in a tared dish, mix it intimately with *two per cent.* of paper pulp, which has been previously reduced to shreds, thoroughly washed and soaked in water, and then strongly expressed and again shredded. Then heat on a water bath at a temperature not exceeding 70° C., and carefully remove the scum which rises to the surface. Add enough distilled water to make up the loss incurred by evaporation, strain, and mix the strained liquid with *five per cent.* of its weight of glycerin." *U. S.*

For other methods of clarification, see *U. S. D.*, 20th ed., p. 691.

In the recent state honey is fluid, but on being kept it is apt to form a crystalline deposit, and to be ultimately converted into a soft granular mass. In commerce it is found of every consistence, from that of a viscid liquid, like thin syrup or oil, to that of lard or soft suet. Its color is sometimes white, but usually yellowish, and occasionally of a brownish or reddish tinge. It has a peculiar agreeable odor, varying somewhat with the flowers from which it was collected, and a very sweet, feebly aromatic taste, which is followed by a slight prickling or sense of acridity in the fauces. Cold water dissolves it readily, alcohol with less facility.

Description and Physical Properties.—"A thick, syrupy liquid of a light yellowish or yellowish-brown color. It is translucent when fresh, but frequently becomes opaque and granular from crystallization of dextrose. It has a characteristic odor and a sweet, faintly acrid taste.

"Honey is lævorotatory at 20° C., and is slightly acid to litmus paper. Diluted with twice its weight of water, Honey is only moderately turbid, is not stringy, and has a specific gravity of not less than 1.099 at 25° C. Incinerate about 2 Gm. of Honey, accurately weighed, at a low temperature in a platinum crucible, in small portions at a time: not more than 0.3 per cent. of ash remains. A solution of 10 Gm. of Honey in 50 cc. of distilled water requires not more than 0.5 cc. of normal sodium hydroxide for neutralization, phenolphthalein T.S. being used as indicator. Ten cc. portions of a filtered aqueous solution of Honey (1 in 10) show no more *chloride* than corresponds to 0.2 cc. of fiftieth-normal hydrochloric acid and no more *sulphate* than corresponds to 0.2 cc. of fiftieth-normal sulphuric acid, page 462. Boil about 2 Gm. of Honey with 20 cc. of water, cool, and add 2 drops of iodine T.S.: no blue, green, or reddish color is produced (*starch or dextrins*). The color of an aqueous solution of Honey (1 in 2) is not immediately changed when mixed with an equal volume of ammonia T.S. (*foreign coloring matter*), and a 5 cc. portion does not at once acquire a red or rose color on the addition of a few drops of hydrochloric acid (*azo dyes*). Triturate about 1 Gm. of Honey with 20 cc. of ether in a mortar, filter into a porcelain dish or crucible, allow the ether to evaporate, and add to the residue one drop of resorcinol T.S. At most only a pink color is produced, which disappears in half a minute, but not an orange, cherry, or brown-red color (*artificial honey or added invert sugar*)." *U. S.*

The British Pharm. describes it as "a syrupy, translucent, pale yellowish liquid. Aromatic odor; taste at first sweet, afterwards faintly acrid. Specific gravity 1.36. *Optical rotation* at 15.5° C. of a solution in *water*, containing 25 grammes in 100 millilitres, decolorised by filtration with *animal charcoal*, in a tube 200 millimetres long, between 0° and –5° C.; 5 millilitres of the same solution when fixed with 15 millilitres of *absolute alcohol* do not become more than faintly opalescent (absence of starch sugar). When 2 grammes are dissolved in 20 millilitres of boiling *water* and cooled, the solution does not become blue on the addition of one drop of *N/10 solution of iodine* (absence of starch). Ash not more than 0.25 per cent.; solution of the ash in *water* is not alkaline to *litmus,* and when acidified with *nitric acid* yields not more than a very faint opalescence with *solution of barium chloride,* or with *solution of silver nitrate* (limit of sulphates and of chlorides)." *Br.*

Genuine honey varies somewhat in its composition. The principal constituents are a mixture of dextrose and levulose in the same proportions as present in artificial invert sugar and in an amount ranging from 65 per cent. to nearly 80 per cent. Sucrose is present in from ½ per cent. to 8 per cent. The ash of honey varies from 0.3 per cent. to 0.50 per cent. and the water from 12 per cent. to 33 per cent. In a standard honey the sucrose should not be over 8 per cent., the water not over 25 per cent. nor the ash over 0.25 per cent. Honeys obtained by bees feeding upon the saccharine exudations of coniferous trees have been found to contain dextrose as the preponderating sugar and to have a dextrorotatory optical rotation instead of lævorotatory, as in the ordinary varieties. Such honeys usually come from foreign countries, although several specimens have been reported from the western part of the United States, and one specimen containing melezitose was reported from Pennsylvania, this rare carbohydrate having originated as an exudation on the twigs of *Pinus virginiana.*

According to Wm. A. Selser, who separated wax from honey on a large scale, the proportion of wax in the honey comb averages 1 per cent.; from 1500 pounds he obtained 14¼ pounds of wax by actual experiment. (*A. J. P.,* 1904, 267.)

A large number of samples of genuine honey analyzed in 1897 for the Department of Inland Revenue, Canada (Bull. 47), showed the following variations:

Direct polarization, –2.4 to –19.
Invert polarization, –10.2 to –28.
Sucrose (by Clerget), 0.5 to 7.64 per cent.
Invert sugar, 60.37 to 78.8 per cent.
Water, 12 to 33 per cent.
Ash, 0.03 to 0.50 per cent.

Neufeld in *Der Nahrungsmittelchemiker als Sachsverständiger,* Berlin, 1907, p. 275, gives the following limits for pure honey of European origin:

Water	8.30 to 33.59 per cent.
Protein	0.03 to 2.67 per cent.
Invert sugar	49.59 to 93.96 per cent.
Sucrose	0.10 to 10.12 per cent.
Dextrin	0.99 to 9.70 per cent.
Formic acid	0.03 to 0.21 per cent.
Ash	0.02 to 0.68 per cent.

Browne has published a comprehensive article on American honey (*U. S. Dept. Agric., Bur. of Chem., Bull.* 110, 1908) of which the tabular analyses are given in Leach, "*Food Inspection and Analysis,*" 3d ed., p. 635.

Künnmann and Hilger (*A. J. P.,* 1896, 570) state that dextrin is present in all honey, whether dextrorotatory or lævorotatory, and claim to have identified it as achroö-dextrin. Müllenhoff believes that the honey is preserved in the sealed cells of the comb by the secretion with it of a minute quantity of formic acid, and has found by experiment that the addition of one part of 25 per cent. formic acid is sufficient to keep permanently 250 parts of honey, but in this connection it should be remembered that the absence of contact with the air would account for the preservation of honey in the comb.

Honey is sometimes adulterated with artificial glucose. This cannot be detected by the official tests with certainty, but the safest method is to employ the polariscope. (See Leach, "*Food Adulteration and Analysis.*")

According to Oscar Haenle, glucose can also be detected by first dialyzing thoroughly and then polarizing, under which circumstance, if glucose be present, rotation to the right occurs; if the honey be pure the light is not affected. Undialyzed honey ordinarily polarizes to the left, but unadulterated conifer honeys are dextrogyrate. (*P. J.,* xxi.)

Honey has been frequently adulterated with artificial invert sugar. This is best detected by the official method given above.

Uses.—Honey is a valuable foodstuff; not only on account of its characteristic flavor but chiefly because it consists largely of invert sugar, and is therefore more rapidly absorbed, it is often more acceptable to the stomach than cane sugar. In medicine it is sometimes used as a flavoring agent especially for gargles. Its recognition by the Pharmacopœia, however, is because of its employment in certain pharmaceutical processes, especially in the preparation of blue mass.

Dose, one to four fluidrachms (3.75–15 cc.).

Off. Prep.—Confectio Piperis, *Br.;* Mel Boracis, *Br.;* Mel Rosæ, *U. S.;* Oxymel, *Br.;* Confectio Rosæ, *N. F.;* Mel Sodii Boratis, *N. F.*

MEL BORACIS. Br.

BORAX HONEY

Mel Sodii Boratis, *U. S.* 1870; Honey of Borax, Honey of Borate of Sodium; Miel boraté, Mellite de Borax, *Fr.;* Boraxhonig, *G.*

"Purified Borax, in powder, 10 *grammes;* Glycerin, 5 *grammes;* Purified Honey, 85 *grammes.* Mix." *Br.*

This preparation was very properly dropped from the U. S. Pharmacopœia at the 1880 revision, but is recognized by the N. F. V, the formula being identical with the British process given above. Borax honey is used in the *thrush* of infants and in *aphthous ulcerations* of the mouth.

MEL ROSÆ. U. S.

HONEY OF ROSE

Mellitum Rosatum; Mellite de Rose rouge, *Fr. Cod.;* Miel Rosat, *Fr.;* Mel Rosatum, *P. G.;* Rosenhonig, *G.;* Miele rosatol *It.;* Miel de rosas, *Sp.*

"Fluidextract of Rose, 120 cc.; Honey, a sufficient quantity, to make 1000 Gm. Mix the fluidextract of rose in a tared vessel with enough honey to make the product weigh 1000 Gm." *U. S.*

Though one of the official preparations in the London and Edinburgh Pharmacopœias, the Honey of Rose has been dropped in the British. As is well known, honey of rose deposits honey sugar upon standing even but a short time. Touflet (*Ph. Centralh.*, xxxvi, 307) obviates this precipitation in the following manner: Take of Powdered Rose Leaves, 25 parts; Alcohol, sp. gr. 0.875, 75 parts; Honey, 80 parts; Sugar, 34 parts. Percolate the rose leaves with the alcohol, filter and distil off the filtrate to 40 parts. To this add the honey and sugar, and bring to the boiling point.

Honey of rose forms a pleasant addition to the gargles employed in *inflammation* and *ulceration* of the *mouth* and *throat*. It is official because of its use in blue mass.

Dose, one fluidrachm (3.75 cc.).

Off. Prep.—Mel Rosæ et Sodii Boratis, *N. F.*

MELILOTUS. N. F.

MELILOT Melilot. [Yellow Melilot, Yellow Sweet Clover]

"Melilot consists of the dried leaf and flowering top of *Melilotus officinalis* (Linné) Lamarck (Fam. *Leguminosæ*). Melilot contains not more than 3 per cent. of its stems over 3 mm. in diameter, or other foreign organic matter." *N. F.*

An annual or biennial plant indigenous to Europe but naturalized in the United States, where it frequently abounds on waste ground and in fields. It bears alternate, trifoliate leaves with obovate to oblong leaflets whose apex is either rounded, truncate or slightly notched and margin closely serrate The flowers are small and yellow, occurring in spicate racemes. The fruit is an obovate, one-seeded legume. The plant, when in flower, has a peculiar sweet odor, which, by drying, becomes stronger and more agreeable, somewhat like that of the tonka bean.

Description and Physical Properties.—"*Unground Melilot.*—Stems mostly less than 3 dm. in length, slender, straight, mostly simple, often leafy below, terminating in long slender racemes, the younger portions very finely pubescent; leaves glabrous or nearly so; petiolate, trifoliate, stipulate, the stipules subulate, entire, the leaflets, from 1 to 3 cm. in length, varying from narrowly oblong to oval or occasionally broader above the middle, rounded, truncate, or slightly notched at the summit, sharply serrate; racemes 1 dm. or less in length, many flowered, the flowers yellow, from 5 to 6 mm. in length; calyx bell-shaped, the five, nearly equal lobes shorter than the tube, corolla papilionaceous, the keel shorter than the other petals, which are about equal; legumes reflexed, from 2.5 to 3.5 mm. in length, obovate, wrinkled, one-seeded. Odor aromatic, tonka-like; taste sweetish, slightly pungent and bitter.

"*Powdered Melilot.*—Light green; numerous uniseriate, 3-celled non-glandular hairs from 0.130 to 0.385 mm. in length, the two lower cells usually small and thin-walled, the upper cell much elongated, pointed and with thick, roughly spinose walls; fragments of leaf tissue composed of epidermal cells with broadly elliptical stomata the latter from 0.020 to 0.035 mm. in length; fragments composed of chlorenchyma and fibro-vascular tissue associated with crystal fibers containing prisms of calcium oxalate, the latter from 0.010 to 0.020 mm. in length; portions of stem tissue composed of wood and pith parenchyma, fibers and tracheæ with spiral markings or simple pores; pollen grains ellipsoidal, from 0.022 to 0.032 mm. in diameter; occasional glandular hairs consisting of 2- to 3-celled stalks and multicellular heads." *N. F.*

The pleasant odor of melilotus is due to the presence of coumarin (see *Coumarinum*). It is present in melilot, combined with *melilotic* (*hydrocoumaric*) *acid*, $C_9H_{10}O_3$ and *coumaric acid*, $C_9H_8O_3$, of which latter acid *coumarin* is the anhydride.

Uses.—Melilotus has been attributed with analgesic properties and consequently employed in *neuralgias*. The evidence of any therapeutic virtue, however, is far from convincing.

Off. Prep.—Species Emollientes, *N. F.*

MENTHA PIPERITA. U. S.

PEPPERMINT Menth. Pip.

"Peppermint consists of the dried leaves and tops of *Mentha piperita* Linné (Fam. *Labiatæ*). Peppermint contains not more than 2 per cent. of stems over 3 mm. in diameter, or other foreign organic matter." *U. S.*

American Mint, Brandy Mint; Menthe poivrée, *Fr.*; Folia Menthæ Piperitæ, *P. G.*; Pfefferminzblätter, *G.*; Menta piperita, *It.*, *Sp.*; Herba Menthæ.

The genus *Mentha* comprises at least fifteen species, of which there are also a great many varieties. Some of the mints have been in use for culinary and medicinal purposes since antiquity, but no well-defined distinction is made as to just what plants were employed. It is stated that *M. piperita* L., the most important member of this genus, was long ago cultivated by the Egyptians. It is mentioned in the Icelandic Pharmacopœia of the thirteenth century. Peppermint is now grown in considerable amounts in Europe, North America, and Eastern Asia and is also found growing wild in other parts of the world, as South America and Australia. The oldest existing peppermint district is in the neighborhood of Mitcham (Surrey), England. The chief peppermint plantations of the United States are in Michigan, the western part of New York, Ohio and Indiana. The best peppermint comes from Michigan, Northern Indiana and Germany. Inferior peppermint, containing from 30 to 50 per cent. of spearmint, has recently been received from Virginia and North and South Carolina. (See Russell, *Spatula*, 1921, xxvii, 481.) On the continent of Europe other species of *Mentha* (particularly *M. arvensis*) grow with *M. piperita,* deteriorating the product. In America other plants (as *Erigeron canadensis* and *Erechthites hieracifolia*) cause the same trouble. Besides *M. piperita* other species are cultivated, as some Asiatic varieties of *M. arvensis, M. spicata, M. longifolia* (var. *undulata*), *M. gentilis, M. dalmatica,* and *M. Pulegium.* Miss Henkel reviews the situation regarding the cultivation of peppermint in the United States and describes the three kinds of mint grown for the production of peppermint oil: *Mentha piperita* L.; *Mentha piperita vulgaris* Sole, and *Mentha piperita officinalis* Sole. (*Bul. Bur. Plant Ind., U. S. Dept. Agric.,* No. 90, 1906.) A comprehensive article on the cultivation of peppermint in Japan by Inouyé is in *Schim. Rep.,* November, 1908, p. 199. Peppermint has recently been successfully grown in Wisconsin. (*Paint, Oil and Drug Rev.,* xliv, p. 18.) The cultivation of peppermint is a growing industry on the reclaimed lands of Louisiana. (*Spatula,* xvii, p. 18.) (For accounts of the cultivation of peppermint in Germany, see Thoms in *B. P. G.,* xx, p. 244; in Austria, see Mitlacher, *Ph. Post,* xliv, p. 215; *Zeit. Oest. Apoth. Ver.,* l, p. 422; and in Russia, see *Proc. A. Ph. A.,* 1902, 831.) It has been repeatedly pointed out that the essential oil-bearing plants of the *Labiatæ* are very capricious and constantly changing character with change of soil and climate.

Peppermint is a perennial herb native to low wet soils of Europe. It produces prolific creeping stolons from which arise numerous quadrangular, purplish erect stems which branch toward the top. The leaves are opposite, petiolate, ovate, sharply serrate, pointed, smoother on the upper than on the under surface, and of a dark green color above, paler beneath. Its small purple flowers occur both in terminal, obtuse spikes, and in paired axillary cymes, the latter only in the upper leaf axils. The calyx is tubular, often purplish, furrowed, glabrous below, and five-toothed, the teeth being hirsute. The corolla is purplish, tubular, with its border divided into four segments, of which the uppermost is broadest, and notched at its summit. The four short stamens are concealed within the tube of the corolla; the style projects beyond it, and terminates in a bifid stigma. The fruit consists of four ellipsoidal nutlets. The plant should be cut for medicinal use during the dry periods of summer, while in flower. Two varieties of peppermint occur under cultivation in the United States and Europe, viz., *white mint* and *black mint.* White mint or *M. piperita* var. *officinalis* Sole is slender, one to two feet in height with light colored stems and leaves. Black mint or *M. piperita* var. *vulgaris* Sole is stout, two to three feet in height with usually purple-colored stems and dark green foliage. John C. Umney points out differences between white and black peppermint in *P. J.,* 1896, 123.

Description and Physical Properties.—"*Unground Peppermint.*—Leaves more or less crumpled and frequently detached from the stem; ovate-oblong to oblong-lanceolate, petiole from 4 to 15 mm. in length, slightly pubescent, blade from 1 to 9 cm. in length, acute and sharply serrate, light green to purplish-brown; upper surface nearly glabrous, lower surface glandular-hairy, especially on the veins; stem quadrangular, from 1 to 3 mm. in diameter, glabrous except for a few scattered deflexed hairs; flower-whorls usually in a compact, oblong or oval spike, from 1 to 1.5 cm. in breadth, rounded at the summit, and in fruit attaining a length of from 3 to 7 cm.; bracts oblong-lanceolate, from 4 to 7 mm. in length; calyx tubular, equally 5-toothed, pubescent and glandular-punctate, often dark purple in color; corolla tubular-campanulate, 4-cleft, about 3 mm. in length and often light purple; stamens 4, short and equal; nutlets ellipsoidal, about 0.5 mm. in diameter, blackish-brown; odor aromatic, characteristic; taste aromatic, pungent, followed by a cooling sensation in the mouth.

"*Powdered Peppermint.*—Green fragments of leaf epidermis with wavy vertical walls and, if from the lower surface of the leaf, with numerous stomata and glandular and non-glandular hairs, especially along the veins; glandular hairs with a 1- to 2-celled stalk and 1- to 8-celled head, usually set in a depression in the leaf and containing volatile oil and frequently yellowish or brownish crystals which refract polarized light; non-glandular hairs with thin, papillose walls, 1 to 8 cells long, the terminal cell pointed or sometimes globular; fragments of chlorenchyma with vascular tissue, the tracheæ spiral or with simple pores and but slightly lignified; fragments of collenchyma and of thin-walled, non-lignified fibers associated with parenchyma; pollen grains spheroidal and smooth." *U. S.*

For a paper on the histology of powdered peppermint by Smith Ely Jelliffe, see *D. C.,* 1899, 252. The morphology of *Mentha piperita* and other species of *Mentha* are discussed by Eriksson in *B. P. G.,* xviii, p. 244. The herb, both in the recent and in the dried state, has a peculiar, penetrating, grateful odor. Peppermint is quite frequently contaminated with spearmint and in one instance the leaves of belladonna were found. The latter, while no doubt accidental, shows the necessity for the examination of crude drugs generally. (*Pharm. Prax.,* iv, p. 38.) There is sometimes difficulty in distinguishing between the leaves of peppermint and those of spearmint. The outstanding physical differences between these are the following: The petioles of peppermint are 4 to 12 mm. in length whereas those of spearmint are less than 5 mm. in length. The blades of peppermint are of a darker shade of green than those of spearmint. Moreover, upon masticating the leaves of peppermint and drawing in the breath, a cooling sensation is experienced, no such sensation being evidenced with spearmint leaves. According to Joseph Schrenk, crystals can always be found in the glandular hairs of the peppermint, but are absent in those of the spearmint. The crystals are doubly refractive, and so transparent that sometimes a polariscope is necessary for their easy detection. These crystals have been thought to be menthol, but they seem not to dissolve in alcohol, and are probably hesperidin.

The medicinal properties depend on a volatile oil, of which from 1 to 1.25 per cent. can be obtained from the herb. The leaves are said to contain a little tannic acid.

Uses.—Peppermint is an aromatic stimulant, much used to allay *nausea,* relieve *spasmodic pains of the stomach and bowels,* expel *flatus,* or cover the taste or qualify the nauseating or griping effects of other medicines. (See *Oleum Menthæ Piperitæ.*)

Dose, one drachm (3.9 Gm.).

Off. Prep.—Spiritus Menthæ Piperitæ, *U. S.*

MENTHA VIRIDIS. U. S.

SPEARMINT Menth. Vir.

"Spearmint consists of the dried leaves and tops of *Mentha spicata* Linné (Fam. *Labiatæ*). Spearmint contains not more than 2 per cent. of stems over 3 mm. in diameter, or other foreign organic matter." *U. S.*

Herba Menthæ Acutæ (vel Romanæ); Brown, Lamb, Garden, or Mackerel Mint; Menthe verte, *Fr. Cod.;* Menthe romaine, Baume vert, Menthe à épi, *Fr.;* Grüne Münze, Römische Minze, *G*

Spearmint, sometimes called simply *mint,* differs from *M. piperita* chiefly in having nearly sessile, oblong or ovate-lanceolate, unequally serrate leaves of a lighter green color; elongated, interrupted, narrow spikes; setaceous bracts; and stamens longer than the tube of the corolla. It is a native of Europe and Asia, and naturalized in moist waste places from Nova Scotia as far south as Florida and westward to Minnesota and Kansas. It is also cultivated for domestic use and for the sake of its oil. Its flowering season is August. The drug is harvested in late summer and dried like hay. The commercial supplies are obtained chiefly from Michigan, the Carolinas and Virginia. Northern grown spearmint is the more highly esteemed.

Description and Physical Properties.—"*Unground Spearmint.*—Leaves more or less crumpled, ovate-lanceolate, unequally serrate, nearly sessile or with a petiole less than 5 mm. in length, of a bright green color and somewhat glandular-hairy on the under surface; stem, occasionally with characteristic opposite branches, distinctly quadrangular, from 1 to 3 mm. in diameter, nearly glabrous and light brown or purplish-colored; flowers arranged in opposite clusters and in more or less interrupted or crowded lanceolate, nearly acute spikes; bracts linear-lanceolate, subulate, from 7 to 10 mm. in length, subtending the flower clusters; calyx tubular, 5-toothed, glandular-punctate and somewhat pubescent near the teeth; corolla nearly white or light brown; stamens extending beyond the corolla tube; odor slightly pungent characteristic; taste aromatic, characteristic but not followed by a cooling sensation in the mouth.

"*Powdered Spearmint.*—Green; closely resembling the powder of Peppermint, except in the absence of crystals from the globular heads of the glandular hairs." *U. S.*

Spearmint was cultivated in the Convent gardens of the ninth century. It is largely used as a domestic and popular flavor in foods, chewing gum, and confectionery and is used in culinary practice for mint sauce and for flavoring green vegetables, as peas, etc. It is also the mint of mint julep fame. The plant is widely cultivated, and Schimmel and Co. present a review of its cultivation in Michigan, Indiana and New York in *Schim. Rep.,* October, 1910, p. 131. Experiments have also been conducted in Louisiana, and Phenis states the resulting oil to be of the highest grade. (*Paint, Oil, and Drug Review,* xlvi, p. 27.) Successful experiments have also been conducted in Wisconsin. (*Ibid.,* xliv, p. 18.) Mitlacher has reported that *Mentha crispa* L. can be successfully grown in Austria. (*Ph. Post,* xliv, p. 215.)

Spearmint is frequently admixed with peppermint. This is particularly noticeable in the supplies of this drug coming from Virginia and North and South Carolina which have contained from 30 to 50 per cent. of peppermint. This is probably due to carelessness. The taste and odor of spearmint are retained for some time by the dried plant. They depend on a volatile oil. (See *Oleum Menthæ Viridis.*)

Dose, one drachm (3.9 Gm.).

Off. Prep.—Spiritus Menthæ Viridis, *U. S.*

MENTHOL. U. S., Br.

MENTHOL

"An alcohol [$C_{10}H_{19}OH$] obtained from oil of peppermint or other mint oils." *U. S.* "Menthol, $C_{10}H_{20}O$, is a crystalline substance obtained by cooling the oil distilled from the fresh herb of Mentha arvensis, *DC., vars.* piperascens et glabrata, *Holmes;* and probably other species of Mentha." *Br.*

Peppermint Camphor; Camphora Menthæ; Camphre de Menthe, Mentholum, *Fr.;* Mentholum, *P. G.;* Menthol, Pfefferminzkampher, Mentha-Kampher, Pipmenthol, *G.;* Mentolo, *It.;* Mentol, *Sp.*

Menthol, or *peppermint camphor,* may be obtained from either *American, Chinese* or *Japanese oil of peppermint,* by cooling the oil to a very low temperature, when the menthol crystallizes out, often in a dense mass; the adhering oil may be separated by expression. Menthol may also be obtained by fractional distillation, and there is reason to believe that the oil of peppermint of commerce is often contaminated with the dementholized oil. American oil of peppermint is obtained from *Mentha piperita,* the Chinese oil from *M. arvensis* var. *glabrata,* and the Japanese oil from *M. arvensis* var. *piperascens.* A larger yield of menthol is obtained from Japanese or Chinese oils, and for this reason Japanese menthol is largely found in commerce. It is practically identical with American menthol, differing, however, in the character of its crystals, which occur in small prisms instead of in long needles.

Description and Physical Properties.—"Colorless, acicular crystals, having a strong, peppermint-like odor. Menthol is slightly soluble in water; very soluble in alcohol, chloroform, ether, and in petroleum benzin. It is freely soluble in glacial acetic acid, liquid petrolatum, and in fixed or volatile oils. When Menthol is triturated with about an equal weight of camphor, chloral hydrate, phenol, or thymol, the mixture liquefies.

"Menthol melts between 42° and 44° C. Its alcoholic solution is lævorotatory. Heat 2 Gm. of Menthol in an open dish on a water bath: it gradually volatilizes without leaving more than 0.05 per cent. of residue (*wax, paraffin,* or *inorganic substances*). Dissolve about 0.1 Gm. of Menthol in 1 cc. of glacial acetic acid, and add 3 drops of sulphuric acid and 1 drop of nitric acid: no green color is produced (*thymol*).

"Preserve in well-closed containers, in a cool place." *U. S.*

"Colorless acicular crystals or crystalline masses. Melting point 42° to 43° C. Odor and taste recalling peppermint; produces a sensation of warmth on the tongue and, if air is inhaled, a sensation of cold. Entirely volatilized by the heat of a water-bath. Very slightly soluble in *water,* but readily soluble in *alcohol* (90 per cent.), the solutions being neutral to *litmus.* Boiled with *sulphuric acid* diluted with half its volume of *water,* Menthol acquires an indigo-blue or ultramarine color, the acid becoming brown." *Br.*

Menthol is a stearopten. Its formula may be written $C_{10}H_{19}OH$, as it is recognized as being a saturated secondary alcohol. Chromium trioxide oxidizes menthol to *dextro-* and *lævomenthone,* $C_{10}H_{18}O$, which is the ketone corresponding. The *menthones* are liquids, with an odor resembling that of peppermint. They boil at 207° C. Distillation with zinc chloride or phosphoric anhydride changes menthol into liquid *menthene,* $C_{10}H_{18}$, boiling at 167° C. (See papers by Kremers, Urban, and Richtmann on the menthol group, *Proc. A. Ph. A.,* 1893, 185; also 1896, 200.) Menthol has been grossly adulterated with spermaceti, paraffin, etc., and, after being compressed into pencils or cones, sold as a local panacea for headache and neuralgia.

Menthol may be made synthetically by the reduction of *menthone* or of *pulegone.* There are a number of homologues of menthol which have been prepared artificially. There have been a number of isomeric menthols produced also, none of which are of medicinal importance.

For assay of preparations containing menthol when no interfering substances are present it is simply necessary to salt out with sodium chloride or shake out with petroleum ether and evaporate the latter in a desiccator. (See papers by Schaefer, *Pract. Drug.,* Aug., 1919, p. 28 and Mayer, *J. A. Ph. A.,* 1919, viii, 572.)

Uses.—According to Schwenkenbecher (*M. M. W.,* 1908, lv, p. 1495), menthol in large doses is a narcotic, paralyzing eventually both the sensory and motor systems. It cannot, however, be regarded as highly toxic, for he, himself, took 8 Gm. within a period of two hours without suffering serious symptoms. When locally applied it stimulates the nerves for the perception of cold, but depresses those for pain. It is actively antibacterial; according to McDonald, it is about twice as powerful as phenol. Menthol is used for its local anesthetic influence in various *skin diseases,* accompanied with *itching,* such as *urticaria.* Probably by virtue of the same property it is also frequently of service in *nausea* and *gastrodynia.* In *headache* and other forms of *neuralgia* the external application of menthol will frequently produce considerable degree of relief; the action in these cases is probably that of a counter-irritant rather than anesthetic. A solution containing one or two per cent. of menthol in liquid petrolatum is very widely employed for its antiseptic and anesthetic influence in inflammations of the upper respiratory tract, such as *acute coryza, pharyngitis,* or *laryngitis.* It is also occasionally employed as a gastro-intestinal antiseptic. According to S. A. Russel an ethereal solution of from 10 to 50 per cent. applied 2 or 3 times a day has a remarkable power of controlling superficial inflammations, such as *boils* or *carbuncles.* Berliner (*B. K. W.,* 1910, p. 967) and others have injected, hypodermically, its oily solution with asserted benefit in various forms of *tuberculosis.* A number of cases of dangerous asphyxiation, at least one of which ended fatally, have followed the local application of menthol in infants for the relief of *coryza.* (See Lublinski, *B. K. W.,* 1912, xlix.)

Dose, one to two grains (0.065–0.13 Gm.).

METHENAMINA. U. S. (Br.)

METHENAMINE Methenam. [Hexamethylenamina, U. S. P. IX, Hexamethylenetetramine]

"Methenamine contains not less than 99 per cent. of $(CH_2)_6N_4$." *U. S.* "Hexamine may be obtained by the interaction of ammonia with formic aldehyde. It contains not less than 98 per cent. of pure hexamethylenetetramine, $C_6H_{12}N_4$." *Br.*

Hexamina, *Br.;* Urotropine, Urotropin, Cystogen, Formin, Aminoform, Cystamine, Uritone.

The full name of this compound is hexamethylenetetramine, which was originally used by Nicolaier.

It may be made by the gradual addition of 70 parts of stronger ammonia water to 100 parts of a forty per cent. solution of formaldehyde which must be kept well cooled. The ammonia water must be added carefully in small quantities until in slight excess, which is indicated by its odor remaining after the liquid has stood several hours; then ten parts of ammonia water are added and the solution allowed to stand until crystallization is completed. The hexamethylenetetramine is purified by treatment with animal charcoal and recrystallization. The reaction is as follows:

$$6HCHO + 4NH_4OH \qquad (CH_2)_6N_4 + 10H_2O$$

Description and Physical Properties.—"Colorless, lustrous crystals, or a white, crystalline powder. It is odorless. One Gm. of Methenamine is soluble in 1.5 cc. of water, 12.5 cc. of alcohol, and in about 10 cc. of chloroform, at 25° C. At about 263° C. it sublimes without melting, partly decomposing and evolving a disagreeable odor. When brought into contact with fire, it readily ignites, burning with a smokeless flame.

"An aqueous solution of Methenamine is alkaline to litmus paper. Heat an aqueous solution of Methenamine (1 in 10) with diluted sulphuric acid: it decomposes with the liberation of formaldehyde recognized by its odor or by its darkening paper moistened with silver ammonium nitrate T.S. On the subsequent addition of an excess of solution of sodium hydroxide, ammonia is liberated.

"Ash: not more than 0.05 per cent. Add 1 cc. of alkaline mercuric potassium iodide T.S. to 10 cc. of an aqueous solution of Methenamine (1 in 20): no darker color is produced than results from the addition of the same amount of the reagent to 10 cc. of distilled water (*ammonium salts*). An aqueous solution of Methenamine (1 in 50) does not become colored or turbid when mixed with an equal volume of hydrogen sulphide T.S. (*heavy metals*). The addition of 5 drops of barium chloride T.S. to 10 cc. of an aqueous solution of Methenamine (1 in 50), acidulated with 5 drops of hydrochloric acid, produces no turbidity within one minute (*sulphate*). One Gm. of Methenamine shows no more *chloride* than corresponds to 0.2 cc. of fiftieth-normal hydrochloric acid.

"Preserve in well-closed containers.

"**Assay.**—Place about 1 Gm. of Methenamine, accurately weighed, in a beaker, add 40 cc. of normal sulphuric acid, and evaporate on a water bath (or boil gently, adding a little distilled water from time to time, if necessary) until the odor of formaldehyde is no longer perceptible. Cool, add 20 cc. of distilled water, and titrate the excess of acid with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.03504 Gm. of $(CH_2)_6N_4$." *U. S.*

"Colorless crystals or crystalline powder. Inodorous; taste at first sweetish, afterwards bitter. Soluble in 1.5 parts of *water*, and in 8 parts of *alcohol* (90 per cent.). The aqueous solution is alkaline to *litmus*. When heated to 263° C., it sublimes without fusing, and partially decomposes. When heated with *diluted sulphuric acid* formic aldehyde is evolved, and when the solution is cooled and made alkaline with *solution of sodium hydroxide* ammonia is liberated. 0.1 gramme warmed with 5 millilitres of *sulphuric acid* and 0.1 gramme of *salicylic acid* develops a carmine color. A solution of 1 gramme in *water*, mixed with 35 millilitres of *N/1 solution of sulphuric acid*, evaporated on a water-bath until the odor of formaldehyde has disappeared, requires for neutralisation not more than 7 millilitres of *N/1 solution of sodium hydroxide, solution of methyl orange* being used as indicator. No appreciable ash." *Br.*

Methenamine is slightly hydrolyzed, even by water, with the liberation of ammonia by the following reaction:

$$(CH_2)_6N_4 + 6H_2O = 4NH_3 + 6CH_2O.$$

This decomposition is prevented or diminished by the presence of alkalies and is increased by the presence of acids. Being a feeble base methenamine combines with acids to form salts. It also has the effect of decomposing salts of alkalies weaker than itself and thus liberates NH_3 from ammonium salts.

It frequently becomes necessary to test for the presence of hexamethylenetetramine in differentiation from formaldehyde. The best test for this purpose is bromine water which gives an orange precipitate when added to aqueous solutions containing even minute traces of hexamethylamine. No precipitate or reaction is produced under these conditions with formaldehyde. This test is applicable directly to urine, but not to body fluids, because of the interfering effect of the proteins therein contained.

If the bromine water test is not directly applicable the fluid is tested for formaldehyde before and after distillation with sulphuric acid. The best test for formaldehyde under such conditions is that of Rimini (*Ann. di Farm.*, 1891, xvii, 97) and is applied as follows: To 10 cc. of the fluid to be tested are added in rapid succession, agitating after each addition, the following reagents in the prescribed amounts: 3 drops of a 0.5 per cent. aqueous solution of phenylhydrazine hydrochloride, 2 drops of a 0.5 per cent. aqueous solution of sodium nitroprusside and 3 drops (or a slight excess) of a 15 per cent. aqueous solution of sodium hydroxide. In the presence of formaldehyde even in amounts as small as 1 in 1,000,000, a fugitive green or blue color is produced which quickly changes to yellow and finally to yellowish-red. In the absence of formaldehyde no shade of green or blue is observed when the sodium hydroxide is added.

Methenamine is physically incompatible with lithium benzoate and similar salts, liquefaction occurring. With acetylsalicylic acid and with antipyrine chemical decomposition results. It should not be dispensed in capsule form because of the possible liberation of formaldehyde which would render the capsules insoluble and impervious to the digestive fluids.

Uses.—Locally methenamine is mildly irritant and feebly antiseptic. It is absorbed rapidly from the alimentary tract and circulates in the blood unchanged. Although the greater part is eliminated through the kidneys it has been detected in practically every secretion of the body. After it has passed through the kidney if the urine be, as it normally is, acid in reaction, the methenamine is slowly broken up with the liberation of formaldehyde. The rapidity of its decomposition appears to be in direct proportion to the degree of acidity and there is strong evidence that when the urine is alkaline the drug remains unchanged in the bladder.

Methenamine was originally introduced into medicine as a solvent for uric acid but Haskins (*A. I. M.*, December, 1915) has shown that although the solubility of uric acid in water is greatly increased by the presence of methenamine, the administration of 2 Gm. (30 grains) by mouth does not appreciably augment the solvent power of the urine and that even when given in very large dose it does not increase the solvent action of the urine as greatly as alkalization. The drug has consequently passed largely out of vogue as a uric acid solvent and is to-day used almost exclusively for its antiseptic action, especially in the urinary tract, as in *cystitis* and *pyelitis*. As its antiseptic effect is due chiefly to the decomposition of the salt and liberation of formaldehyde and as this decomposition does not take place in the urine except in the presence of an acid reaction, it is manifest that in those types of cystitis where the urine is alkaline it will be of little service unless this excretion can be rendered acid. On the other hand, in those cases of bladder infection by organisms which do not lead to ammoniacal fermentation of the urine, it is one of the most efficient antiseptics we possess. It has also been used to kill typhoid bacilli in the urine in cases of *typhoid fever*, especially during the convalescent stage. It has been recommended for the purpose of preventing infection of the kidney in *scarlet fever* and other infectious diseases but its mode of action in these conditions is not evident.

In 1908 Crowe (*A. I. P. T.*, 1908, xviii, p. 315) demonstrated the appearance of methenamine in the bile and reported three cases of *cholecystitis* in which the bile became practically sterile after its administration. Although Hanzlik (*J. A. M. A.*, 1914, lxii, p. 295) disputes these conclusions and asserts that on account of the alkalinity of the bile the drug cannot act as an antiseptic in the gall bladder, there is considerable evidence as to its value as a preventative against *gall-stones* and curative of various infections of the bile passages. Miller, in 1911, used it with good results in the treatment of *acute coryza*, and Eisenberg (*J. A. M. A.*, 1912, June 29), in *acute bronchitis*. Despite the theoretical objections which have been urged against this treatment the clinical evidence of its value in those various respiratory infections commonly called *colds*, is too strong to be denied. In our experience, if used within twenty-four hours after the onset of symptoms, in a considerable proportion of cases the infection can be completely aborted. It has also been suggested for its influence in preventing the growth of germs in the cerebro-spinal fluid, as in *meningitis* and *poliomyelitis*, but its usefulness in these conditions has not been established.

If, as seems at present probable, the value of methenamine depends upon the liberation of formaldehyde, it is evident that it must be used in sufficiently large doses to form an antiseptic quantity of this reagent. Hinman (*J. A. M. A.*, 1913, lxi, p. 1601), as the result of experimental studies, reaches the conclusion that on account of the fact that some of the drug escapes decomposition, at least forty-five grains (3 Gm.) a day are required in *cystitis*.

When given in very large doses it often causes violent inflammation of the urinary tract evidenced by albuminuria, hematuria and tenesmus. Generally the inflammatory condition is limited to the bladder but Abt (*Med. Clinic of Chicago*, 1917, ii, 904) has seen fatal nephritis due to its over-use. As these irritations are due to an excess of formaldehyde liberated the treatment consists in the administration of sufficient doses of bicarbonate or citrate of soda to keep the urine alkaline and of large amounts of water to dilute it.

Not only are there a large number of compounds of methenamine upon the market, but the official drug is sold under an almost innumerable number of trade names. The compounds of hexamethylenetetramine are considered in Part II.

An interesting and novel use of hexamethylenamine is afforded by its ready inflammability, and the fact that it burns with a smokeless flame. In the absence of a Bunsen burner or an alcohol lamp, a five grain tablet of methenamine placed upon a metal or other non-inflammable surface and ignited will develop enough heat to boil a test tube full of liquid, to sterilize a hypodermic needle or to make a test for albumen in urine.

Dose, five to twenty grains (0.32–1.3 Gm.).

METHYLIS SALICYLAS. U. S. (Br.)

METHYL SALICYLATE Methyl. Salicyl.
Oil of Gaultheria, Oil of Wintergreen, Oil of Betula
Oil of Sweet Birch, Oil of Teaberry]

"Methyl Salicylate is produced synthetically or is obtained by distillation from the leaves of *Gaultheria procumbens* Linné (Fam. *Ericaceæ*) or from the bark of *Betula lenta* Linné (Fam. *Betulaceæ*). The label must indicate whether the Methyl Salicylate has been made synthetically or distilled from either of the above mentioned plants. It contains not less than 98 per cent. of $C_6H_4(OH)CO_2CH_3$." *U. S.* "Methyl Salicylate is the methyl ester of salicylic acid. It may be obtained by the interaction of methyl alcohol and salicylic acid. It contains not less than 98 per cent. of pure methyl salicylate, $CH_3C_7H_5O_3$." *Br.*

Methyl Salicylas, *Br.;* Synthetic Oil of Wintergreen; Salicylate de Méthyle, *Fr.;* Methylsalicylat, Künstliches Wintergrünol, *G.*

Methyl Salicylate occurs in a number of volatile oils (see *Oleum Gaultheriæ*). It is also manufactured on a large scale from synthetic salicylic acid. Although there was, at one time, a widespread belief that synthetic methyl salicylate was more toxic than the natural oil, it is without scientific support (see *J. A. M. A.*, 1913, lxi, 979). Because of the established identity in action and because of the impossibility in distinguishing between the synthetic and natural oil, the U. S. Pharmacopœia at the ninth revision dismissed the title of "Oil of Wintergreen." Many investigators have attempted to devise tests for differentiating the oils of wintergreen and birch and methyl salicylate, but as soon as a reaction is proposed and described, its unreliability is quickly proved by other investigators. Vanillin and alcohol, heliotropin and sulphuric acid, chloral hydrate and sulphuric acid are among the reagents which have been proposed, none of which seem to be infallible with mixtures, although they do show decided differences with the pure oils. References to some of the articles on this subject are as follows: *Schim. Rep.*, 1914, Apr., p. 99; *J. A. Ph. A.*, 1914, p. 1658; Hurley (*Pract. Drug.*, 1921, xxxix, 121) and LaWall (*A. J. P.*, 1920, xcii, 891).

Methyl salicylate may be made by distilling salicylic acid or a salicylate, with methyl alcohol and strong sulphuric acid. The reaction is as follows:

$$C_6H_4OHCOOH + CH_3OH = C_6H_4OHCOOCH_3 + H_2O.$$

The sulphuric acid plays no part in the reaction except to serve as a dehydrating agent. The following process was devised by G. M. Beringer (*A. J. P.*, 1887, p. 8). Dissolve half an ounce of salicylic acid in two fluidounces of absolute methyl alcohol, then gradually add one fluidounce of sulphuric acid; warm gently for twenty-four hours, then distil from a retort into which a current of steam is introduced. The distillate is to be well washed, and separated by decantation. The odor improves with age. Methyl salicylate has been found in a great number of plants. (See *A. J. P.*, 1898, 412; *Ph. Rev.*, 1898, 130; *Schim. Rep.*, 1898, 45; 1899, 46.)

Description and Physical Properties.—"A colorless, yellowish, or reddish liquid, having the characteristic odor and taste of gaultheria. Methyl Salicylate is slightly soluble in water, but is miscible with alcohol and with glacial acetic acid. It is soluble in about 7 volumes of 70 per cent. alcohol at 25° C. with not more than a slight cloudiness.

"Specific gravity at 25° C.; synthetic, 1.180 to 1.185; from gaultheria or betula, 1.176 to 1.182. It boils between 219° and 224° C. Synthetic Methyl Salicylate, or that from betula, is optically inactive. Methyl Salicylate from gaultheria is slightly lævorotatory, not exceeding $-1.5°$ in a 100 mm. tube at 25° C. A deep violet color is produced by shaking a drop of Methyl Salicylate with about 5 cc. of distilled water and adding a drop of ferric chloride T.S.

"An alcoholic solution of Methyl Salicylate is neutral or slightly acid to moistened litmus paper. Add 10 cc. of potassium hydroxide T.S. to 1 cc. of Methyl Salicylate contained in a capacious test tube, and agitate the mixture: a clear, or slightly cloudy, and colorless or faintly yellowish solution results without the separation of any oily drops either on the surface or at the bottom of the liquid (*other volatile oils or petroleum products*). Methyl Salicylate meets the requirements of the test for *heavy metals in volatile oils.*

"Preserve in amber colored bottles, well stoppered in a cool place." *U. S.*

"A colorless liquid. Characteristic, aromatic odor; taste sweetish, warm, aromatic. Slightly soluble in *water;* readily soluble in *alcohol* (90 per cent.), in *glacial acetic acid,* and in *carbon disulphide.* Specific gravity 1.185 to 1.192. Boiling point from 219° to 221° C. Optically inactive. The solution in *alcohol* (90 per cent.) is neutral or faintly acid to *litmus.* The aqueous solution is colored violet by the addition of a drop of *T. Sol. of ferric chloride.* Contains not less than 98 per cent. of the *ester* methyl salicylate, $CH_3C_7H_5O_3$." *Br.*

"**Assay.**—Place about 2 cc. of Methyl Salicylate, accurately weighed, in a tared flask, add 50 cc. of half-normal alcoholic potassium hydroxide, connect the flask with a reflux condenser, and heat the mixture on a water bath for two hours. Add a few drops of phenolphthalein T.S., and titrate the excess of alkali with half-normal hydrochloric acid. Each cc. of half-normal alcoholic potassium hydroxide corresponds to 0.07605 Gm. of $C_6H_4(OH)CO_2CH_3$.

"Preserve in well-stoppered, amber-colored bottles, in a cool place." *U. S.*

Uses.—Methyl salicylate is used chiefly in the treatment of various forms of *rheumatism* in which other preparations of salicylic acid are of service. It has the advantage over the inorganic salicylates of being less unpleasant to the taste, but in our experience is somewhat more prone to cause digestive disturbances and according to Hanzlik and Wetzel (*J. P. Ex. T.*, 1919, xiv, p. 43) is less perfectly absorbed. Because of its volatility it is capable of being absorbed through the skin and is frequently applied externally for its systemic effect. For this purpose it may be mixed with equal parts of lard and a drachm of the mixture spread over a surface as big as the palm of the hand and covered with an impermeable dressing to prevent evaporation. It is also employed for its counter-irritant action in various liniments. As a flavoring agent two minims may be used for each fluidounce.

Internally it is best administered in emulsion, although sometimes taken by dropping into a teaspoonful of sugar. The custom of giving it in capsules is to be deprecated as it is much more likely to irritate the stomach under these circumstances.

For cases of methyl salicylate poisoning see Rosenbloom and Johnston, *J. A. M. A.*, 1919, lxxii, 22.

Dose, from five to twenty minims (0.3–1.2 cc.).

Off. Prep.—Inunctum Mentholis Compositum, *N. F.;* Liquor Antisepticus, *N. F.;* Liquor Antisepticus Alkalinus, *N. F.;* Liquor Ferri Salicylatis, *N. F.;* Liquor Pepsini Antisepticus, *N. F.;* Nebula Aromatica, *N. F.;* Nebula Mentholis Composita, *N. F.;* Petroxolinum Methylis Salicylatis, *N. F.;* Odontalgicum, *N. F.*

METHYLTHIONINÆ CHLORIDUM. U. S.

METHYLTHIONINE CHLORIDE Methylthionin. Chlor. [Methylene Blue]

"Tetramethylthionine chloride [$C_{16}H_{18}N_3ClS.3H_2O$]." *U. S.*

Methylthionine Hydrochloride; Medicinal Methylene Blue; Methylenium Ceruleum, *Fr. Cod.;* Chlorhydrate de Tetraméthylthionine, *Fr.;* Tetramethylthioninchlorid, Methylen Blau, *G.*

This synthetic dye color belongs to the class of *thiazines* or dyestuffs in which two benzene nuclei are united by a nitrogen atom and a sulphur atom. *Methylene blue* was discovered by Caro in 1876, and was made by the oxidation of *p*-amido-dimethyl aniline with ferric chloride in the presence of hydrogen sulphide. Both the hydrochloride of the base and the zinc chloride double salt of the same are known by the name of methylene blue. It is only the former that is used in medicine and constitutes the official salt. Methylene Blue must not be confounded with *methyl blue,* a dark blue powder which is used as an antiseptic; the latter is sodium triphenyl-pararosaniline-sulphonate.

The dye known as methylene blue differs in composition from the medicine being the chloride of zinc and methylthionine; it is much more poisonous.

Description and Physical Properties.—"Dark green crystals or a crystalline powder, having a bronze-like luster. It is odorless, and is stable in the air. Methylthionine Chloride is freely soluble in water and in alcohol; soluble in chloroform, the solutions having a deep blue color.

"The addition of hydrochloric acid to its aqueous solution changes the color to a lighter shade of blue. The addition of sodium hydroxide T.S. changes the color to a purplish shade, and, if added in excess, produces, on standing, a precipitate having a dull violet color. A solution of Methylthionine Chloride in diluted sulphuric acid is gradually decolorized upon the addition of zinc dust.

"Methylthionine Chloride, dried to constant weight at 110° C., loses not more than 16 per cent. (*moisture*). Ash: not more than 1 per cent. Intimately mix 0.2 Gm. of Methylthionine Chloride with about 0.5 Gm. each of powdered potassium nitrate and anhydrous sodium carbonate, and heat the mixture in a crucible until the organic matter is completely oxidized. Dissolve the cooled residue in 15 cc. of diluted sulphuric acid, and evaporate the solution over a flame until the vapors of sulphuric acid begin to evolve: the residue so obtained meets the requirements of the test for *arsenic.* Heat 0.5 Gm. of Methylthionine Chloride at a temperature below a red heat until it is completely carbonized, boil the powdered residue with 10 cc. of diluted hydrochloric acid for five minutes, filter, and wash the residue with 10 cc. of distilled water. Boil the combined filtrate and washings with 1 cc. of nitric acid, supersaturate with ammonia T.S., and filter if necessary: the liquid remains clear upon the addition of an equal volume of hydrogen sulphide T.S. (*zinc.*) Dissolve 1 Gm. of Methylthionine Chloride in 50 cc. of boiling alcohol, filter through counterbalanced filters, wash the residue on the filter with boiling alcohol until the washings cease to be colored blue, and dry it at 100° C.: the weight corresponds to not more than 1 per cent. (*dextrin*)." *U. S.*

Uses.—When taken internally methylene blue is absorbed and eliminated chiefly from the kidneys, coloring the urine blue or greenish. In therapeutic doses it produces no symptoms except occasionally some irritation of the bladder, and we know of no serious cases of poisoning with the pure article. It is a feeble antiseptic and has been used to a considerable extent in *gonorrhea, cystitis* and *pyelitis,* but its value is certainly not great. As an analgesic, it has been employed in *neuralgia, locomotor ataxia,* etc., but is inferior to other aniline derivatives. In 1891, Ehrlich and Guttmann (*B. K. W.,* xxviii), led by its power as a staining agent over the plasmodium malariæ, suggested its practical use as an antiperiodic, and its value as such is well established. In 425 cases collected by H. C. Wood, Jr. (*Trans. Phila. County Med. Soc.,* 1904), there were 85 per cent. of cures. It does not produce disturbances of the special senses or of the gastro-intestinal tract, and therefore may be preferable to quinine in aural or gastro-intestinal affections. Further, on account of its lack of action upon the kidney, it is especially valuable in those forms of *malaria* accompanied with *hematuria,* the so-called "*black water fever.*" If the statement of Iwanoff, that it especially acts upon the adult forms of plasmodium be correct, it should be especially valuable in *chronic malaria,* and experience may prove that the best treatment of this condition is the administration of full doses of quinine at intervals of seven days, with the continuous use of the methylene blue. Slack (*Atlanta Journal and Record of Medicine,* 1907) recommends the internal use of methylthionine in *carcinoma;* it seems not only to relieve the pain but also to delay the growth of the tumor. Binger (*J. Inf. D.,* 1919, xxv, 277) from a study of its effect on the meningococcus has suggested its use in *meningitis.*

Methylene blue is preferably administered in capsule. In malaria from ten to twenty grains (0.65–1.3 Gm.) may be given in the course of a day for ten days, and after this six to ten grains (0.4–0.65 Gm.) a day for two weeks. In obstinate cases a full dose of quinine may be exhibited every seventh day, the methylene blue being omitted. The staining action of methylene blue upon any portion of the body or clothing with which it may come in contact, and its color effect upon the urine, should always be explained to the patient.

Dose, two to five grains (0.13–0.32 Gm.).

MEZEREUM. N. F.

MEZEREUM [Mezereon]

"Mezereum is the dried bark from aerial portions of *Daphne Mezereum* Linné, *Daphne Gnidium* Linné, or of *Daphne Laureola* Linné (Fam. *Thymeleaceæ*). Mezereum contains not more than 2 per cent. of foreign organic matter." *N. F.*

Mezerei Cortex, *Br.* 1898; Mezereon Bark; Cortex Mezerei, Cortex Thymeleæ (vel Coccognidii), Dwarf Bay, Wild Pepper, Spurge-flax, Spurge-olive, Magell; Mézéréon, Bois gentil, *Fr.;* Lauréole, Thymelée, *Fr.;* Kellerhals, Seidelbastrinde, Kellerhalsrinde, *G.;* Mezereo, *It.;* Mecereon, *Sp.*

All the species of *Daphne* are possessed of active properties, but three only are official—*D. Mezereum, D. Laureola,* and *D. Gnidium.*

Daphne Mezereum is a very hardy, low shrub, with a branching stem, and a smooth, dark gray bark, very easily separable from the wood. The leaves spring from the ends of the branches, are deciduous, sessile, obovate-lanceolate, entire, smooth, and of a pale green color, somewhat glaucous beneath. They are preceded by the flowers, which appear very early in the spring, and sometimes bloom even amidst the snow. These are of a purple-rose color, rarely white, highly fragrant, and disposed in clusters, each consisting of two or three flowers, forming together a kind of spike at the upper part of the stem and branches. At the base of each cluster are deciduous floral leaves. The fruit is oval, shining, fleshy, of a bright red color, and contains a single round seed. Another variety produces white flowers and yellow fruit. This species of *Daphne* occurs throughout the forests of Europe, and extends in Western Asia from the Caucasus to the Altai. It is cultivated in Europe, and is occasionally found in our own gardens. *D. Mezereum* is locally naturalized from New York and Massachusetts to western Quebec and Ontario.

Daphne Gnidium.—In this species, called *garou* or *sain-bois* by the French, the leaves are linear-lanceolate, acute, entire, smooth, and irregularly but closely set upon the branches. The flowers are white, downy, odoriferous, and disposed in terminal panicled racemes. The fruit is globular, dry, at first green, but ultimately black. *D. Gnidium* grows in dry uncultivated places in the south of Europe, and flowers in June. Its bark, which in France is used indiscriminately with that of the former species, is of a deep purplish-brown color, and hairy in the younger portions. It appears to be equally as active, medicinally, as the other official species.

Besides the species above described, *Daphne Laureola,* or *spurge laurel,* is said to furnish a portion of mezereum of commerce, and is recognized by the N. F., but its product is inferior in acrimony, and consequently in medicinal activity.

The commercial supplies of mezereum come chiefly from southern France.

Properties.—The bark of the root was formerly directed, but the mezereum with which our markets are supplied is evidently the bark of the stem, and the N. F. at present very properly directs the bark, without designating the part from which it must be taken.

Description and Physical Properties.—"*Unground Mezereum.*—In flexible, tough quilled pieces or somewhat flattened strips attaining a length of 90 cm.; from 0.3 to 1 mm. in thickness; outer surface yellowish or olive-brown (*D. Mezereum*) or purplish-brown (*D. Gnidium*) or purplish-gray (*D. Laureola*), smooth, numerous lenticels giving a transversely striated appearance and occasionally with numerous, circular, brownish-black apothecia; outer corky layer easily separable from the middle bark which varies from light green to olive-brown and with more or less detached bast fibers; inner surface yellowish white; satiny lustrous, finely striate; fracture tough, fibrous, the inner bark lamellated. Odor very slight; taste at first slight, becoming gradually and increasingly pungent and acrid.

"*Structure.*—A rather thick cork composed of from 20 to 30 rows of cells, the outer being compressed and with yellowish-brown walls, and the inner more or less tubular with nearly colorless walls; a hypodermis of 3 to 5 rows of collenchymatous cells containing chloroplastids or a yellowish-green resinous substance; an inner bark consisting mostly of nearly colorless non-lignified bast-fibers occurring in loosely united groups, and a few starch-bearing medullary rays one cell in width.

"*Powdered Mezereum.*—Light grayish-brown; bast-fibers numerous, from 0.4 to 3 mm. in length and about 0.015 mm. in width, frequently uneven or irregularly bent and considerably attenuated at the ends, the walls being from 0.001 to 0.005 mm. in thickness, colorless, non-lignified and free from pores; fragments of yellowish-brown cork cells and starch-bearing medullary rays; starch grains relatively few, mostly spherical or elliptical, occasionally 2- to 4-compound, the individual grains from 0.003 to 0.15 mm. in diameter." *N. F.*

British writers state that the bark of the root is the most active. The berries and leaves of the plant are also active, and the former have sometimes proved fatal to children who have eaten them.

Vauquelin discovered a bitter glucosidal principle which has received the name of *daphnin.* Gmelin and Bär found it in the bark of *D. Mezereum,* associated with wax, an acrid resin (*mezerein*), a yellow coloring matter, a reddish-brown extractive, and uncrystallizable and fermentable sugar, a gummy matter containing nitrogen, ligneous fiber, malic acid, and several malates. Mezerein, which is easily changed into *mezereic acid,* may be considered as the substance to which the medicinal properties of the drug are due. *Daphnin* is in prismatic crystals, grouped together, colorless, transparent, brilliant, slightly soluble in cold water, very soluble in boiling water and alcohol, without odor, and of a bitter, somewhat harsh, but not acrid taste. Daphnin is isomeric with æsculin and, like it, yields, on hydrolysis, sugar and dioxycoumarin. (See Will and Jung, *A. J. P.,* 1885.) (For a method of preparing the glucoside daphnin, see *U. S. D.,* nineteenth edition, p. 781.) *Coccognin,* isolated in 1870 by Casselmann from the fruits of *D. Mezereum,* appears to be closely allied to, if not identical with, daphnin. By the dry distillation of an alcoholic extract of mezereum bark, Zwenger obtained umbelliferone.

The medicinal properties of mezereon reside in the resin.

Uses.—The recent bark applied to the skin produces inflammation followed by vesication, and has been popularly used as an epispastic, from time immemorial, in some of the southern countries of Europe; the dried bark, though less active, is possessed of a similar property and is occasionally employed in France by regular practitioners for the purpose of forming issues. It is slow in its operation, generally requiring from twenty-four to forty-eight hours to vesicate. The ointment was formerly used for maintaining the discharge from blistered surfaces, and may be applied advantageously to obstinate, ill-conditioned indolent *ulcers.* It was recognized by the U. S. 1880. (See *U. S. D.,* 19th ed., p. 781, for formula.)

Internally administered, mezereum is a stimulant capable of being directed to the skin or kidneys, and in large doses likely to excite purging, nausea, and vomiting. In overdoses it produces the fatal effects of the acrid poisons, and a case of apparently severe narcotic effects has been recorded. (*Am. J. M. S.,* xxi.) It had at one time much reputation as an alterative in *syphilis, chronic rheumatism,* etc., but is of no value as an internal remedy and is almost never administered save as an ingredient of the compound fluidextract of sarsaparilla.

Dose, ten grains (0.65 Gm.).

Off. Prep.—Fluidextractum Sarsaparillæ Compositum, *N. F.;* Fluidextractum Mezerei, *N. F.;* Linimentum Sinapis Compositum (from Fluidextract), *N. F.*

MISTURA AMMONIACI. Br.

AMMONIACUM MIXTURE

Emulsum Ammoniaci, *U. S.* 1890, Emulsion of Ammoniac; Ammoniac Mixture; Emulsio Ammoniaci, Lac Ammoniaci; Milk of Ammoniac; Mixture de Gomme ammoniaque, *Lat.;* d'ammoniaque, *Fr.;* Ammoniak-Emulsion, *G.*

"Ammoniacum, in coarse powder, 30 *grammes;* Syrup of Tolu, 60 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Triturate the Ammoniacum thoroughly with a little of the Distilled Water so as to form a thin paste; gradually add the remainder of the Distilled Water and the Syrup of Tolu, triturating until the mixture assumes a uniform milky appearance; strain through muslin." *Br.*

In this emulsion the resinous and oily constituents are suspended by means of the gum of the ammoniac, imparting a milky appearance to the preparation, which from this circumstance was formerly called *lac ammoniaci,* or *milk of ammoniac.* The greater portion of the resin subsides upon standing. This emulsion is no longer official; that of the U. S. 1890 was slightly stronger, representing 4 per cent. of ammoniac as against 3 in the British.

Dose, one-half to a fluidounce (15–30 cc.).

MISTURA AMYGDALÆ. Br.

ALMOND MIXTURE

Emulsum Amygdalæ, *U. S. IX;* Emulsion of Almond; Milk of Almond; Emulsio Amygdalæ, s. Amygdalarum, Emulsio Simplex; Milk of Almonds; Simple Emulsion; Look Album, *Fr. Cod.;* Emulsion d'Amande, Lait d'Amande, *Fr.;* Mandelemulsion, Mandelmilch, *G.;* Emulsione di mandorle dolci, Looch Bianco, *It.;* Emulsion comun, *Sp.*

"Compound Powder of Almonds, 125 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Triturate the Powder with a little of the Distilled Water so as to form a thin paste; gradually add the remainder of the Distilled Water; strain through fine muslin." *Br.*

The Emulsion of Almond of the U. S. IX was practically the same as the above. The gum arabic in these formulas is introduced not so much for its demulcent properties as to assist in the suspension of the insoluble ingredients of the almonds. The same formula will answer for the preparation of an *emulsion of bitter almonds* from bitter almond or peach kernels. The oleaginous matter of the almonds is suspended in the water by means of their albumen, gum, and sugar, forming a milky emulsion. Great care should be taken to select the almonds perfectly free from rancidity. The emulsion is not permanent and compound powder of almonds often has a taint of rancidity when kept too long. Upon standing, the oil rises like thick cream to the surface, and the separation is effected more quickly by heat, alcohol or acids, which coagulate the albumen. In warm weather the preparation is likely to become sour.

Uses.—This preparation has no medicinal value outside of its nutritive properties and pleasant flavor. It is employed as an addition to the diet, sometimes as a vehicle for more active and disagreeable drugs; and occasionally as an external demulcent. Its use for the latter purpose is to be deprecated because of the sugar in it.

Dose, one-half to one fluidounce (15–30 cc.).

MISTURA CRETÆ. U. S., Br.

CHALK MIXTURE Mist. Cret.

Mixture avec la Craie, *Fr.;* Kreidemixtur, *G.*

"Prepared Chalk, 6 Gm.; Glycerin, 10 cc.; Cinnamon Water, 40 cc.; Distilled Water, a sufficient quantity, to make 100 cc. Gradually add the glycerin to the prepared chalk, in a mortar, triturating until a smooth, uniform mixture is produced. Add the cinnamon water with trituration, transfer the mixture to a graduated vessel, and rinse the mortar with enough distilled water to make the product measure 100 cc. Mix thoroughly.

"This preparation must not be dispensed unless it has been recently prepared." *U. S.*

"Prepared Chalk, 30 *grammes;* Tragacanth, in powder, 5 *grammes;* Refined Sugar, 60 *grammes;* Cinnamon Water sufficient to produce 1000 *millilitres.* Triturate the Prepared Chalk with Tragacanth and Refined Sugar, and gradually add, with constant trituration, sufficient Cinnamon Water to produce the required volume." *Br.*

The direction that this mixture be prepared extemporaneously is a decided improvement. Unsuccessful attempts have been repeatedly made to devise a formula which would yield a permanent product, and much injury has been done through the dispensing of chalk mixture in an incipient fermentative condition. The trifling amount of glycerin present in the chalk mixture official in 1870 was totally inadequate to preserve it during the warm summer months, when it is in greatest vogue. Compound Chalk Powder is official (see *Pulvis Cretæ Compositus*); it will keep indefinitely, and, besides being itself a valuable addition to the materia medica, is quickly made into chalk mixture by rubbing it with the water and cinnamon water, so that there can be no excuse for not dispensing a fresh mixture.

This mixture is a convenient form for administering chalk, and is much employed as a gastric or intestinal antacid in *hyperchlorhydria* and *diarrhea.* Laudanum and kino or catechu are very often added to increase its astringency.

Dose, four fluidrachms (15 cc.), frequently repeated.

MISTURA FERRI COMPOSITA. Br.

COMPOUND IRON MIXTURE [Griffith's Mixture]

Mixture ferrugineuse de Griffith, *Fr.;* Griffithsche Eisenmixtur, *G.*

This mixture was dropped from the U. S. P. IX; but is included in the N. F. (See Part III.)

"Ferrous Sulphate, in powder, 6 *grammes;* Potassium Carbonate, 8 *grammes;* Myrrh, 15 *grammes;* Gum Acacia, in powder, 15 *grammes;* Glucose, 15 *grammes;* Spirit of Nutmeg, 10 *millilitres;* Rose Water, sufficient to produce 1000 *millilitres.* Powder the Myrrh; add the Potassium Carbonate, Glucose, and Gum Acacia; triturate the mixture with a small quantity of the Rose Water so as to form a thin paste; gradually add more Rose Water and the Spirit of Nutmeg; continue the trituration and further addition of Rose Water until one thousand *millilitres* of liquid are produced; add the Ferrous Sulphate and shake until dissolved." *Br.*

This is very nearly the same as the celebrated tonic or *antihectic myrrh mixture* of Griffith. The ferrous sulphate is decomposed by the potassium carbonate, with the production of ferrous carbonate and potassium sulphate, while the excess of the alkaline carbonate forms an emulsion-like mixture with the myrrh. The mixture is green in color. It easily decomposes with the production of a red or brown color due to oxidation of the iron. The official solution may, however, be kept for some time without change, if the vessel in which it is contained be well closed, but the best plan is to prepare it extemporaneously. The sugar contained in it helps somewhat to retard the oxidation of the ferrous salt. The finest pieces of myrrh in lump should be selected for the preparation of this mixture.

This mixture is used in *anemia,* especially when attended with derangement of the menstrual function. It has been also employed in the hectic fever of *phthisis.* It is contra-indicated by the existence of inflammation of the gastric mucous membrane.

Dose, from one-half to two fluidounces (15–60 cc.) two or three times a day.

MISTURA GLYCYRRHIZÆ COMPOSITA. U. S.

COMPOUND MIXTURE OF GLYCYRRHIZA Mist. Glycyrrh. Co. [Brown Mixture]

Mistura Fusca; Mixture de Réglisse, *Fr.;* Zusammengesetzte Lakritzenmixtur, *G.*

"Fluidextract of Glycyrrhiza, 120.00 cc.; Antimony and Potassium Tartrate, 0.24 Gm.; Camphorated Tincture of Opium, 120.00 cc.; Spirit of Nitrous Ether, 30.00 cc.; Glycerin, 120.00 cc.; *Water,* a sufficient quantity, to make 1000 cc.

"Dilute the fluidextract with the glycerin and 500 cc. of water, add the antimony and potassium tartrate, dissolved in 12 cc. of hot water, then the other ingredients, and enough water to make the product measure 1000 cc." *U. S.*

The spirit of nitrous ether is probably useful by somewhat retarding decomposition. It has been suggested many times that this preparation be filtered and dispensed clear but the revisers of the Pharmacopœia have not considered it of sufficient importance to change the well-known appearance of the mixture and there are no advantages in making a *mixture* transparent. (See *A. J. P.*, 1892, 563; *M. R.*, 1910, 253.)

Uses.—The compound mixture of glycyrrhiza is used very frequently as a vehicle, especially in conjunction with the ammonium salts in the early stages of acute bronchitis. Its use in such manner, however, is not to be encouraged because of the presence of the antimony and opium. While the dose of the latter ingredients is so small that in a teaspoonful there will scarcely be sufficient to exercise any perceptible effect in the adult, yet their exhibition in unsuitable cases is certainly unwise. In large dose it acts as a nauseating expectorant and is sometimes given, especially in children, for its active effects in *bronchitis*. In our opinion, however, the combination is not a very happy one for this purpose.

Dose, from two to four fluidrachms (8–15 cc.) for an adult; one fluidrachm (3.75 cc.) for a child eight years old. It should be well shaken when administered.

MISTURA GUAIACI. Br.

GUAIACUM MIXTURE

Emulsio Resinæ Guaiaci; Mixture de Résine de Gayac, ait de Gayac, *Fr.;* Guajak-Emulsion, Guajakharzmixtur, *G.*

"Guaiacum Resin, 25 *grammes;* Refined Sugar, 25 *grammes;* Tragacanth, in powder, 5 *grammes;* Cinnamon Water, sufficient to produce 1000 *millilitres.* Triturate the Guaiacum Resin with the Refined Sugar and the Tragacanth; add gradually, with constant trituration, sufficient Cinnamon Water to produce the required volume." *Br.*

For the changes of color which the Guaiac in this mixture undergoes, and which it produces in other substances, see *Guaiaci Resina,* p. 539. A similar preparation under this title is official in the N. F. (See Part III).

Dose, one-half to two fluidounces (15–60 cc.), repeated two or three times a day, or more frequently.

MISTURA OLEI RICINI. Br.

CASTOR OIL MIXTURE

Emulsion of Castor Oil; Emulsion d'Huile de Ricin, *Fr.;* Ricinusoelmixtur, *G.*

"Castor Oil, 375 *millilitres;* Gum Acacia, in powder, 100 *grammes;* Orange-flower water of commerce, undiluted, 150 *millilitres;* Cinnamon Water, sufficient to produce 1000 *millilitres.* Triturate the Castor Oil with the Gum Acacia in a dry mortar; add, in one portion, two hundred *millilitres* of Cinnamon Water, and continue the trituration until the oil is completely emulsified; then, with constant trituration, add the orange-flower water and sufficient Cinnamon Water to produce the required volume." *Br.*

Under the title *Emulsum Olei Ricini* a similar preparation is official in the N. F. (See Part III.)

Dose, from one-half to two fluidounces (15–60 cc.).

MISTURA SENNÆ COMPOSITA. Br.

COMPOUND MIXTURE OF SENNA

Black Draught; Mixture de Séné composée, *Fr.;* Zusammengesetzte Senna-Aufguss, Zusammengesetzte Sennamixtur, *G.*

"Magnesium Sulphate, 250 *grammes;* Liquid Extract of Liquorice, 50 *millilitres;* Compound Tincture of Cardamoms, 100 *millilitres;* Aromatic Spirit of Ammonia, 50 *millilitres;* Infusion of Senna, sufficient to produce 1000 *millilitres.* Dissolve the Magnesium Sulphate in five hundred *millilitres* of the Infusion of Senna; add the mixed Liquid Extract of Liquorice, Compound Tincture of Cardamoms, and Aromatic Spirit of Ammonia, and sufficient infusion of Senna to produce the required volume." *Br.*

This is a form of Compound Infusion of Senna, called commonly *black draught,* which term should never be used, as death has occurred through misreading prescriptions and dispensing *"black drop"* or vinegar of opium. The Compound Mixture of Senna is an active, but rather unpleasant, cathartic.

Dose, from one to two fluidounces (30–60 cc.).

MISTURÆ

MIXTURES

Mixtures, *Fr.;* Mixturen, *G.;* Mixtura, *Sp.*

This term should be restricted, in the language of pharmacy, to those preparations in which insoluble substances, usually solid, are suspended in aqueous fluids, by the intervention of gum arabic, sugar, yolk of egg, or other viscid matter. When the suspended substance is of an oleaginous nature, the preparation is preferably called an *emulsion,* and the U. S. Pharmacopœia has recognized these as a special class. (See *Emulsa.*) The object of mixtures is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines, and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of uniform and perfect mixtures. As a rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the suspending medium, before the aqueous vehicle is added. In Great Britain, and to some extent in this country, the term mixture is used indiscriminately for aqueous medicinal liquids having more than one ingredient, and for aqueous liquids which cannot be easily classified. Many of such liquids are perfectly transparent and should be in the class appropriate to each.

A study of the principles of colloid chemistry has been brought to bear upon the subject of pharmaceutical mixtures and their preparation, with great advantage (see *Emulsa*).

MITCHELLA. N. F.

MITCHELLA Mitchel. [Squaw Vine]

"Mitchella is the dried plant of *Mitchella repens* Linné (Fam. *Rubiaceæ*). Mitchella contains not more than 5 per cent. of foreign organic matter." *N. F.*

Squaw Vine; Twin Berry; Squaw Berry; Partridge Berry; Checkerberry; Winter Clover; (*Fam.* Rubiaceæ.)

This beautiful little trailing, evergreen herb is characterized by its creeping habit, its round ovate opposite leaves which are usually variegated with whitish lines, and which remain green through the winter. The dimorphic flowers occur in pairs and are white and fragrant, but less conspicuous than the scarlet, berry-like, edible fruit which remains on the vine through the winter. The plant is native to North America being found in coniferous woods from Nova Scotia to Minnesota, south to Florida and Mexico. Abundant supplies of this drug are collected in New Hampshire.

Description and Physical Properties.—"*Unground Mitchella.*—In loosely matted masses consisting of much branched rhizomes with their fine roots together with the stems and leaves; rhizomes light yellowish to dark brown; filiform, with slender fibrous roots; stems quadrangular or flattened, light green with surface finely striated, bearing opposite leaves; leaves green, coriaceous, opposite, rounded ovate, entire up to about 2 cm. in length and with a short petiole, upper surface smooth, dark green with prominent mid-rib and veins, lower surface smooth, light and somewhat shiny. Odor faint; taste slightly bitter.

"*Powdered Mitchella.*—Light grayish-green; numerous raphides of calcium oxalate from 0.020 to 0.055 mm. in length; greenish fragments of epidermal cells with broadly elliptical stomata the latter from 0.020 to 0.027 mm. in length associated with chlorenchyma cells, some of the latter containing a yellowish amorphous content; tracheæ with spiral or reticulate markings; fragments composed of cortical parenchyma some of the cells containing raphides of calcium oxalate; starch grains, mostly simple, spheroidal or ellipsoidal and up to about 0.010 mm. in diameter." *N. F.*

E. Breneiser (*A. J. P.*, 1887, 228) found it to contain some resin, wax, mucilage, dextrin, and what appeared to be a saponin. Mitchella was employed, in decoction, by the Indian squaws, to facilitate parturition. It has been esteemed to be diuretic, tonic, and alterative like the pipsissewa, for which it is often substituted. It is used in *dysmenorrhea* and in irritation of the bladder but is of very questionable value.

Dose, from thirty to sixty grains (2–4 Gm.).

Off. Prep.—Fluidextractum Mitchellæ, *N. F.;* Elixir Aletridis Compositum, *N. F.;* Elixir Heloniadis Compositum, *N. F.*

MORPHINA

MORPHINE

"An alkaloid [$C_{17}H_{19}O_3N + H_2O = 303.18$] obtained from opium." *U. S. IX.*

Morphia, *U. S.* 1870; Morphinum, Morphium; Morphine, *Fr. Cod.;* Morphin, *G.;* Morfina, *It.*, *Sp.*

Although the base morphine is no longer official, for convenience the chemical and therapeutic properties are considered under this title and the various salts under their separate official names.

Various processes for preparing morphine have been employed. In the older processes the morphine was extracted from opium by maceration with water (either pure or acidulated), then precipitated by ammonia, and the crystals afterwards purified by the agency of alcohol, or by repeated solution in a diluted acid and precipitation. Sertürner, the discoverer of morphine, made an infusion of opium in distilled water, precipitated the morphine by ammonia in excess, dissolved the precipitate in diluted sulphuric acid, precipitated anew by ammonia, and purified by solution in boiling alcohol, and crystallization. In evaporating aqueous solutions containing morphine a temperature of 40° C. should not be exceeded.

Morphine is now produced by making opium into a thin paste with calcium chloride solution which converts the alkaloids into hydrochlorides and holds back the meconic and other acids of the drug as calcium salt. Water is then used for extraction, sodium sulphite being employed to prevent oxidation. A concentrated solution of sodium acetate is then added which precipitates narcotine and papaverine. To the filtrate a small amount of alcohol is added and the morphine then precipitated by the careful addition of ammonium chloride and slaked lime. The filtrate after the precipitation and removal of the morphine is shaken out with benzene or chloroform to recover codeine. The morphine is subsequently purified by solution in hydrochloric acid and reprecipitation.

Properties.—Morphine crystallizes from alcohol in the form of small, colorless, shining crystals. It was officially described as follows: "Colorless or white, shining, rhombic prisms, in fine needles, or as a crystalline powder; odorless; permanent in the air. One Gm. of Morphine dissolves in 3340 mils of water, 210 mils of alcohol, 1220 mils of chloroform, 6250 mils of ether, and in 100 mils of lime water, at 25° C.; also in 1075 mils of boiling water and 98 mils of boiling alcohol; insoluble in benzene. A saturated aqueous solution of Morphine is alkaline to litmus. One mil of sulphuric acid added to about 0.05 Gm. of Morphine produces either no color or at most only a red or yellow tint; on heating, a brown color is developed. Sulphuric acid containing 0.005 Gm. selenous acid in each mil gives with Morphine a blue color, changing to green and then to brown. (Codeine yields a green color, changing to blue, and afterwards to grass-green; narcotine gives a green color, changing to brown and then to cherry-red.) Nitric acid produces with Morphine an orange-red color fading to yellow. Sulphuric acid containing 0.005 Gm. of molybdic acid in each mil gives a purple color, changing to blue. Sulphuric acid containing in each mil one drop of solution of formaldehyde yields an intense, purple color. Add a few drops of ferric chloride T.S. to a neutral solution of Morphine (1 in 100), made by the careful addition of diluted sulphuric acid; a blue color is produced which is destroyed by acids, alcohol, or by heating. Morphine solutions, when mixed with an aqueous solution of potassium ferricyanide containing a drop of ferric chloride T.S., yield deep blue solutions from which, after standing, a blue precipitate separates (difference from *codeine*). Morphine loses not more than 6.5 per cent. of its weight when dried to constant weight at 100° C. (*moisture*). No weighable ash remains on incinerating 0.5 Gm. of Morphine. Dissolve about 0.1 Gm. of Morphine in 10 mils of diluted hydrochloric acid; no red coloration is produced by the addition of a few drops of ferric chloride T.S. (*meconic acid or meconates*). Warm about 0.2 Gm. of Morphine with 4 mils of potassium hydroxide T.S.; the odor of ammonia is not noticeable (*ammonium salts*). Dissolve 1 Gm. of Morphine in 10 mils of sodium hydroxide T.S., shake out the solution with three successive portions of 15, 10, and 10 mils of chloroform, passing the chloroform solutions through a small filter previously moistened with chloroform. Evaporate carefully the combined chloroform solutions to dryness on a water bath, dissolve the residue in 10 mils of fiftieth-normal sulphuric acid V.S., add a few drops of methyl red T.S. and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Not less than 7.5 mils of the latter is required (*foreign alkaloids*)." *U. S. IX.*

Despite the immense amount of labor which has been expended by chemists we are still uncertain as to the exact structure of the morphine molecule. It may be regarded as established that morphine is a tertiary base derivative from phenanthrene; it contains two hydroxyl groups, one being phenolic and the other a secondary alcohol, and also a methyl radical. For an excellent summary of the work that has been done on the structure of morphine see T. A. Henry, *Plant Alkaloids,* 1924, p. 266.

Heated in the open air, morphine burns with a bright flame, and at a red heat is wholly dissipated. In the products resulting from the combustion of opium or morphine this alkaloid may be detected, proving that it is partly volatilized when burned. Morphine in solution is to a considerable extent absorbed by animal charcoal, which, though it will part with most of the alkaloid to alcohol, cannot be wholly deprived of it by repeated washings with that liquid, either cold or hot. It is also adsorbed when filtered through kaolin or fuller's earth. Its solution restores the blue color of litmus paper reddened by acids, and turns the yellow of turmeric to brown. Morphine is a powerful reducing agent, acting upon silver nitrate and gold chloride even in cold solutions. In the presence of sulphuric acid morphine best exhibits its powers as a reducing agent. Among the most notable instances of deoxidation may be mentioned those of silver oxide, hydrated bismuth oxide, the acids of tin, tungsten, vanadium, titanium, and molybdenum. With the acids morphine forms salts, which are generally soluble, and are decomposed by the alkalies. It is dissolved also by the fixed and volatile oils. The solutions of potassium and sodium hydroxides also dissolve morphine, which is precipitated slowly from them on exposure to the air, in consequence of the absorption of carbon dioxide. Solution of ammonia has to a certain extent the same solvent power, and hence the necessity, in precipitating morphine by this alkali, not to employ it in great excess. Solution of iodine with potassium iodide precipitates the salts of morphine in aqueous solution.

With chlorine water morphine and its salts assume an orange color, and the same effect is produced on them by solution of chlorinated soda. By the contact of nitric acid they assume a blood red color, which ultimately changes to yellow, and this is one of the tests for morphine; but, as the same change of color is produced with brucine, it cannot be relied on in the absenec of other evidence. Nitric acid also produces a red color with oil of cloves, but in this case the red does not change to yellow. For other identifying tests which have been used to detect morphine, see *U. S. D.,* xx, p. 703, also papers by Lantenschlaeger (*D. C.,* 1919, lxiii, p. 352), Palet (*Anales Soc. Quim. Argentina,* through *Chem. Abst.,* 1919, xiii, p. 216) and *J. Soc. Chem. Ind.,* 1919, xxxviii, 438a.

A delicate reaction for morphine has been reported by T. H. Oliver, which is sensitive to 0.00002 Gm. morphine. It is as follows: To the solution of the suspected substance, add a few cc. of hydrogen dioxide solution and a few drops of strong ammonia water. Then stir the solution with a piece of copper wire, whereupon the previously colorless solution becomes of a deep port wine color in the presence of morphine. Codeine and dionine do not give the reaction. (*J. A. M. A.,* 1914, 63, p. 513.)

Morphine and its salts assume a fine blue color with ferric chloride; at least this is true of the alkaloid, its sulphate, acetate, and oxalate, and the same effect will be produced by the other salts, if previously decomposed by an alkali, but that this test should be satisfactory it is necessary to operate on morphine either in powder or in concentrated solution.

Formaldehyde reacts with both morphine and codeine to form medicinally active condensation products by the union of two molecules of the base with one molecule of the formaldehyde, with elimination of water; a methylene group, CH_2, uniting with two alkaloidal residues each of which loses an H atom. That formed from morphine is an amorphous base, difficultly soluble in water, but easily soluble in alkaline solution and in alcohol. It melts at 270° C., and forms a hydrochloride soluble in water. (*Proc. A. Ph. A.*, 1897, 702.)

Uses.—There can be no doubt that morphine is the chief narcotic principle of opium, from which, however, it differs somewhat in its mode of action. The effects of morphine are so protean that they can best be considered by taking the different functions of the body seriatim.

Nervous System.—Morphine is a cerebral depressant but a spinal stimulant. The relative predominance of one or the other of these actions depends upon the relative degree of development of the brain or spinal cord; thus in the frog it produces violent convulsions of the strychnic type, but in man the spinal symptoms are usually imperceptible and for medical purposes we may regard it as a general depressant as far as the nervous system is concerned. The primary action upon the cerebrum seems to be a diminution in the powers of perception, especially of pain, although there is often an evident lowering in the acuity of the special senses. With somewhat larger doses intellection becomes depressed and a tendency to drowsiness is manifest, and after toxic doses a deep comatose sleep may follow. When locally applied in sufficient concentration morphine lowers the functional activity of the peripheral nerve endings both motor and sensory. In this way it may, under certain conditions as shown by Wiki (*J. de P. P.*, 1913, xv, p. 848), exercise a local anesthetic action. It is, however, less active in this regard than some of the other allied alkaloids, notably ethyl-morphine or methyl-morphine (codeine). Among the other actions of morphine which are to be attributed to its influence on nerve centers is the contraction of the pupil, due to stimulation of the oculo-motor center, slowing of the pulse from stimulation of the cardio-inhibitory center, slowing of the respiration from depression of the respiratory center, and overcoming the action of nauseants from its action on the emetic center.

Cushny and Lieb (*J. P. Ex. T.*, 1915, vi, p. 450) have found that in the period of respiratory depression produced by morphine there is not the same sort of insensibility to carbon dioxide that is caused by some other respiratory depressants, and according to Macht (*J. P. Ex. T.*, 1915, vii, 339) small doses of morphine may lessen the sensitiveness of the respiratory center to carbon dioxide without reducing the normal volume of air breathed. Cohen and McGuigan (*J. P. Ex. T.*, 1924, xxxiii, 145) believe that the diminution of respiration is not due to a true depression of the respiratory center but simply to a blockage of the afferent impulses which ordinarily excite this center. These observations are obviously of considerable importance in connection with the clinical use of this remedy in dyspneic states.

The influence upon the unstriped muscles, especially upon the intestines, is so complex that its accurate analysis is still somewhat doubtful. Macht (*J. P. Ex. T.*, 1918, xi, p. 389) has shown that morphine has an exciting action upon unstriped muscle. On the other hand, it is well known that morphine, in the human being at least, lessens intestinal peristalsis—a fact which Macht in an earlier communication admitted and attributed to an action upon the central nervous system. In dogs defecation is a very frequent sequela after the administration of morphine. This, however, is probably due to the difference in dosage employed in dogs and man; Uhlmann and Abelin (*Zeit. E. P. T.*, 1920, xxi, 75) from experimental studies have found that while small doses of opium diminish intestinal peristalsis, larger quantities increase. Morphine causes, certainly in the lower animals and probably also in humans, a spasmodic contraction of the pylorus, which may perhaps explain the nausea that often follows its use.

Circulation.—The action of morphine upon the circulation is quite subsidiary to its effects upon the nervous system. In therapeutic doses the only manifestation of its effects on the part of the circulatory apparatus is slowing of the pulse, due, as mentioned above, to stimulation of the inhibitory center, and flushing of the skin which appears to be the result of a special action on the cutaneous blood vessels. After large doses the blood pressure is generally somewhat lowered, probably from the combined weakening of the heart and vasomotor system.

Nutrition.—Morphine affects the nutrition both through its action upon the digestive processes and through a direct influence on the bodily chemistry. It appears to lessen all the digestive secretions including salivary, gastric, and enteric, also to diminish the peristaltic movements. The direct influence of morphine upon metabolism is not clearly understood, but there is reason to believe that it has some such action.

Elimination.—A large part of the morphine is detoxicated in the body passing out as a dioxymorphine. Some of it, however, is eliminated unchanged, more through the intestinal glands than the kidneys.

Clinical Uses.—Morphine may be used in medicine to fulfil any of seven indications: (1) In its power to relieve *pain* morphine is without rival. Because, however, of its unpleasant action upon the digestive organs and the ever-present danger of formation of the habit, it should be reserved for the more severe degrees of suffering, such as in *gall-stone* or *renal colic*, or when other analgesics have failed. In this connection it should be noted that the analgesic action of morphine is greatly enhanced by combining it with even relatively feeble synergists, such as the coal tar series or scopolamine, and by recourse to this principle of combination the physician is often able to assuage the suffering with comparatively small doses of the alkaloid. (2) As a hypnotic morphine is useful, especially when the *insomnia* is due to suffering. In the purely nervous types of sleeplessness it is less valuable than the aliphatic narcotics, but is often of service as an adjuvant. (3) As a sedative to the respiratory center it is a remedy of much value in *asthma* and certain types of *cough,* such as *whooping cough.* In true *bronchitis,* however, it must be used with circumspection. In the acute stage or where the mucous membranes are dry, it often does great harm by a further checking of the bronchial secretions; on the other hand, when the secretions are very profuse it may so benumb the respiratory center as to stop their expectoration and thereby lead to a dangerous retention of fluid in the chest. (4) In intestinal conditions it is used for its influence both on secretion and peristalsis. For the latter action it is of much service in serous *diarrheas,* but when the diarrhea is due to irritation of the intestinal tract it is generally to be avoided, as it defeats nature's purpose to get rid of the irritant. For its influence upon the muscular movements of the bowel it is useful in various forms of intestinal spasm, such as *lead colic,* and also to keep the bowels at rest in certain types of *peritonitis* and other inflammatory conditions. Whole opium is usually preferred to morphine when an action upon the intestines is desired. (5) For the purpose of aiding in the production of diaphoresis it is used, especially in the form of Dover's powder, in the early stages of *colds,* in *rheumatism, influenza,* etc. (6) To allay *vomiting,* especially of reflex origin. (7) By its calmative effect it protects the system against exhaustion in debilitated conditions, as certain forms of *typhoid fever.* For the same purpose it is also a very valuable drug in the treatment of *internal hemorrhage.*

In cases where it is desired to make a profound impression upon the general system, morphine should be given hypodermically. The dose varies enormously, according to the susceptibility of the patient and the purpose for which it is used. In a general way the dose of the morphine salts, by mouth, may be given as from one-eighth to one-half grain (0.008–0.032 Gm.), and one-twelfth to one-fourth grain (0.005–0.016 Gm.) hypodermically.

In consequence of its insolubility in water, morphine in its pure state is less convenient than its salts, which are therefore always preferred. The acetate, sulphate, and hydrochloride, which have been employed, act precisely alike therapeutically, and differ from opium chiefly in being less disposed to constipate the bowels. They are also somewhat less likely to cause disagreeable after-effects than is opium, but the deodorized tincture is certainly preferable to them for many purposes. They are further adapted for hypodermic use. Oleic acid has also been proposed as a vehicle for morphine externally used, as it dissolves both the alkaloid and its salts perfectly in considerable proportion. A liniment of oleate of morphine has been proposed, consisting of 300 parts of oleic acid and 1 part of morphine scented with a little oil of bergamot.

As the proportion of acid necessary to neutralize morphine is very small, the dose of the alkaloid is practically the same as that of its salts.

Dose, one-fifth of a grain (0.012 Gm.), equivalent to a grain of powdered opium.

MORPHINÆ ACETAS. Br.

MORPHINE ACETATE

"Morphine Acetate, $C_{17}H_{19}NO_3,C_2H_4O_2,3H_2O$, is the acetate of an alkaloid, morphine, obtained from opium." *Br.*

Morphiæ Acetas, *Br.* 1867, *U. S.* 1870; Acetate of Morphia; Morphinum Aceticum; Acetas Morphicus; Acétate de Morphine, *Fr.;* Essigsaures Morphium, Morphinacetat, *G.*

No process for this salt is official; that of the U. S., 1870, may be found in the *U. S. D.,* 20th ed., p. 706.

Properties.—It is officially described in the British Pharmacopœia as "a white, crystalline or amorphous powder. Taste bitter. Almost entirely soluble in 2.5 parts of *water.* Loses acetic acid when exposed to the air. Yields the reactions for morphine described under 'Morphinæ Hydrochloridum,' and the *reactions* characteristic of acetates. 2 grammes form with 5 millilitres of warm *morphinated water* a slightly turbid solution which is rendered clear by the addition of 0.1 millilitre of *acetic acid,* and this solution, when mixed with a slight excess of *solution of ammonia,* yields a white precipitate which, after washing and drying as described under 'Morphinæ Hydrochloridum,' weighs from 1.41 to 1.44 grammes. No appreciable ash." Br.

Uses.—This and the other official salts of morphine are of identical medicinal value. (See *Morphina.*) The solutions for hypodermic use should be freshly prepared, as morphine salts, especially the acetate, are very prone to undergo decomposition, through the growth of a fungus.

Dose, one-twelfth to one-half grain (0.005–0.032 Gm.).

Off. Prep.—Liquor Morphinæ Acetatis, *Br.*

MORPHINÆ HYDROCHLORIDUM.
U. S., Br.

MORPHINE HYDROCHLORIDE Morph. Hydrochl.

"The hydrochloride [$C_{17}H_{19}O_3N.HCl.3H_2O$] of an alkaloid obtained from opium." *U. S.* "Morphine Hydrochloride, $C_{17}H_{19}NO_3,HCl,3H_2O$, is the hydrochloride of an alkaloid, morphine, obtained from opium." *Br.*

Morphinæ Hydrochloras; Morphine Hydrochlorate; Morphine Chloride; Morphiæ Murias; Murias (Hydrochloras) Morphicus; Morphiæ Hydrochloras; Muriate of Morphia; Chlorhydrate de Morphine, *Fr. Cod.;* Morphinum Hydrochloricum, *P. G.*; Morphinhydrochlorid, Salzsaures Morphin, *G.*

A process for this salt is no longer official. The British process (1885) will be found in *U. S. D.*, 17th ed., 882. See also *U. S. D.*, 19th ed., 790.

Description and Physical Properties.—"White, silky, glistening needles or cubical masses, or a white, crystalline powder. It is odorless, and is stable in the air. One Gm. of Morphine Hydrochloride is soluble in 17.5 cc. of water and in 52 cc. of alcohol, at 25° C. One Gm. is soluble in 0.5 cc. of boiling water and in 46 cc. of alcohol at 60° C. It is soluble in glycerin, but insoluble in chloroform and in ether.

"Silver nitrate T.S. added to an aqueous solution of the salt produces a white precipitate, insoluble in nitric acid. Morphine Hydrochloride responds to the tests for identity for morphine under *Morphinæ Sulphas*.

"Morphine Hydrochloride loses not more than 15 per cent. when dried to constant weight at 100° C. (*water*).

"Add 2 cc. of potassium carbonate T.S. to 5 cc. of an aqueous solution of the salt (1 in 30), and gently shake the mixture: a white precipitate is produced, which does not become green on exposure to air, nor color chloroform when shaken with it (*apomorphine*). Morphine Hydrochloride also complies with the tests for purity under *Morphinæ Sulphas*. Preserve in well-closed containers, protected from light." *U. S.*

"Acicular crystals, or a white microcrystalline powder. Taste bitter. Soluble in 25 parts of *water*. 1 drop of *solution of ammonia* added to 5 millilitres of an aqueous solution (1 in 30) produces a white crystalline precipitate easily soluble in *solution of sodium hydroxide*, but soluble with difficulty in excess of *solution of ammonia;* this precipitate yields mere traces to *benzene* (absence of certain other alkaloids). Yields, when moistened with *nitric acid*, an orange-red color; with *T. Sol. of ferric chloride*, a dull greenish-blue. A trace added to 5 millilitres of a very dilute solution of *potassium ferricyanide* to which 1 drop of *T. Sol. of ferric chloride* has been added produces a deep blue color. 0.1 gramme dissolves in 2 millilitres of *sulphuric acid* without coloration, or with the production of not more than a faint pink color; if a portion of this solution is heated on a water-bath for fifteen minutes, cooled, and treated with a few drops of *diluted nitric acid*, a violet coloration, rapidly changing to blood-red, is produced; the addition of *sodium arsenate* to another portion of the original solution produces a bluish-green color. 1 drop of *solution of potassium carbonate* added to 5 millilitres of an aqueous solution (1 in 30) yields a pure white precipitate which does not become colored on exposure to the air, and does not color *chloroform* when shaken with it (distinction from and absence of apomorphine). When 0.5 millilitre of an aqueous solution (1 in 100) is mixed on a white porcelain tile with 0.5 millilitre of *mucilage of starch* in which 0.005 gramme of *iodic acid* has been dissolved, a blue coloration is immediately produced (distinction from morphine esters). Yields the reactions characteristic of chlorides. 2 grammes dissolved in 50 millilitres of warm *morphinated water* give, on the addition of a slight excess of *solution of ammonia*, a white, crystalline precipitate which, when washed with a little cold *morphinated water* and dried, first at 55° to 60° C., and finally for fifteen minutes at 115° C., weighs from 1.50 to 1.52 grammes. Loses about 14 per cent. of its weight when dried at 100° C. No appreciable ash." *Br.*

A saturated solution in boiling water forms a solid crystalline mass on cooling. The solution of morphine hydrochloride, when kept several months, has been known to produce vomiting, through the formation of traces of apomorphine. (*Ph. Centralh.*, 1885, 93.) Potassium hydroxide throws down from its solution a precipitate which is redissolved by an excess of the alkali. The salt is affected by heat, nitric acid, iodic acid, ferric chloride, and chlorine followed by ammonia, in the same manner as morphine. Sugar is said to have been used largely in the adulteration of this salt. It may be detected most readily by the deep red color produced when the adulterated salt is dissolved in strong sulphuric acid. (See *Saccharum*.)

This preparation of morphine is much used in Great Britain, but in this country less than the sulphate. For medicinal properties, see *Morphina*.

Dose, one-twelfth to one-half grain (0.005–0.032 Gm.).

Off. Prep.—Liquor Morphinæ Hydrochloridi, *Br.;* Suppositoria Morphinæ, *Br.;* Tinctura Chloroformi et Morphinæ Composita, *Br.;* Trochiscus Morphinæ, *Br.;* Syrupus Morphinæ et Acaciæ, *N. F.;* Trochiscus Morphinæ et Ipecacuanhæ, *Br.*

MORPHINÆ SULPHAS. U. S.

MORPHINE SULPHATE Morph. Sulph.

"The sulphate [$(C_{17}H_{19}O_3N)_2.H_2SO_4.5H_2O$] of an alkaloid obtained from opium." *U. S.*

Morphiæ Sulphas, *Br.* 1867, *U. S.* 1870; Morphinum Sulphuricum, Sulphas Morphicus; Sulphate of Morphia; Sulfate de Morphine neutre, *Fr. Cod.;* Schwefelsaures Morphium, Morphinsulfat, *G.;* Sulfato morifico, *Sp.*

No process is given in the present U. S. P.; for that of the U. S. P., 1870, see *U. S. Dispensatory*, 19th ed., p. 791. Morphine sulphate is no longer official in the British Pharmacopœia, 1898, the hydrochloride being used in Great Britain, as in Germany, almost exclusively.

Morphine sulphate is prepared from morphine alkaloid, by neutralization with sulphuric acid and careful subsequent concentration of the solution to the crystallizing point. The crystalline masses are then cut into the rectangular blocks so characteristic of this alkaloidal salt. For details of the process as applied on the commercial scale see Calvert (*Pac. Drug.*, June, 1893).

By exposure to a heat of 120° C. it loses 9.66 per cent. of the water, but cannot be deprived of the remainder without decomposition.

The *solution of morphine sulphate* formerly official was made by dissolving 1 grain of morphine sulphate in 1 fluidounce of distilled water, and, although the solution is more stable than that of any other of the morphine salts in common use, it will in time become weakened through the presence of microscopic plants belonging to the Confervoideæ, and hence it is not desirable to keep it on hand.

Description and Physical Properties.—"White, feathery, silky crystals, or cubical masses, or a white, crystalline powder. It is odorless, and is stable in the air. One Gm. of Morphine Sulphate is soluble in 15.5 cc. of water and in 565 cc. of alcohol, at 25° C. One Gm. is soluble in 0.7 cc. of water at 80° C. and in 240 cc. of alcohol at 60° C. It is insoluble in chloroform and in ether.

"Add a few drops of ammonia T.S. to 5 cc. of an aqueous solution of Morphine Sulphate (1 in 30), and gently shake the mixture: a white precipitate is formed, which dissolves upon the subsequent addition of a few cc. of sodium hydroxide T.S. Sulphuric acid containing 0.005 Gm. of selenous acid in each cc. gives with Morphine Sulphate a blue color, changing to green and then to brown. *Codeine* yields a green color changing to blue and afterwards to grass-green. Sulphuric acid containing 0.005 Gm. of molybdic acid in each cc. gives a purple color, changing to blue. Sulphuric acid containing in each cc. one drop of formaldehyde T.S. yields an intensely purple color. With nitric acid Morphine Sulphate produces an orange-red color fading to yellow. The addition of a few drops of freshly prepared ferric chloride T.S. to an aqueous solution of Morphine Sulphate (1 in 100) produces a blue color, which is destroyed by acids, alcohol, or by heating. Add potassium ferricyanide T.S., containing 1 drop of ferric chloride T.S. in each cc. to an aqueous solution of the salt (1 in 100); a deep blue color is produced at once (*difference from codeine*). Barium chloride T.S. produces in an aqueous solution of the salt a white precipitate, insoluble in hydrochloric acid.

"A solution of 0.5 Gm. of the salt in 15 cc. of distilled water requires not more than 0.5 cc. of fiftieth-normal sodium hydroxide for neutralization, using one drop of methyl red T.S. as indicator. Dried to constant weight at 130° C., Morphine Sulphate loses not more than 12 per cent. (*water*). The ash from 0.5 Gm. is negligible. Warm 0.2 Gm. of Morphine Sulphate with 5 cc. of sodium hydroxide T.S.: the odor of ammonia is not noticeable (*ammonium salts*). Add a few drops of ferric chloride T.S. to 5 cc. of an aqueous solution of the salt (1 in 30), previously mixed with 5 cc. of diluted hydrochloric acid: no red color is produced (*meconate*). Dissolve 1 Gm. of Morphine Sulphate in 10 cc. of sodium hydroxide T.S. in a separator, and shake the solution with three successive portions of 15, 10 and 10 cc. of chloroform, passing the chloroform solutions through a small filter previously moistened with chloroform. Shake the combined chloroform solutions with 5 cc. of distilled water, separate the chloroform, and evaporate it carefully to dryness on a water bath. Add to the residue thus obtained 10 cc. of fiftieth-normal sulphuric acid, heat gently until dissolved, cool, add two drops of methyl red T.S., and titrate the excess of acid with fiftieth-normal sodium hydroxide: not less than 7.5 cc. of the latter is required (*foreign alkaloids*).

"Preserve in well-closed containers, protected from light." *U. S.*

In the United States this salt of morphine is used almost to the exclusion of all others. For medicinal properties, see *Morphina.*

Dose, from one-twelfth to one-half grain (0.005–0.032 Gm.).

Off. Prep.—Mistura Chloroformi et Morphinæ Composita, *N. F.;* Syrupus Pini Albæ Compositus cum Morphina, *N. F.*

MORPHINÆ TARTRAS. Br.

MORPHINE TARTRATE

"Morphine Tartrate, $(C_{17}H_{19}NO_3)_2,C_4H_6O_6,3H_2O$, is the tartrate of an alkaloid, morphine, obtained from opium." *Br.*

Morphinum Tartaricum; Tartrate de Morphine, *Fr.;* Morphintartrat, Weinsaures Morphium, *G.*

This salt of morphine was brought into notice by Erskine Stuart (1880), and recommended for hypodermic injection because of its greater solubility in water over the other salts of morphine. (See *Injectio Morphinæ Hypodermica* and *Liquor Morphinæ Tartratis*). It is officially described as "minute acicular crystals, efflorescent at 20° C. Taste bitter. Soluble in 11 parts of *water,* forming a clear solution neutral to litmus. Yields the reactions for morphine described under 'Morphine Hydrochloridum,' and the *reactions* characteristic of tartrates. 2 grammes dissolved in 20 millilitres of warm *morphinated water* give, on the addition of a slight excess of *solution of ammonia,* a precipitate which, after washing and drying as described under 'Morphinæ Hydrochloridum,' weighs from 1.46 to 1.49 grammes. No appreciable ash." *Br.*

A. E. Tanner (*P. J.,* 1903, 134) found morphine tartrate in the English market of low solubility; he investigated the subject and stated that an acid tartrate of morphine was sparingly soluble, that this was found in commerce and that it required 100 parts of cold water for its solution.

Dose, one-twelfth to one-half grain (0.005–0.032 Gm.).

Off. Prep.—Injectio Morphinæ Hypodermica, *Br.;* Liquor Morphinæ Tartratis, *Br.*

MUCILAGO ACACIÆ. U. S., Br.

MUCILAGE OF ACACIA *Mucil. Acac.*
[*Mucilage of Gum Arabic*]

Mucilage of Gum Arabic; Mucilage of Gum Acacia; Mucilage de Gomme, *Fr. Cod.;* Mucilage arabique, *Fr.;* Mucilago Gummi Arabici, *P. G.;* Gummischleim, *G.;* Mucilagine di gomma arabica, *It.;* Mucilago de goma arabica, *Sp.*

"Acacia, in small fragments, 350 Gm.; Sodium Benzoate, 1 Gm.; Distilled Water, a sufficient quantity, to make 1000 cc. Place the acacia in a graduated bottle having a wide mouth and a capacity not exceeding 1000 cc., wash the drug with cold water, allow it to drain, and add enough warm distilled water, in which the sodium benzoate has been dissolved, to make the product measure 1000 cc. After stoppering, lay the bottle on its side, rotating it occasionally, and when the acacia is dissolved, strain the mucilage. Mucilage of Acacia must not be dispensed if it has become sour or mouldy." *U. S.*

"Gum Acacia, 100 *grammes;* Distilled Water, 150 *millilitres.* Rapidly rinse the Gum Acacia with a little *water;* then dissolve it in the Distilled Water in a closed vessel and strain. The Mucilage should be recently prepared. In India and the Eastern Division of the Empire, Mucilage of Indian Gum may be employed in making the official preparations for which Mucilage of Gum Acacia is directed to be used (see 'Gummi Indicum')." *Br.*

This is a very unstable preparation. Numerous suggestions have been made for preserving it. Lime water was employed as a solvent in the U. S. P. VIII, but while the stability of the preparation was improved the incompatibilities of the lime water worked havoc in extemporaneous prescriptions when the physician had forgotten its presence. The only way to have good fresh sweet mucilage of acacia is to make it frequently and use it up rapidly. The addition of sodium benzoate, in the new U. S. formula, while it may serve a useful purpose as a preservative, has objections on the similar ground of incompatibility.

MUCILAGO GUMMI INDICI. Br.

MUCILAGE OF INDIAN GUM

"Indian Gum, 50 *grammes;* Distilled Water, 150 *millilitres.* Rapidly rinse the Indian Gum with a little *water;* then dissolve it in the Distilled Water in a closed vessel and strain. The Mucilage should be recently prepared. In India and the Eastern Divisions of the Empire, Mucilage of Indian Gum may be employed in making the official preparations for which Mucilage of Gum Acacia is directed to be used (see 'Gummi Indicum')." *Br.*

This mucilage was made official in the British Pharmacopœia (1914); it is not as adhesive as the mucilage of acacia.

MUCILAGO TRAGACANTHÆ. U. S., Br.

MUCILAGE OF TRAGACANTH *Mucil. Trag.*

Mucilage de Gomme Adragante, *Fr. Cod.;* Mucilage adragant, *Fr.;* Traganthschleim, *G.;* Mucilagine di gomma adragante, *It.*

"Tragacanth, 6 Gm.; Glycerin, 18 Gm.; Water, a sufficient quantity, to make 100 Gm. Mix the glycerin with 75 cc. of water in a tared vessel, heat the mixture to boiling, remove the heat, add the tragacanth, and macerate during twenty-four hours, stirring occasionally. Then add enough water to make the mixture weigh 100 Gm., stir actively until of uniform consistence, and strain forcibly through muslin." *U. S.*

"Tragacanth, in powder, 1.25 *grammes;* Alcohol (90 per cent.), 2.50 *millilitres;* Distilled Water, sufficient to produce 100.00 *millilitres.* Mix the Tragacanth with the Alcohol; add the Distilled Water as quickly as possible, and shake vigorously." *Br.*

A part only of tragacanth is soluble in water. The remainder swells up and forms a soft tenacious mass, which may be mechanically mixed with water, but does not form a proper solution. Hence trituration is necessary to complete the incorporation of the ingredients. This mucilage is thick and very viscid, but not permanent, as the water separates from the insoluble portion of the tragacanth on standing. It is chiefly used in making pills and troches. The addition of glycerin renders it more serviceable as an excipient. From its great tenacity, it may be advantageously employed for the suspension of heavy insoluble substances, such as the metallic oxides, in water. When kept long, it is apt to undergo decomposition, and to become offensive, but it will keep well if phenol be added. Lyon (*P. J.*, 1901, 600) recommends the use of chloroform water as a preservative in making this mucilage; this is preferred in all cases if the mucilage is not to be used internally. The alcohol in the British process facilitates the quick production of the mucilage, and in addition acts as a preservative.

MYRICA. N. F.

BAYBERRY BARK *Myric.* [*Wax Myrtle Bark*]

"Bayberry Bark is the dried bark of the root of *Myrica cerifera* Linné or *Myrica carolinensis* Miller (Fam. *Myricaceæ*). Bayberry Bark contains not more than 5 per cent. of adhering wood or other foreign organic matter." *N. F.*

Wax Myrtle; Bayberry; Candle Berry; Wax Berry; Candlewood; Candle Tree; Tallow-shrub; Sweet Oak; Tallow Bayberry; Arbre à suif, *Fr.;* Wachsbaum, Wachsgagel, *G.*

Myrica cerifera L. varies from a low, evergreen, diœcious shrub to a tree attaining a height of 12 m. It is found growing in brackish marshes, in sandy soil on the border of brackish ponds and (usually) near the sea, from New Jersey south to Florida, west to Texas and northward to the valley of the Washita River in Arkansas. It possesses crooked branches which form a round-topped head, fragrant, lanceolate-cuneate, coriaceous, evergreen leaves, covered on both surfaces with numerous orange-red and golden-yellow glands, and glandular-dotted catkins of small, apetalous flowers which appear below the leaves on the previous year's wood. The fruits are small, spherical, bluish-white ceriferous nuts, the waxy coating of which has been used along with that from the fruits of the Bayberry (*M. Carolinensis* Mill.) and the hybrids between the Wax Myrtle and Bayberry (*M. Macfarlanei* Youngken) in the production of myrtle wax (see *Vegetable Wax*).

The commercial supplies of the drug come from the states bordering the south Atlantic seaboard. The root bark has been adulterated with the rhizome and aerial stem barks. For distinctions between these three barks see Youngken (*Jour. A. Ph. A.*, 1923, p. 484).

Description and Physical Properties.—"*Unground Bayberry Bark.*—In transversely curved pieces, strips or quills of varying length and breadth and usually 2.5 mm. or less in thickness, rarely up to 5 mm. in thickness (aerial stem bark); outer surface varying from silvery gray to grayish brown or reddish brown, scaly in rhizome and root barks, bearing occasional warts or slight transverse ridges, that of the aerial stem bark exhibiting a number of raised oval lenticels; inner surface reddish brown to brown, finely longitudinally striated, somewhat roughened (rhizome and root barks); fracture short, weak and uneven, the fractured surface reddish brown with short projecting fibers near and along the inner margin of root bark. Odor characteristic; taste astringent, mildly bitter and slightly acrid.

"*Structure.*—Root bark; an outer cork of several layers of suberized cells many of which possess lignified walls, a phellogen, a secondary cortex of cortical parenchyma, some of the cells of which contain tannin, others starch, others rosette crystals or monoclinic prisms of calcium oxalate, while some are more or less filled with a yellowish brown gummy lignin, a broad phlœm separated into a number of phlœm patches by starch-containing medullary-rays which frequently broaden out toward the cortex; phlœm parenchyma with contents similar to those found in the cortical parenchyma; among the cells of both phlœm and cortex numerous fibers and stone cells arranged both singly and in groups, the former often accompanied by crystal fibers containing monoclinic prisms of calcium oxalate. Aerial stem bark similar to the root bark, chiefly distinguished from the latter by possessing a continuous or nearly continuous band of fibers and cells in the pericycle. Rhizome bark differs mainly by the absence of sclerenchyma elements in the cortex, fewer sclerenchyma elements in the phlœm and further by the presence of a discontinuous zone of widely separated islets of narrow, comparatively thin-walled fibers in the pericycle.

"*Powdered Bayberry Bark.*—Reddish brown; numerous simple or 2- to 3- or rarely 4-compound starch grains, the individual grains being spheroidal or plano-convex, often with a central cleft and up to 0.012 mm. in diameter; calcium oxalate crystals chiefly in monoclinic prisms from 0.007 to 0.025 mm. in length, some in the form of rosettes from 0.011 to 0.045 mm. in diameter; numerous strongly lignified fibers with walls up to about 0.038 mm. in thickness; numerous stone cells of varying shape up to 0.125 mm. in length, with thick, lignified, lamellated and porous walls; cork cells polygonal in surface view and frequently with lignified walls; numerous fragments of parenchyma some of the cells rich in starch, others containing gummy lignin which is insoluble in cold or boiling water, cold concentrated sodium hydroxide solution, ammonia, alcohol or xylol but soluble in boiling nitric acid, boiling concentrated sodium hydroxide solution and hot solution of sodium hypochlorite; tracheæ from adhering wood few or absent." *N. F.*

For a detailed study of the *Myricaceæ* of the Eastern United States, see Youngken. (*Contrib. Bot. Lab. U. of Pa.*, 1919, iv, No. 2, p. 339.) *M. Gale* L. (*Sweet Gale, Dutch Myrtle*) has been used as a substitute for hops, and the volatile oil from the green overground portions is known as *Dutch Myrtle Oil.*

The leaves have been used in France as an emmenagogue and abortifacient, and were formerly official in that country under the name of *Herba Myrti Rabantini.* They contain a poisonous volatile oil.

George M. Hambright found in Bayberry bark volatile oil, starch, lignin, gum, albumen, extractive, a red coloring substance, tannic and gallic acids, an acrid resin soluble in alcohol and ether, an astringent resin soluble in alcohol and not in ether, and a peculiar acrid principle having acid properties, *myricinic acid,* which seems to be allied to the saponins. (*A. J. P.*, 1863, 193.)

From the bark of *Myrica Nagi* Thunb., of Japan, the yellow coloring matter of which is known as *myricetin,* A. G. Perkin has separated a glucoside, *myricetrin,* closely resembling *quercitrin.* (See *Proc. Chem. Soc.*, xviii, 11.) For analysis of the rhizome, *Myrica asplenifolia* L., see *A. J. P.*, 1892, 303.

Uses.—Wax Myrtle bark appears to be moderately stimulating and astringent, and in large doses emetic. It has been considerably used by the eclectics in *diarrhea, jaundice, scrofula,* etc. Externally the powdered bark is used as a stimulant to indolent *ulcers,* and the decoction as a gargle and injection in chronic *inflammation of the throat, leucorrhea,* etc.

Dose, of the powder, ten to thirty grains (0.6–2.0 Gm.).

Off. Prep.—Pulvis Myricæ Compositus, *N. F.*

MYRISTICA. U. S., Br.

MYRISTICA Myrist. [Nutmeg]

"Myristica is the dried ripe seed of *Myristica fragrans* Houttuyn (Fam. *Myristicaceæ*), deprived of its seed coat and with or without a thin coating of lime. Myristica yields not less than 25 per cent. of non-volatile, ether-soluble extractive and not more than 0.5 per cent. of acid-insoluble ash." *U. S.* "Nutmeg is the dried kernel of the seed of Myristica fragrans, *Houtt.*" *Br.*

Nux Moschata; Muscade; Noix muscade, *Fr.;* Semen Myristicæ, *P. G.;* Muskatnuss, *G.;* Noce moscata, *It.;* Nuez moscada, *Sp.*

The nutmeg tree is about thirty feet high, with numerous branches, and an aspect somewhat resembling that of the orange tree. The leaves are alternate, petiolate, oblong-oval, pointed, entire, bright green and somewhat glossy on their upper surface, whitish beneath, and of an aromatic taste. The staminate and pistillate flowers are upon different trees. The former are disposed in axillary, peduncled, solitary clusters; the latter are single, solitary, and axillary; both are minute and of a pale yellowish color. The fruit, which appears on the tree mingled with the flowers, is round or oval, of the size of a small peach, smooth, yellow when ripe, and marked with a longitudinal furrow. The external covering, which is at first thick and fleshy and abounds in an austere, astringent juice, afterwards becomes dry and coriaceous, and, separating into two valves from the summit, discloses a scarlet reticulated membrane or arillus, commonly called *mace* (see Part II), closely investing a thin, brown, shining shell, which contains the seed or *nutmeg.*

The tree is produced from the seed. It does not flower until the eighth or ninth year, after which it bears flowers and fruit together, without intermission, and is said to continue bearing for seventy or eighty years. Little trouble is requisite in its cultivation. A branch of the staminate tree is grafted into all the young pistillate plants when about two years old, so as to insure their early fruitfulness. J. H. Hart presented an interesting report (*Bull. Bot. Dept.,* Trinidad, 1907, p. 202) showing that 16-year-old nutmeg trees growing in Trinidad bear both staminate and pistillate flowers. Indeed, he found both kinds of flowers on the same branch of the tree, and he therefore suggests that an attempt should be made to perpetuate this variety by grafting.

The nutmeg tree is a native of the Moluccas and other neighboring islands, and abounds especially in that small cluster distinguished by the name of Banda, whence the chief supplies of nutmegs were long derived. But numerous varieties of the plant are now cultivated in Sumatra, Java, Singapore, Penang, Ceylon, and other parts of the East Indies, and have been introduced into the Isles of France and Bourbon, Cayenne, and several of the West India islands. Various species of the genus *Myristica,* other than the official one, yield commercial seeds or products. The larger part of the nutmegs of commerce is said still to come from the Dutch Banda Islands. The Penang nutmegs are distinguished by not being limed.

In the Moluccas the tree yields three crops annually. The fruit is gathered by hand, and the outside covering rejected. The arillode, constituting the mace of commerce, is then carefully separated, so as to break it as little as possible. It is flattened, dried in the sun, and afterwards sprinkled with salt water, with the view of contributing to its preservation. The nuts are dried in the sun or by ovens, and exposed to smoke until the kernel rattles in the shell. They are then broken open, and the kernels, having been removed and steeped for a short time in a mixture of lime and water, in order to preserve them from the attacks of worms, are next cleaned, and packed in casks or chests for exportation. Lumsdaine has found them to keep better if rubbed over with dry lime than when prepared in the moist way. Tschirch confirms the value of liming as a preservative against the attacks of insects. (*Ph. Rev.,* 1898, 196.) This is, however, not sufficient protection, as the commercial nutmegs are sometimes "wormy." Nutmegs are brought to this country from the British West Indies and either directly from the East Indies or indirectly from England and Holland. About half of the nutmegs entering this country in 1924 came from Grenada in the West Indies, and 40 per cent. was from Java. The other important nutmeg centers are, Sumatra, Banda, Penang, Macassar, Amsterdam, Rotterdam and London. Nutmegs from the East Indies are usually limed while those from the West Indies are not limed.

Shrivelled nutmegs and nutmegs in the shell (whole seeds deprived of arillodes) are imported for distilling purposes.

Description and Physical Properties.—"*Unground Myristica.*—Ovoid or ellipsoidal, from 20 to 30 mm. in length and about 20 mm. in thickness; externally light brown to dark brown; reticulately furrowed, the broad end with a large, circular, upraised scar from which arises a groove extending to a depression at the opposite end; the cut surface having a waxy luster and mottled brown appearance; odor characteristically aromatic, taste pungently aromatic. Perisperm thin, dark brown, penetrating by many wavy branches or folds into the light brown endosperm; embryo small and more or less shrunken, in an irregular cavity near the base.

"*Powdered Myristica.*—Dark reddish-brown; consisting of irregular yellowish-brown and blackish-brown fragments; perisperm with large, circular or elliptical volatile-oil reservoirs, small thin-walled parenchyma cells with brown contents and occasional spiral tracheæ; endosperm with more or less polygonal parenchyma cells containing starch and aleurone grains and occasionally brown pigment; fixed oil globules numerous; starch grains single or compound, the individual grains spherical, plano-convex or polygonal, from 0.003 to 0.020 mm. in diameter, with a distinct, sometimes cleft hilum.

"**Assay.**—Proceed as directed under non-volatile ether-soluble extractive." *U. S.*

"Broadly oval or rounded, rarely more than twenty-five millimetres long; greyish-brown externally, marked with reticulated furrows, and minute black points and lines; internally greyish-red with darker brownish-red veins. Transverse section marbled. Strong aromatic odor; taste aromatic, warm and somewhat bitter." *Br.*

The microscopical structure of nutmeg and mace have been well illustrated by Winton and Moeller in the *"Microscopy of Vegetable Foods."* Spaeth has made an interesting contribution to the pharmacognosy of nutmeg and the detection of the prevalent adulterations in *Ph. Zentralh.*, xlix, p. 627. The quality of present commercial supplies varies considerably. Some shipments arrive which are quite moldy and insect infested. It has been stated that much of the ground nutmeg of commerce has been made from small, stunted and worthless nutmegs, so-called "grinding nutmegs." The powdered drug is sometimes adulterated with corn meal, powdered beans, curcuma and various nut-shells.

Nutmegs have been punctured and boiled in order to extract their essential oil, and the orifice afterwards closed so carefully as not to be discoverable unless by breaking the kernel. The fraud may be detected by their lightness. They are also apt to be injured by worms, which, however, attack preferably the parts least impregnated with the volatile oil. The Dutch were formerly said to heat them in a stove in order to deprive them of the power of germinating and thus prevent the propagation of the tree. The largest nutmegs now command the highest prices. They should be rejected when very light in weight, with a feeble taste and odor, worm eaten, musty, or marked with black veins.

Constituents.—Nutmeg contains from 5 to 15 per cent. of a volatile oil to which it owes its medicinal value (see *Oleum Myristicæ*), from 25 to 40 per cent. of a fixed oil and from 5 to 15 per cent. of an ash; the remainder being starch, fiber, water, etc.

The *concrete* or *expressed oil of nutmeg* (*Oleum Myristicæ Expressum,* Br., 1885, *Oleum Nucistæ,* P. G.), often called *oil of mace,* or *nutmeg butter,* is obtained by bruising nutmegs, exposing them in a bag to steam, and then compressing them strongly between heated plates. A liquid oil flows out, which becomes solid when it cools. This oil may also be obtained by treating nutmeg, thoroughly comminuted, with three times its weight of well-rectified carbon disulphide, agitating the mixture frequently for twenty-four hours, expressing, repeating the process with two parts only of the menstruum, mixing the products of the two macerations, filtering in a covered vessel, and then distilling off the disulphide until the residue is entirely deprived of the solvent. It would seem difficult to prevent the retention of a little of the solvent. The best nutmeg butter is imported from the East Indies in stone jars, or in rectangular blocks 10 inches long by 2½ inches wide, wrapped in palm leaves. It is solid, soft, unctuous to the touch, of a yellowish or orange-yellow color, more or less mottled, with the odor and taste of nutmeg. It is a brownish solid with specific gravity of 0.995 and melting at about 45° C. In 1874 Playfair separated from this a crystallizable fat, *myristin,* which is the glyceride of *myristic acid,* $C_{14}H_{28}O_2$. Power and Salway (*Tr. Chem. Soc.*, 1908, p. 1653) found the expressed oil of nutmeg to contain 73 per cent. of trimyristin, 12.5 per cent. of essential oil, smaller quantities of oleic acid, linoleic acid, resinous material with traces of formic, acetic and cerotic acids, with 8.5 per cent. of unsaponifiable residue. Myristin is also found in spermaceti, in cocoanuts, and in the fixed oil of linseed and poppy oil. It may be obtained directly from nutmeg by exhausting it by means of benzene, filtering the liquid, and allowing it to crystallize by spontaneous evaporation. To purify the product, it may be dissolved in a mixture of two parts of absolute alcohol and three of benzene with the aid of heat, then filtering the liquid while hot, and setting it aside. An inferior kind of the fat is prepared in Holland, and sometimes found in commerce. It is in hard, shining, square cakes, lighter-colored than that from the East Indies, and with less odor and taste. It is supposed to be derived from nutmegs previously deprived of most of their volatile oil by distillation. An artificial preparation is sometimes sold for the genuine oil. It is made by mixing various fatty matters, such as suet, palm oil, spermaceti, wax, etc., adding some coloring substance, and giving flavor to the mixture by the volatile oil.

Allied Products.—Under the names of *long, female,* or *wild nutmeg, Macassar nutmeg, Papua nutmeg, New Guinea nutmeg, horse nutmeg,* certain seeds have long been known in European commerce. These seeds have been variously ascribed to *M. fatua* Houtt. (*M. tomentosa* Thumb., *M. macrophylla* Roxb.), and other species of the genus *Myristica,* but by Bassermann and Warburg have in all their varieties been traced to the *M. argentea* Warburg, of New Guinea, from which country they are often taken to Macassar to finally enter commerce as Macassar nutmegs. (*P. G.*, 1898, 97.) The numerous varieties of these false nutmegs are readily reducible to two, which differ chiefly in size, the larger being commonly known as the Papua nuts, the smaller as the Macassar nuts. They are distinguished from the nutmeg by their greater length, their elliptical shape, their comparatively feeble odor and disagreeable taste, and by the absence of the dark brown veins. (Holmes, *P. J.*, lxxxii, p. 459.) Heckel has described two new so-called wild nutmegs from Madagascar. (*Rep. d. Pharm.*, 1909, p. 49.) Bombay nutmegs from the *M. mala-*

barica Lam. are also long and narrow. They do not possess the characteristic aroma of true nutmegs.

Ucuhula nut is a round or oval seed of *Myristica surinamensis* Roland. It is one-half to two-thirds of an inch in diameter, light brown, but usually covered by a blackish, thin, friable testa. Internally it resembles the nutmeg, but is distinguished by the presence of extraordinarily large and handsome albuminous crystalloids. These seeds are said to contain over 70 per cent. of a solid yellow fat, melting at 36° C. (See *A. J. P.*, 1886; also *A. Pharm.*, July, 1888.) The kernel of the fruit of the Brazilian *Myristica officinalis* Mart. (*M. Bicuhyba* Schott) resembles the nutmeg in form and structure, but is covered with a black shell marked with broad furrows. It contains crystals like those above spoken of, but less splendid and regular, and apt to be in three forms. It yields a fat (*bicuhyba fat,* or *bicuhyba balsam*) very much like that of the ordinary nutmeg, but having a rather sour, sharp taste, melting at 47° C. It contains a peculiar fatty acid, *bicuhybastearic* acid.

The *otoba fat,* sometimes called *american nutmeg butter,* is expressed from the fruit of the *Myristica otoba* H. B. K. which grows in the mountains of Colombia. It is almost colorless and when fresh has a nutmeg-like odor. It consists, according to Baughman and Jamieson (*J. Am. C. S.,* 1921, xliii, p. 199) of more than 50 per cent. of the glyceride of myristic acid with smaller quantities of the glycerides of lauric, oleic and palmitic acids, about 9 per cent. of volatile oil and 9.4 per cent. of an unsaponifiable substance, *otobite.* The latter principle crystallizes in shiny, colorless crystals, melting at 133° C. The fruit of *Virola sebifera* Aubl. (*Myristica sebifera* Sw.) of South America also yields a fatty substance which is known as *ocuba wax,* which is used in the manufacture of candles.

The so-called *California nutmeg* is not a nutmeg at all but the seed of a coniferous tree, *Torreya californica* Torr. It is oblong, with a smooth, thin, brownish testa and exhibits a marbled surface in cross section. Its odor and taste are terebinthinate. Neither are the *Jamaica* or *calabash nutmeg,* from *Monodora Myristica* Dun., the New Holland or *plum nutmeg,* from *Atherosperma moschatum* Labill., and the *clove nutmeg,* from *Ravensara aromatica* J. F. Gmel., true nutmegs.

Uses.—Nutmeg owes its medicinal and toxic properties solely to the volatile oil which it contains. For the consideration of the effects and uses of this, see *Oleum Myristicæ.* Powdered nutmeg is rarely used in medicine alone, although it has been used in *dysentery* (see Leidy, *N. Y. M. R.,* March 1, 1919). It enters into the composition of a number of galenicals. The expressed oil is occasionally used as a gentle external stimulant and was an ingredient in the *Emplastrum Picis* of the 1885 British Pharmacopœia. *Mace* possesses properties essentially the same as those of nutmeg.

Dose, five to twenty grains (0.32–1.3 Gm.).

Off. Prep.—Pulvis Aromaticus, *N. F.;* Tinctura Lavandulæ Composita, *U. S., Br.;* Pulvis Catechu Compositus, *Br.;* Pulvis Cretæ Aromaticus, *N. F., Br.;* Spiritus Armoraciæ Compositus, *Br.*

MYROBALANUM. Br.

MYROBALANS

"Myrobalans are the dried immature fruits of Terminalia Chebula, *Retz.,* usually distinguished in commerce as Chebulic myrobalans." *Br.*

Five varieties of these East India fruits are distinguished by authors. The most important are as follows: (1) *Myrobalani Chebulæ.* This is the only variety which is official. It is produced by the *Terminalia Chebula* Retz. (*Buceras Chebula*). This by some is believed to be identical with the *T. Bellerica* Roxb. noted below. The fruit is roundish or ovate, varying in size from that of a hazel nut to that of a walnut. It consists of an exterior firm fleshy portion and an interior kernel which is light brown, inodorous and with a bitterish, astringent taste.

(2) *Myrobalani Bellericæ.* This is obtained from the *T. Bellerica* Roxb. It closely resembles the previous variety but is of a more grayish-brown color and is sometimes supplied with a short thick foot stalk which is lacking in the official form.

(3) *Myrobalani citrinæ* vel *flava.* These are from a variety of the same tree which affords the chebula myrobalans, from which they differ only in being somewhat smaller, of a light brown or yellowish color, and of a taste rather more bitter. They were formerly sometimes sold in the shops of Philadelphia, under the name of *white galls,* to which, however, they bear no other resemblance than in taste.

(4) *Myrobalani indicæ* vel *nigræ.* These are thought to be the unripe fruit of *T. Buceras* Wright (*Bucida Buceras* L.). They are ovate-oblong, from four to eight lines long and from two to three lines thick, of a blackish color, wrinkled longitudinally, and presenting, when broken, a thick brown mass, without kernel, but with a small cavity in the center. They are sourish and very astringent.

(5) *Myrobalani emblicæ.* This variety is wholly different from the preceding, and derived from a plant having no affinity to the Terminaliæ, of the Fam. *Combretaceæ*—namely, the *Phyllanthus Emblica* L. (Fam. *Euphorbiaceæ*).

Myrobalans are officially described in the Br. Pharm., 1914, as "irregularly ovoid or fusiform, from ten to thirty millimetres or more long and from five to fifteen millimetres wide; strongly shrivelled longitudinally, dark brown or nearly black; in transverse section dark, with a small central cavity; hard. No odor; taste very astringent." *Br.*

When the fruit is entire, it is blackish, spherical depressed, of the size of a cherry, presenting six obtuse ribs with as many deep furrows, and separating into six valves, and has a strongly astringent and acidulous taste. It is often in segments, as found in commerce.

These fruits contain about 30 per cent. of an astringent substance which has been considered to be gallo-tannic acid. According to Freudenberg and Fick (*B. Chem. G.*, 1920, liii, 1728), the astringency is due to a characteristic principle, *chebulinic acid,* which splits up into a crystalline tanning substance, digalloylglucose, and a dibasic acid.

The greenish oleoresin obtained from these fruits is sometimes called *myrobalanin.*

Uses.—Myrobalans were in high repute with the Arabians, and were long employed by European practitioners, as primarily laxative and secondarily astringent, in various complaints, particularly *diarrhea* and *dysentery.* Pierre Apery states that when roasted they are still used in Turkey with excellent results in *intestinal* catarrhs. (*R. T.*, Dec., 1887.) Under the name of *Eutannin* a product asserted by Thoms to be chebulinic acid has been used as an intestinal astringent in dose of from four to ten grains (0.25–0.65 Gm.).

The ointment is used as a local astringent.

The internal *dose* of myrobalans is one-half to one drachm (2.0–3.9 Gm.), given in the form of a powder.

Off. Prep.—Unguentum Myrobalani, *Br.;* Unguentum Myrobalani cum Opio, *Br.*

MYRRHA. U. S., Br.

MYRRH Myrrh. [Gum Myrrh]

"Myrrh is a gum-resin obtained from *Commiphora Myrrha* (Nees) Baillon or from other species of *Commiphora* (Fam. *Burseraceæ*). Myrrh yields not less than 30 per cent. of alcohol-soluble extractive and not more than 4 per cent. of acid-insoluble ash." *U. S.* "Myrrh is an oleo-gum-resin obtained from the stem of Commiphora Myrrha, *Holmes,* and probably other species." *Br.*

Arabian or Somali Myrrh, Herabol Myrrh; Gummi Resina Myrrha; Myrrhe, *Fr. Cod.;* Myrrha, *P. G.;* Myrrhe, *G.;* Mirra, *It., Sp.;* Murr, *Ar.;* Bowl, *Hindost.*

Though *myrrh* has been employed from the earliest times, all the plants yielding it have not been definitely determined. The *Amyris Kataf* of Forskhal, seen by that traveller in Arabia, was supposed by him to be the myrrh tree, but without sufficient proof. Afterwards, in 1820, Ehrenberg discovered myrrh-yielding trees along the eastern shore of the Red Sea in Arabia, at Ghizan and surroundings. From the bark of several of these he collected a gum-resin precisely similar to the myrrh of commerce. From the specimens of the plant taken by Ehrenberg to Germany, Nees von Esenbeck referred it to the genus *Balsamodendron* of Kunth, and named it *Balsamodendron Myrrha.* This has since proven to be the *Commiphora Myrrha* (Nees) Engler or one of the true Myrrh trees. It was not thought by De Candolle sufficiently distinct, but is now generally recognized under the name of *Commiphora,* first given it by Jacquin in 1797, and therefore preceding the name of Kunth by some 27 years. Berg found another species in Ehrenberg's collection, to which was attached a label by the discoverer, stating that he had collected myrrh from it, and proposed to call it *Balsamodendron ehrenbergianum.* (*A. J. P.*, 1873, 314.) Both Oliver and Trimen agree that this plant is not specifically distinct from *B. Opobalsamum.* Gum resins from several species of *Commiphora* furnish commercial myrrh. Hildebrand (*P. J.*, 1878, ix, p. 893) collected the *C. Myrrha* on the north Somali coast in 1873, and presents evidence to show that it yields myrrh. Although this view has been disputed, E. M. Holmes (*Y. P. B.*, 1913, p. 453) supports it and this species is recognized by the British Pharmacopœia. Deflers and Schweinfurth (*B. P. G.*, 1893), however, believe that genuine myrrh is yielded by *Commiphora abyssinica* (Berg.) Engl., which is found in Southern Arabia, Erithrea, and Northern Abyssinia. *C. Schimperi* (Berg.) Engl., occurring in the Yemen, Abyssinia, and from Kern to Tigré, is likely also to yield some of the commercial Arabian myrrh. It appears to be established that *C. Myrrha* produces myrrh, but it is probable that it is also yielded by other trees belonging to the genus *Commiphora,* which genus includes more than 60 species, natives of Arabia and Africa.

Commiphora Myrrha (Nees) Engler (Syn. *C. Myrrha* Holmes) is a small tree, with a stunted trunk, covered with a whitish-gray bark, and furnished with rough abortive branches terminating in spines. The leaves are ternate, consisting of obovate, blunt, smooth, obtusely denticulate leaflets, of which the two latter are much smaller than the one at the end. The fruit is oval-lanceolate, pointed, longitudinally furrowed, of a brown color, and surrounded at its base by the persistent calyx. The tree grows along the Red Sea in Arabia in the neighborhood of Gison, in dwarfish thickets, interspersed among the *Acaciæ* and *Euphorbiæ.* It also thrives in Somaliland. The juice concretes spontaneously upon the bark.

Myrrh is now collected in Somaliland and Arabia by making incisions into the bark of the trees, when a yellowish oleoresin exudes. Upon hardening this exudate becomes reddish-brown and is gathered. Some of the oleoresin which collects within the secretion reservoirs of the bark exudes spontaneously. This represents but a small proportion of the drug collected. Other gums and resins as well as considerable bark is found in the crude article which is more or less removed before it is sent into commerce. The greater bulk of the drug comes from Somaliland (Northeast Africa). This is sent to Aden whence it is shipped to Europe and America either direct or through Bombay. It is usually imported in chests containing between one and two hundred-weight. Sometimes the different qualities are brought separate, but oftener more or less mingled. Only the best kind should be selected for medicinal use.

There are several varieties of myrrh recognized in commerce. The official description corresponds to that of that known as the Arabian myrrh or Somaliland myrrh.

Another variety of myrrh coming from Arabia known as the *Fadhli* (*Fahdi*) *myrrh* is described in the *Pharmacographia* as "occurring in irregular masses, seldom exceeding 1½ inches long, and having a somewhat gummy-looking exterior. The larger lumps seem formed by the cohesion of small, rounded, translucent, externally shining drops or tears. The fracture is like that of common myrrh, but less unctuous, and has not the whitish markings. The odor and taste are those of the ordinary drug." This myrrh is said to be collected on the hills about Shugraeea and Sureeae, east of Aden. "*Meetiyu*," or *Arabian Myrrh of Dymock*, is said to be sold in India as true myrrh. It has a dull surface, a dark reddish-brown color, a more unctuous and waxy fracture, and has white marks like Somali myrrh, which it resembles in taste, but its odor is rather less fragrant. *Yemen Myrrh*, which is said by Hanbury to contain a resin, which differs from that of Somali myrrh and the Arabian myrrh, or Fahdi, in that its solution in petroleum spirit does not give a violet color on the addition of bromine. This myrrh is said to enter commerce chiefly from Makulla via Aden and Bombay. It occurs in large pieces 1 to 3 inches long, irregularly rounded and characterized by a dark reddish-brown color with a similarly colored fracture free from white streaks. Odor and taste similar to Somali myrrh, but stronger and more rank. *Heerabol* (or *Herabol*) myrrh is a variety obtained from a tree known locally as *Didthin*, which is probably the *C. Playfairii* (Hook. f.) Engl. *Bissabol*, or *East Indian Myrrh* seems to be the perfumed bdellium (see *Bdellium*, Part II).

Mecca balsam, according to G. Schweinfurth, is yielded by *Commiphora Opobalsamum*, from which it is collected in the valleys near Mecca. It is said to be the myrrh of the Bible, the error of translation having been made on account of the similarity of the old Hebrew word "mar" with the modern Arabic word "morr," the name of the true myrrh.

Description and Physical Properties.—"*Unground Myrrh.*—Rounded or irregular tears or masses of agglutinated tears, brownish-yellow or reddish-brown and more or less covered with a grayish or yellowish dust; fracture waxy, granular, conchoidal, internally deep yellowish or reddish-brown, sometimes marked with nearly white spots or lines, oily, translucent at the edges; odor balsamic, aromatic; taste aromatic, bitter and acrid.

"*Powdered Myrrh.*—Yellowish-brown; consisting of numerous angular fragments of resin and gum, a few fragments of lignified tissue and a very few starch grains.

"**Assay.**—Proceed as directed under alcohol-soluble extractive." *U. S.*

"In rounded or irregular tears, or masses of agglutinated tears, varying much in size; reddish-brown or reddish-yellow externally, dry, and more or less covered by a fine powder; brittle, the fractured surface irregular, somewhat translucent, of a rich brown color, oily, and frequently exhibiting whitish marks. Aromatic odor; taste aromatic, bitter and acrid. Not more than 70 per cent. insoluble in *alcohol* (90 per cent.). The solution obtained by boiling 0.1 gramme of coarsely powdered Myrrh with 2 millilitres of *alcohol* (90 per cent.), evaporated in a porcelain dish so as to leave a thin film, yields a residue which assumes a violet color in contact with *nitric acid* diluted with an equal volume of *water*. Ash not more than 5 per cent." *Br.*

Under the teeth it is at first friable, but soon softens and becomes adhesive. It is inflammable, but does not burn vigorously, and is not fusible by heat. Its sp. gr. is stated as 1.36. The inferior kind is in pieces much darker, more opaque, less odorous, and often abounding with impurities. We have seen pieces of India myrrh enclosing large crystals of sodium chloride, as if the juice had fallen from the tree and concreted upon the ground where this mineral abounds. Pieces of *bdellium*, and other gummy or resinous substances of unknown origin, are often mixed with it. Among these is a product which may be called *false myrrh*. It is in irregular pieces, of a dirty reddish-brown color, a vitreous brownish-yellow fracture, semi-transparent, of a faint odor of myrrh, and a bitter balsamic taste. Myrrh is best purchased in mass, as in powder it is liable to adulterations not easily detected. It is sometimes admixed with small stones which are added when the myrrh is in a moist state. It has been adulterated with senegal gum and chestnuts.

George F. Merson (*P. J.*, Jan., 1900, 42) proposes as a test of the quality of myrrh that it should yield not more than 5 per cent. of ash, which should be almost entirely soluble in diluted hydrochloric acid, and that when exhausted with 90 per cent. alcohol and dried at 100° C. one gramme should not afford more than 0.6 Gm. of residue.

Myrrh is partially soluble in water, alcohol, and ether. Triturated with water it forms an opaque yellowish or whitish emulsion, which deposits the larger portion upon standing. Its alcoholic tincture is rendered opaque by the addition of water, but throws down no precipitate. According to Neumann, alcohol and water severally extract the whole of its odor and taste. By distillation a volatile oil arises, having the peculiar flavor of myrrh, and leaving the residue in the retort simply bitter. The gum-resin is soluble in solutions of the alkalies, and, when triturated with them in a crystalline state, forms a tenacious liquid. Hence potassium carbonate may be used to facilitate its suspension in water. Hirschsohn recommends as a reagent for myrrh, trichlor-acetal-chloroform, which is obtained by conducting chlorine into seventy-five per cent. alcohol until turbidity ensues and two layers are formed; the lower of these is shaken with an equal volume of water and then with calcined magnesia and filtered. In one part by weight of the trichloracetal thus obtained, four parts by weight of hydrated chloral are dissolved by heating. The syrupy reagent thus made, which fumes slightly in the air, gives a violet color with the smallest quantity of pure Herabol myrrh. Hirschsohn failed to get a similar reaction with any other resin, not even with Bisabol myrrh. (*Ph. Centralh.*, 1903, 809.)

According to Bley and Diesel myrrh containing a little volatile oil always has an acid reaction, which they ascribe to the oxidation of the oil. They propose as a test of myrrh the production of a transparent dirty-yellow liquid with nitric acid, while false myrrh affords a bright-yellow solution in the same fluid, and bdellium is not dissolved, but becomes whitish and opaque. (*A. J. P.*, xviii, 228.) According to Righini, if powdered myrrh, rubbed for fifteen minutes with an equal weight of ammonium chloride, and fifteen times its weight of water gradually added dissolves quickly and entirely, it may be considered pure.

Constituents.—The chemistry of myrrh is in a very unsatisfactory state; the various constituents reported as present must be looked on as questionable and the formulas assigned to them as purely empirical. In a general way myrrh consists of about 25 to 45 per cent. of resin, 30 to 40 per cent. of gum, 3 to 8 per cent. of volatile oil, with traces of free acetic, formic and *myrrholic* acids and small amounts of water and inorganic salts.

The volatile oil has been called *myrrhol* or *myrrhenol*, and, according to Ruickoldt, has the formula $C_{10}H_{14}O$. Koehler (*A. J. P.*, 1890, p. 346) confirms this formula, and states that this body, while isomeric with thymol and carvol, is distinct from them. He found 7 or 8 per cent. of essential oil. Gladstone (*J. Chem. S.*, [2], 2, 1) found that the oil had a sp. gr. of 1.0189 at 7.5° C., a boiling point of 266° C., and was lævorotatory. Friedrichs (*A. Pharm.*, 1907, ccxlv, 427) found 8.8 per cent. of essential oil having a sp. gr. 1.011 and an optical rotation 73.86°. He also reported a new tricyclic sesquiterpene, *heerabolene*, $C_{15}H_{24}$.

The resin Gladstone suggested to call *myrrhin.* He gave the formula $C_{48}H_{32}O_{10}$; it is neutral, but becomes acid when kept for a short time in fusion. In the latter state Ruickoldt proposes to call it *myrrhic acid.* (*A. Pharm.*, lxi, 1.) Koehler has found in the portion soluble in alcohol an indifferent soft resin, to which he gave the formula $C_{26}H_{34}O_5$, containing three replaceable OH groups, and two dibasic resin acids, of the formulas $C_{26}H_{32}O_{16}$ and $C_{26}H_{32}O_9$. Friedrichs gives the following constituents: *Commiphorinic acid,* $C_{28}H_{36}O_8$; *alpha-heerabomyrrhol,* $C_{18}H_{26}O_5$; *beta-heerabomyrrhol,* $C_{20}H_{26}O_6$; *heeraboresene,* $C_{42}H_{56}O_8$; *alpha-myrrholdic acid,* $C_{15}H_{22}O_7$; *beta-myrrholdic acid,* $C_{25}H_{32}O_6$; an unidentified monatomic alcohol, $C_{14}H_{22}O_2$.

An investigation of the essential oil of Bissabol myrrh from the interior of the Somali country was made by W. Tucholka. (*Schim. Rep.*, Oct., 1897, 36.) He obtained by distillation 7.8 per cent. of an oil of 0.8836 sp. gr., boiling at from 220° to 270° C. From this was separated, by means of the crystalline hydrochloride, a terpene boiling at from 259° to 260.2° C., which the author calls *bissabolene,* and an oxygenated portion to which he gives the rather strange formula $C_{56}H_{96}O$.

The gum appears to consist largely of arabin and yields a good mucilage; when making tincture of myrrh, the residue insoluble in the alcoholic menstruum should be saved for that purpose.

Uses.—Although myrrh has been an important article of commerce from times of the greatest antiquity, it was cherished chiefly as a constituent of incense and perfumes, rather than for medicinal properties. By the ancient Greek physicians it was used as a local remedy and apparently, to some extent, also internally. It probably, however, does not possess any important therapeutic virtues which are not found in many other resinous substances. Like so many of the resins it is locally stimulating and may, perhaps, for this reason excite peristalsis in the alimentary tract; it is therefore used as an ingredient of certain cathartic pills and occasionally in atonic *dyspepsia.* The older writers believed that it was capable of absorption and useful in chronic *bronchitis* and certain types of *amenorrhea.* Its most important use today is as an aromatic stimulant mouth wash.

Myrrh may be given in the form of powder or pill, or suspended in water, as in the famous antihectic mixture of Griffith. (*Mistura Ferri Composita.*) The infusion is also sometimes given, and an aqueous extract has been recommended as milder than myrrh in substance. The tincture is used chiefly as a local application.

Dose, five to twenty grains (0.3–1.2 Gm.).

F.;* Tinctura Capsici et Myrrhæ, *N. F.*

NEOARSPHENAMINA. U. S.

NEOARSPHENAMINE Neoarsphen.

"Neoarsphenamine is a product obtained by the action of sodium methanol sulphoxylate on arsphenamine, and consists partially of sodium

3-diamino 4-dihydroxyarsenobenzene methanol sulphoxylate [$NH_2.OH.C_6H_3As:AsC_6H_3.OH.NH(CH_2O)OSNa$]. It contains not less than 19 per cent. of As, and complies with the requirements of the United States Public Health Service. Neoarsphenamine is distributed in sealed containers of colorless glass, from which the air has been excluded either by the production of a vacuum or by displacement with a nonoxidizing gas." *U. S.*

Neosalvarsan; Novarsenobenzol; Neokharsivan.

The difficulties and inconvenience involved in preparing arsphenamine for injection directed research toward the discovery of a soluble derivative which would be neutral and still retain its effectiveness. The most satisfactory derivative tried was the methylene sulphinate which was prepared by acting upon a compound of arsphenamine with sodium formaldehyde sulphoxylate.

It is prepared as follows: Arsphenamine dihydrochloride is dissolved in ten times its weight of water and is treated with an equal volume of a ten per cent. solution of sodium formaldehyde sulphoxylate. After allowing the mixture to stand for an hour a 10 per cent. solution of sodium carbonate is added to make a clear solution. The subsequent addition of a 12 per cent. hydrochloric acid solution precipitates a methylene sulphinic acid derivative of arsphenamine, containing one CH_2SO_2H group. This derivative is converted into the normal sodium salt by the careful addition of solution of sodium hydroxide and the resulting neoarsphenamine is precipitated by the addition of a large volume of strong alcohol or of acetone and is then washed and dried under reduced pressure.

In another method the reaction between arsphenamine base and sodium formaldehyde sulphoxylate is carried out in ethylene glycol as a solvent.

Neoarsphenamine may also be prepared directly from 3-nitro-4-hydroxyphenyl-arsenic acid.

According to Roth (*U. S. Pub. Health Rep.*, 1921, xxxvi, 2523), it is not a definite chemical compound.

Description and Physical Properties.—" A yellow powder. It is odorless or has a slight odor. In the dry state or in solution it is readily oxidized by exposure to the air, becoming darker and more toxic. Higher temperatures accelerate the oxidation. It is very soluble in water, soluble in glycerin, slightly soluble in alcohol and almost insoluble in acetone, chloroform, and in ether.

" An aqueous solution of Neoarsphenamine (1 in 100) is neutral or slightly alkaline to litmus paper (*difference from arsphenamine*). An aqueous solution of Neoarsphenamine (1 in 100) is precipitated by diluted mineral acids (*difference from arsphenamine*), but yields no precipitate with solutions of alkali hydroxides or carbonates, and is not precipitated by mercuric potassium iodide T.S. (*difference from arsphenamine*). The addition of 2 drops of freshly prepared ferric chloride T.S. to 5 cc. of an aqueous solution of Neoarsphenamine (1 in 1000) produces a purple or purplish-red color, changing to dark red. Add 3 cc. of silver nitrate T.S. to 5 cc. of an aqueous solution of neoarsphenamine (1 in 100): a brown precipitate is immediately formed, rapidly becoming black (*difference from arsphenamine*). To 10 cc. of an aqueous solution of Neoarsphenamine (1 in 100) add 10 cc. of diluted hydrochloric acid, and heat: the odor of sulphur dioxide is perceptible. The solution resulting from the assay for arsphenamine directed below yields with hydrogen sulphide a yellow precipitate soluble in ammonium carbonate T.S. Add 5 cc. of distilled water to 0.5 Gm. of Neoarsphenamine in a test tube, and gently agitate the mixture: a complete solution results in five minutes.

" **Assay.**—Proceed as directed under *Arsphenamine.*

" Preserve in the original sealed tubes in a cool place, preferably not above 10° C.

" *Caution—Solutions of Neoarsphenamine must be freshly prepared when required for use.*" *U. S.*

Roth (*J. A. M. A.*, 1922, lxxxviii, 1191) has found that even in sealed ampules neoarsphenamine undergoes chemical changes, some samples showing obvious deterioration in a few weeks. These changes—which may be manifested by such obvious alterations as lower solubility or difference in color—take place much more rapidly at warmth; he advises, therefore, that the drug be kept under the same storage conditions as biological products. The U. S. recommends that it be stored at a temperature of 10° C.

Uses.—Neoarsphenamine is employed in medicine for the same purposes as arsphenamine (*q. v.*). The question of the relative therapeutic efficiency of the two compounds can not as yet be positively answered. Although it contains two-thirds as much arsenic as arsphenamine according to Schamberg (*J. A. M. A.*, 1919, lxxiii, 1883) it requires about twice the dose to exercise the same degree of spirocheticide action. The comparative value of the two drugs depends, however, not merely on their activity but also on their relative toxicity. This latter point is very difficult to accurately determine; Shamberg, Kolmer and Raiziss (*A. J. M. S.*, 1920, clx, 188) find that for rats neoarsphenamine is less than half as poisonous when injected intravenously, but almost equally toxic when given subcutaneously.

It is administered by the same methods and with the same precautions as arsphenamine.

Dose, from eleven to fourteen grains (0.6–0.9 Gm.).

NITROGENII MONOXIDUM. U. S.

NITROGEN MONOXIDE Nitrogen. Monox.
[Nitrous Oxide]

"Nitrogen Monoxide gas [N_2O]." *U. S.*

Laughing gas; Oxyde nitreux, Potoxide d'Azote, *Fr.;* Stickstoffoxydul, Lachgas, *G.*

This gas was originally discovered by Priestley in 1776, but first brought into general notice in 1800 by Humphry Davy, who discovered and made known the remarkable exhilarating properties which earned for it the name of laughing gas.

Preparation.—In its preparation, pure fused ammonium nitrate is submitted to a heat sufficient to decompose it, not exceeding 204.4° C., and the resulting gas collected and purified. When ammonium nitrate is heated to the point of decomposition, it is wholly resolved into aqueous vapor and nitrogen monoxide, according to the reaction:

$$NH_4.NO_3 = 2H_2O + N_2O$$

It is necessary not to let the heat employed in the process be too high, as otherwise, besides nitrous oxide, there will come over portions of nitric oxide, uncombined ammonia, even nitric acid. At times nitrogen gas is also found in the nitrogen monoxide, probably resulting from a trace of nitrite present or some reducing action upon the nitrate in the moment of its decomposition. When the monoxide is liquefied under pressure this free nitrogen remains as unliquefied gas.

Properties.—Nitrogen monoxide gas is colorless, inodorous, slightly sweetish to the taste, and of the sp. gr. 1.527 compared with air. Cold water will absorb about three-fourths of its bulk of the gas, and, under pressure, much more, and, thus impregnated, has a slight, not unpleasant odor, and a sweetish taste. By the joint influence of cold and pressure the gas may be condensed into a colorless, very mobile liquid. Liquid nitrogen monoxide has a sp. gr. of 0.9367 and a boiling point (at atmospheric pressure) of –89.8° C. Inflammable bodies will generally burn with increased vigor in nitrous oxide gas, but it is entirely incapable of giving oxygen to the blood.

Description and Physical Properties.—"A colorless gas, having a slight characteristic odor and a somewhat sweet taste. It supports the combustion of many substances. For convenience in handling and use, Nitrogen Monoxide is compressed in metallic cylinders.

"It is quite soluble in water at low temperatures; 1 volume of water dissolves about 1.3 volumes of nitrous oxide at 25° C.

"Pass 2000 cc. of the gas, measured under normal atmospheric pressure at about 25° C., through 100 cc. of barium hydroxide T.S. at a rate not exceeding 4000 cc. per hour: the turbidity produced, if any, is not greater than that produced by 1 cc. of a solution prepared by dissolving 0.2 Gm. of sodium bicarbonate in 100 cc. of freshly boiled distilled water (*carbon dioxide*). Pass 2000 cc. of Nitrogen Monoxide, under the conditions described above through a mixture of 100 cc. of distilled water and 1 cc. of silver nitrate T.S.: no opalescence is produced (*halogens*). Pass 2000 cc. of Nitrogen Monoxide through 100 cc. of distilled water, colored with 5 drops of litmus T.S., under the conditions described above: the color of the liquid is not changed (*acids or alkalies*). Pass 2000 cc. of Nitrogen Monoxide through a solution of 0.2 cc. of tenth-normal potassium permanganate in 100 cc. of distilled water: the color of the liquid is not changed (*reducing substances*)." *U. S.*

Uses.—Although Sir Humphrey Davy as far back as 1800 suggested the use of nitrous oxide for the production of anesthesia, the first practical employment of it was in 1844 by Horace Wells, of Connecticut. Nitrous oxide is remarkable among anesthetics in being almost physiologically inert, save in its effect on the cerebrum. While as it is ordinarily administered there are marked alterations in the circulation owing to partial asphyxia, by carefully combining pure oxygen with the gas it is possible to induce with nitrous oxide a state of complete anesthesia without any considerable change in either the rapidity of the pulse, the blood pressure, or the respiration. It differs also from the liquid anesthetics in that it is not depressant to the spinal cord. For operations of short duration, such as extraction of teeth, opening of abscesses, and the like, it should always be the anesthetic of preference, if available. The mortality in this group of operations is almost nil; it has been estimated variously as from one death in a hundred thousand to one in a million. The two great drawbacks to its more frequent employment are its cumbersomeness of transportation and the shortness of the narcosis. By administering it in conjunction with pure oxygen the inhalation may be continued for long periods of time, so that it can be employed in major operations. There is, however, great difference of opinion as to the advisability of its use for this purpose; Crile (*J. A. M. A.*, 1910, liv), who has had a large experience with it, believes that with a skilful anesthetist it is safer than ether, but that in the hands of the inexperienced is more dangerous.

NUX VOMICA. U. S., Br.

NUX VOMICA Nux Vom. [Strychni semen, P. I.]

"Nux Vomica is the dried ripe seed of *Strychnos Nux-vomica* Linné (Fam. *Loganiaceæ*). Nux Vomica yields not less than 2.5 per cent. of the alkaloids of Nux Vomica." *U. S.* "Nux Vomica consists of the dried ripe seeds of Strychnos Nux-vomica, *Linn.*" *Br.*

Semen Nucis Vomicæ; Poison Nut, Quaker Buttons, Dog Buttons; Noix vomique, *Fr. Cod.;* Semen Strychni,, *P. G.;* Krähenaugen, Brechnuss, *G.;* Noce vomica, *It.;* Nuez vomica, *Sp.*

Strychnos Nux-vomica is a tree of a moderate size, with numerous strong branches, covered with a smooth, dark gray bark. The young branches are long, flexuous, smooth, and dark green, with opposite, ovate, petiolate, entire, smooth, and shining leaves. The flowers are small, white, funnel-shaped and in terminal corymbs. The fruit is a round berry, about as large as an orange, with a smooth, yellow or orange-colored, hard, fragile rind, and many seeds in a juicy pulp. It has frequently been asserted that the pulp is innocuous, but Flückiger and Hanbury, and also Dunstan and Short (*P. J.*, 3d series, xv, 1) have demonstrated that it contains strychnine. Dunstan and Short have also proved that of the commercial varieties of nux vomica, Bombay seed stands first in percentage of contained strychnine, then Cochin, and lastly Madras. (*P. J.*, 1883, xiv, 1053.)

The tree is a native of India, growing in Bengal, Malabar, on the Coromandel Coast, in Ceylon, in many islands of the Indian Archipelago, in Cochin China, and in Northern Australia. The fruits are collected when fully mature and the seeds removed from the pulp by washing, or the pulp may be rotted off the seeds. They are then dried in the sun on mats, graded and marketed. Most of the world's supply comes from India, two-thirds of the available supply being furnished by the Madras Presidency. The chief importers are the United States and Great Britain. The drug is largely shipped to the United States in small sacks from Madras, Cochin, Cocanada, Calcutta and Bombay, some coming indirectly through London.

The wood and root are very bitter, and were employed in the East Indies for the cure of intermittents. The *radices colubrinæ* and *lignum colubrinum* of the older writers, long known in Europe as narcotic poisons, have been ascribed to this species of *Strychnos*, under the impression that they were identical with *Strychnos colubrina*, to which Linnæus refers them. They were ascertained by Pelletier and Caventou's researches to contain a large quantity of strychnine. The bark has been mistaken for cusparia, and hence is sometimes referred to as *false angustura*. Gehe & Co. (*Handelsbericht*, 1914, p. 119) state that a new variety of nux vomica, the origin of which is unknown, is being exported from Burma. The seeds are externally light gray, internally yellow and are devoid of strychnine. For a description of commercial varieties of nux vomica seeds, see a paper by Youngken and Slotter in *A. J. P.*, 1920, p. 538.

Description and Physical Properties.—" *Unground Nux Vomica.*—Seed orbicular, nearly flat, occasionally somewhat bent, from 10 to 30 mm. in diameter, and from 4 to 5 mm. in thickness; externally grayish or greenish-gray, covered with appressed hairs, giving it a silky luster; hilum indicated by a circular scar at the center of one of the flattened sides, and connected with the micropyle by a ridge; very hard when dry; internally showing a thin and hairy seed-coat and a large grayish-white endosperm at one end of which is embedded a small embryo with two broadly ovate, 5- to 7-nerved cotyledons; inodorous; taste intensely and persistently bitter.

" *Powdered Nux Vomica.*—Light gray; consisting chiefly of thick-walled endosperm cells containing globules of a fixed oil and a few small aleurone grains; and fragments of strongly lignified, non-glandular hairs, the walls of the latter possessing large, circular, or long, slit-like pores. In the tissues of the adhering pulp occur a few small, nearly spherical starch grains." *U. S.*

" Seeds disc-shaped, nearly flat, but sometimes irregularly bent; rounded or somewhat acute at the margin, from a small prominence on which a raised line passes to the central hilum. Ash-grey or greenish-grey. From two to two and a half centimetres in diameter, and about six millimetres thick. Surface densely covered with short, satiny, radiately arranged and closely appressed hairs. Endosperm large and horny; cotyledons small and leafy. Powdered Nux Vomica exhibits fragments of the endosperm, the cell-walls of which are very thick but not lignified, also slender rod-like fragments of the hairs and their thickened, pitted, lignified basal portions. No odor; taste extremely bitter. Yields not less than 1.25 per cent. of strychnine when tested by the following process." *Br.*

The seeds are destitute of odor, but have an acrid, very bitter taste, which is much stronger in the kernel than in the investing membrane. They impart their virtues to water, but more readily to diluted alcohol. For a method of distinguishing powdered nux vomica from powdered ignatia and other powders, see *Proc. A. Ph. A.*, 1897, 503.

Herder has proposed a detection of the alkaloids in nux vomica by various microchemical means and shows how they may be localized in the seeds and growing plants. (*A. Pharm.*, 1906, p. 129.) Tunmann (*A. Pharm.*, 1910, 644) has studied the distribution of the alkaloids in the germinating seeds of *Strychnos Nux-vomica*, and concludes that the embryo of the seed contained only brucine and that strychnine, which was contained in the endosperm only in the cell plasma of the cell content, appears to act as a protection for the growing plant. Grutterink has also published an illustrated article on the microchemical examination of the several alkaloids of nux vomica. (*Zeit. An. Chem.*, li, p. 187.) Rusby has reported the shipment of nux vomica which consisted of small inferior seeds which had been rolled in some mixture of clay. (*Proc. A. Ph. A.*, 1908, lvi, p. 794.) Powdered nux vomica has been adulterated with ground olive stones and the raspings of vegetable ivory. (See *Rep. d. Pharm.*, 1909, p. 241; *Ann. d. chim. Analyt.*, 1909, p. 261.)

Assay.—" Place 10 Gm. of Nux Vomica, in fine powder, in a 250 cc. flask, add 100 cc. of ether-chloroform mixture, and proceed by Type Process A. Decant 50 cc. of the ethereal solution to complete the assay, using chloroform as the immiscible solvent in shaking out the alkaline liquid, and determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.0364 Gm. of the total alkaloids of Nux Vomica (Proximate Assays)." *U. S.*

"Shake 7.5 grammes of Nux Vomica in No. 60 powder frequently during half an hour with a mixture of 25 millilitres of *chloroform,* 50 millilitres of *ether,* and 5 millilitres of *solution of ammonia.* Transfer 50 millilitres of the clear ethereal liquid to a separator, and extract the alkaloids, by shaking with three successive portions, each of 10 millilitres, of *N/1 solution of sulphuric acid,* transferring the acid solutions to a second separator. Make the acid solutions alkaline with *solution of ammonia,* and again extract the alkaloids by shaking successively with 10, 5, and 5 millilitres of *chloroform,* drawing off the chloroformic solutions into a small flask. Recover the chloroform by distillation, dissolve the residue in a mixture of 5 millilitres of *diluted sulphuric acid* and 10 millilitres of water, heat the solution to 50° C., add 3 millilitres of a mixture of equal volumes of *nitric acid* and *water,* and set aside for ten minutes. Transfer the solution to a separator, rinsing the flask with a little *water,* make alkaline with *solution of sodium hydroxide,* and extract the alkaloid by shaking successively with 10, 5, and 5 millilitres of *chloroform.* Wash the mixed chloroformic solutions in a separator with 5 millilitres of *water,* transfer to a tared dish and allow the chloroform to evaporate, adding towards the end 5 millilitres of *alcohol* (90 per cent.). Evaporate to dryness, dry the residue at 100° C., and weigh. This weight, multiplied by 20, is the weight of strychnine in 100 grammes of the powdered Nux Vomica. Powdered Nux Vomica, when used for official purposes other than the production of standardised preparations, must be adjusted, if necessary, by the addition of powdered Milk Sugar to contain in 100 grammes 1.25 grammes of strychnine when tested by the foregoing process. *Limit of error* 0.05 gramme in excess or defect." *Br.*

The U. S. assay determines the total amount of alkaloid but in the Br. method the brucine is destroyed by the treatment with nitric acid and the final result represents the proportion of strychnine. Schweissinger recommended the direct determination of the alkaloids in nux vomica by titration with hydrochloric acid as the best way of ascertaining the strength of pharmaceutical preparations. (*A. Pharm.,* 1885, 579.) Keller's method of estimating the alkaloids in nux vomica (see *Proc. A. Ph. A.,* 1895, 1024) is commended by Sander. (*A. Pharm.,* 1897, 133; see also *A. J. P.,* 1896, 189.) A method of assay for nux vomica and its preparations has been proposed by M. Azadain (*P. J.,* xciii, 371) which involves the precipitation of the alkaloids by silico-tungstic acid.

Constituents.—Pelletier and Caventou discovered in nux vomica two alkaline principles, *strychnine* and *brucine,* united with a peculiar acid which they named *igasuric.* Shenstone (*J. Chem. S.,* 1881, xxxix, 453) has shown that the *igasurine* of Desnoix is a mixture of strychnine and brucine. Boorsma discovered a new alkaloid in the leaves of *S. Nux-vomica* (*Bull. de l'Inst. Bot. de Buitenzorg,* 1902) and he named it *strychnicine;* it is only slightly poisonous. (See also *P. J.,* 1902, 65.)

Hugo H. Schafer (*J. A. P. A.,* 1914, p. 1077) announced a new alkaloid in nux vomica which he has named *struxine,* $C_{21}H_{30}O_4N_2$. It is present only in the drug coming from Cochin China, and in an amount of 0.1 per cent. It is probably a decomposition product of either brucine or strychnine.

Strychnine ($C_{21}H_{22}O_2N_2$) was discovered by Pelletier and Caventou in 1818, in both the nux vomica and the bean of St. Ignatius. It generally constitutes a little less than one-half of the total alkaloids. For account of its chemical properties see *Strychnina.* For valuable practical information about the yield of the alkaloids, extracts, etc., by E. L. Patch, see *Proc. A. Ph. A.,* 1891, 91; also *P. J.,* 1889, 341; *P. J.,* 1890, 493.

Brucine ($C_{23}H_{26}O_4N_2$) was discovered by Pelletier and Caventou, first in the bark in combination with gallic acid, and subsequently, associated with strychnine in the form of igasurates, in the nux vomica and in the bean of St. Ignatius. It is a dimethoxy-strychnine. It may be separated from strychnine by virtue of the lesser solubility of its oxalate in dehydrated alcohol or of its hydriodide in water, or by the insolubility of strychnine chromate in water. Brucine is crystallizable from alcohol, the crystals then containing $4H_2O$. It is without odor, but of a permanent, harsh, very bitter taste; is sparingly soluble in water; very soluble in alcohol, whether hot or cold; it dissolves in 4 parts of chloroform, 440 parts of ether, 60 parts of benzene, and 120 parts of petroleum benzin. It is permanent in the air. The hydrated crystals melt at 105° C., and sublime at 204° C., while the anhydrous base melts at 178° C. changing color, and depositing carbon. It forms crystallizable salts with acids.

Concentrated nitric acid produces with brucine or its salts an intense crimson color, which changes to yellow by heat, and upon the addition of stannous chloride becomes violet. A test for brucine, given by Stanislas Cotton, consists in adding to a warm solution of brucine (from 40° to 50° C.) in nitric acid, a concentrated solution of sodium thiosulphate. The mixture first becomes violet, and then passes to green when the alkaline salt is in excess. (*J. P. C.,* 1869.) These reactions serve to distinguish brucine from strychnine, and, if produced with the latter alkaloid, evince the presence of the former. According to Larocque and Thibierge, auric chloride produces, with solutions of the salts of brucine, precipitates at first milky, then coffee-colored, and finally chocolate-brown. (*Journ. de Chim. Méd.*, 1842.) Chlorine water produces with solution of brucine a rose color, due to the formation of *dichlor-brucine.* This is a reddish-brown, hygroscopic powder. (*A. Pharm.*, 1886, 934.) A *dinitro-brucine,* $C_{23}H_{24}(NO_2)_2N_2O_4$, has also been obtained by the action of nitrogen trioxide upon the brucine in alcoholic solution. According to the analyses of Shenstone and Dragendorff, the bark of the nux vomica contains brucine, with a trace of strychnine, while in the leaves Hooper found only brucine. (*P. J.*, 1890, xxi.)

Brucine may be procured, in a manner essentially the same as that in which strychnine is procured from nux vomica, with this difference, that the alcoholic extract obtained from the precipitate produced by lime or magnesia should be treated with oxalic acid, and subsequently with a mixture of rectified alcohol and ether, which takes up the coloring matter, leaving brucine oxalate. This is decomposed by magnesia, and the brucine is separated by alcohol, which by spontaneous evaporation yields it in the state of crystals. Prescott (*Organic Analysis,* 1887, p. 458) gives two methods for the separation of strychnine from brucine, first, by the use of alcohol of 0.97 sp. gr., which easily dissolved brucine, but has very slight solvent power upon strychnine; second, by Dunstan and Short's method with potassium ferrocyanide. This method has been reported upon by Holst and Beckurts (*Ph. Centralh., N. F.* 1887, p. 119), who find that if the hydrochloric acid solution containing mixed alkaloids is not too dilute, on the addition of potassium ferrocyanide the whole of the strychnine will be precipitated as ferrocyanide, while the brucine salt will remain in solution.

The estimation of strychnine in the presence of brucine is most conveniently effected by exposing the mixed alkaloids to the action of diluted nitric acid, which destroys brucine very rapidly while having no appreciable action on strychnine; this method is used in the British official assay process.

Dunstan and Short (*P. J.*, 1883, xiv, 1025) found in the nux vomica seeds, but more abundantly in the pulp surrounding them, a glucoside *loganin,* $C_{25}H_{34}O_{14}$.

Loganin is present in the pulp to the amount of 4 or 5 per cent. and is contained in small quantity also in the seeds. It was obtained by exhausting the pulp with a mixture of chloroform and alcohol (100:25). The exhaustion was effected in an apparatus for hot repercolation. The percolate, on cooling, deposited crystals, which when recrystallized a number of times from alcohol, and finally from absolute alcohol, were obtained pure. Loganin is easily soluble in water and alcohol, less soluble in ether, chloroform, and benzene. Its aqueous solution is not precipitated by any of the alkaloidal reagents. Its most characteristic reaction is found in its behavior with concentrated sulphuric acid. A very small quantity of loganin, when gently warmed with a few drops of concentrated sulphuric acid, yields a fine red color, which, on standing, develops into a deep purple. By boiling with dilute sulphuric acid, loganin is resolved into glucose (reducing Fehling's solution) and a body for which the name *loganetin* is proposed. This substance, like loganin, gives the characteristic reaction with sulphuric acid, but the purple color does not develop so rapidly. Loganetin is soluble in water and alcohol, less soluble in ether, carbon disulphide and chloroform. (*P. J.*, 1884, p. 1025.)

In addition to these constituents, there are present a yellow coloring matter, a fixed oil, gum, starch. a small quantity of wax, and several earthy phosphates. The unsaponifiable portion of the oil was identified as a mixture of phytosterins. (*A. Pharm.*, 1912, p. 398.) F. Meyer (*In. Dis.*, St. Petersburg, 1875) investigated the fatty oil, and found it to consist of the glycerides of capric, caprylic, caproic, butyric and palmitic acids. (*A. J. P.*, 1874, 405.)

Other species of *Strychnos* contain the poisonous alkaloids, and may some time become a commercial source of them. *Bidara laut* of the Indian bazaars, believed to be obtained from *S. ligustrina* Blume has been analyzed by Russow, who found the wood to contain 2.26 per cent. and the bark 7.38 per cent. of brucine without strychnine. Henry G. Greenish found in the wood and bark respectively of *S. colubrina* L. 0.96 per cent. and 5.54 per cent. of mixed alkaloids; the same analyst obtained from false Angustura bark (*S. Nux-vomica*), young bark 3.10 per cent., old bark 1.68. (*P. J.*, 3d sér., ix, 1014.) According to Bernelot-Moens, the dry seeds of the *S. Tieute* Lesch. contain 1.469 per cent. of strychnine, with a trace of brucine. (*A. J. P.*, 1866, p. 506.) From the seeds of *Strychnos Rheedii* C. B. Clarke, W. R. Dunstan obtained a yield of 0.06 per cent. of brucine and no strychnine. (*Imp. Inst. Rep.*, 1901–1902.) The Congo poison known as *Cupua Apus,* according to Vinci (*A. I. P. T.*, xx), is produced from the *Strychnos Kipapa* Gilg. The bark of the root contains 6 per cent. of strychnine and the wood 0.1 per cent. From the seeds of *Strychnos cinnamomifolia* Thw., native to Ceylon, India, G. R. A. Short obtained a yield of 2.231 per cent. of brucine and 0.342 per cent. of strychnine (*P. J.*, 1924, 97).

Strychnos quadrangularis Hill. yields "*Ipohaker*" or Malayan arrow- poison. *S. Gaultheriana* Pierre yields *Hoangnan bark* which is used in eastern countries as a remedy for leprosy. *Strychnos Nux-blanda* Hill. of Burma produces seeds which contain neither strychnine nor brucine and are devoid of bitterness. According to A. W. Hill this species differs from *S. Nux-vomica* in the long calyx segments, the larger, abruptly acute leaves, larger fruits with more numerous seeds, the latter having a felty-white surface, without the satiny luster of genuine nux vomica seeds (*Kew Bull.*, 1917, p. 121).

Igasuric acid has been regarded as erroneously named, and investigators have stated that it was malic acid and tannic acid, while G. Sander (*A. Pharm.*, 1897, 133) believes that the acid found in nux vomica, heretofore known as igasuric acid, is *caffeo-tannic acid.*

Uses.—The medicinal and toxic properties of nux vomica are those of its alkaloid. (See *Strychnina.*) The belief held by some physicians that it acts more favorably as a bitter upon the stomach has only this much of justification—namely, that it is more slowly absorbed, and therefore acts locally somewhat more persistently.

BRUCINE.—On account of the difficulty of separating strychnine from brucine, it has been found by physiologists difficult to determine the exact action upon the human organism of the pure alkaloid. It was formerly taught that brucine closely resembled strychnine in its physiological action, except that it was less poisonous and that it was depressant to the peripheral sensory nerves. Dickson and Harvey (*P. J.*, 1908, lxxxi, p. 367), however, experimenting with a chemically pure brucine, reach the conclusion that its dominant action is a paralysis of the peripheral motor nerves, and that the convulsive action which is the characteristic effect of strychnine is almost entirely absent in the case of brucine. According to the observation of Mays, brucine is an active paralyzant to the sensory nerves and a 5 or 10 per cent. solution applied to the mouth causes local anesthesia. He has used it for the relief of *pruritus.* Burnett also asserts that a 5 per cent. solution is a valuable local anodyne in inflammations of the external ear.

Dose, of nux vomica, one to four grains (0.065–0.26 Gm.).

OLEA
OILS

These are liquid or solid substances, unctuous to the touch and characterized by inflammability. They are divided into two classes, the *fixed* and the *volatile,* because distinguished, as their names imply, most readily by their different behavior on the application of heat.

OLEA FIXA. *Fixed Oils.*

Oleo Pingua; Fats, Fatty Oils; Huiles Graisses, Huiles fixés, *Fr.;* Fette, Fette Oele, *G.;* Olios, *It.;* Aceites, *Sp.*

These are sometimes termed *fatty oils,* because they constitute in part the vegetable and animal fats. The distinction between liquid and solid fats is for the most part a physical one only, as they contain the same chemical compounds, although in relatively different proportions. The fatty oils, though existing in greater or less proportion in various parts of plants, are mainly derived commercially from the fruit, and, as a rule, are most abundant in the dicotyledonous seeds. They are obtained either by submitting the bruised seeds to pressure, or by boiling them in water, and skimming off the oil, as it rises to the surface. When pressure is employed, it is customary to prepare the seeds for the press by exposing them to a moderate heat, so as to render the oil more liquid and thus enable it to flow out more readily. Another mode of extracting certain oils is by extraction with one of the immiscible solvents, ether, carbon disulphide, carbon tetrachloride, or petroleum benzin being used. Fixed oils may be clarified and decolorized by subsidence, by filtration through animal charcoal, fuller's earth, kaolin, or diatomaceous earth, cellulose and asbestos filters are often used, and on the large scale, for separating mechanical impurities, centrifugal machines like those employed for milk. Some oils are given a preliminary treatment with sulphuric acid which is later removed by neutralization with alkali. Fixed oils containing stearin or palmitin are likely to deposit these fats in cold weather, leaving the olein in a liquid condition. The olein may be separated by expression and filtration in the cold.

Hydrogenated Fats and Oils.—A class of solid fats has appeared upon the market which are produced by a process known as hydrogenation, which is carried out commercially by bringing liquid fats into intimate contact with metallic catalyzers (finely divided nickel is usually employed), at elevated temperatures (160°–200° C.). Under these conditions the unsaturated members of the fatty acid series which are usually liquid and are represented by oleic acid, become converted into the solid members of the series, exemplified by stearic acid which is a saturated acid. Several commercial products made in this way are largely used for culinary purposes.

Some fixed oils, in drying, lose their fluid and oily character, and are converted into a transparent, yellowish, flexible solid. These are called "drying oils." Most fixed oils especially when not quite pure or entirely free from moisture, become rancid, acquiring an acrid and an unpleasant odor. This change is usually accompanied by the liberation of free fatty acids. Oils which have become rancid may sometimes be restored by treatment with weak alkalies and subsequent washing and drying.

The fixed oils are insoluble in water, but by the agency of certain factors are capable of forming mixtures with water which are called emulsions. (See *Emulsa.*) They are in general very sparingly soluble in alcohol, but readily dissolved by ether. By the aid of heat they are enabled to dissolve sulphur and phosphorus. The stronger acids effect the hydrolysis of fixed oils under certain conditions, giving rise, among other products, to oleic, palmitic and stearic acids. They are saponified by various alkalies. The compounds which the fatty acids form with potassium and sodium are the common detergent soaps, although strictly speaking, a soap is the combination of a fatty acid with any metal or base. (See *Sapo* and *Eplastrum Plumbi.*) The fixed oils also serve as good vehicles for various metallic bases and subsalts, which form soaps to a certain extent soluble in the oil, and thus become less irritant to the tissues. The fixed oils dissolve many of the alkaloids, the volatile oils, resin, and some other proximate principles of plants. The alkaloids are more readily dissolved in them by being first combined with oleic acid, the oleates being more soluble than the alkaloids themselves. According to Buignet, fixed oils, with very few exceptions, are indifferent to polarized light; of all those used in medicine, the only exceptions are the liver oils of the ray and dog fish, which have a very feeble lævorotatory power, and castor oil, which is decidedly dextrogyrate.

It is very likely that, with the exception of castor oil, whose rotatory power is due to the asymmetric carbon atom of the ricinoleic acid, the rotatory power is not due to the glycerides themselves but to small proportions of optically active substances such as cholesterol. (Lewkowitsch, *Chem. Analysis of Oils, Fats and Waxes,* p. 121.)

The fixed oils, whether animal or vegetable, in their natural state consist in most cases of at least two or three distinct constituents, one liquid at ordinary temperatures, and the other two solid or semi-solid. The liquid is a distinct proximate principle called *olein;* the more solid principles consist of *stearin* and *palmitin,* the former being found most largely in animal and the latter in vegetable oils or fats, and the two in most cases existing together in the same oil. The substance formerly known as *margarin* is now generally recognized to be a mixture of palmitin and stearin. As the most frequent of these proximate constituents of the fixed oils, and existing in many different oleaginous substances, olein, palmitin, and stearin merit a special notice. Preliminarily to their individual consideration, it will be proper to refer to their nature and composition generally.

These three substances, *olein, palmitin,* and *stearin,* together with *butyrin, caprin,* and other minor fat principles, are glycerides; that is, esters or salts of the triatomic alcohol glycerol, $C_3H_5(OH)_3$, and of the several fatty acids, oleic, palmitic, stearic, etc., all of which are monobasic acids. The three mentioned glycerides have the following composition:

Olein (triolein), $C_3H_5(OC_{18}H_{33}O)_3$
Palmitin (tripalmitin), $C_3H_5(OC_{16}H_{31}O)_3$
Stearin (tristearin), $C_3H_5(OC_{18}H_{35}O)_3$

There are also mixed glycerides exemplified by the following formula:

$$\underset{\text{(oleopalmitostearin)}}{C_3H_5}\begin{cases} OC_{18}H_{33}O \\ OC_{16}H_{31}O \\ OC_{18}H_{35}O \end{cases}$$

When these substances, or oils composed principally of them, are treated with alkali with the aid of heat, decomposition takes place, which may be illustrated as follows:

$$C_3H_5(OC_{18}H_{33}O)_3 + 3NaOH = C_3H_5(OH)_3 + 3NaOC_{18}H_{33}O$$

that is, olein is decomposed by sodium hydroxide into glyceryl hydroxide, or glycerin, and sodium oleate, or a sodium soap.

The waxes differ from the fats proper in being esters of the higher monatomic alcohols like *cetyl alcohol,* $C_{16}C_{33}.OH$, and *myricyl alcohol,* $C_{30}H_{61}.OH$, instead of being glycerides. The fatty acids present are partly palmitic and stearic, but more largely still higher ones, like *cerotic acid,* $C_{27}H_{54}O_2$.

Other fatty acids represented in fixed oils may be grouped as follows: (1) Saturated fatty acids, including *butyric acid,* $C_4H_8O_2$; *valeric acid,* $C_5H_{10}O_2$; *caproic acid,* $C_6H_{12}O_2$; *caprylic acid,* $C_8H_{16}O_2$; *capric acid,* $C_{10}H_{20}O_2$; *lauric acid,* $C_{12}H_{24}O_2$; *myristic acid,* $C_{14}H_{28}O_2$; *arachidic acid,* $C_{20}H_{40}O_2$. The first few members of the above list are known as the volatile fatty acids, which serve as the basis for the determination of what is known as the Reichert-Meissl number. (2) Unsaturated acids (Oleic Acid series) including: *crotonic acid,* $C_4H_6O_2$; *angelic* and *tiglic* (*tiglinic*) *acids,* $C_5H_8O_2$; *hypogeic acid,* $C_{16}H_{30}O_2$; *erucic acid,* $C_{22}H_{42}O_2$; *linoleic acid,* $C_{18}H_{32}O_2$, which gives to certain oils the peculiar "drying" properties.

Olein. Elain. Liquid Principle of Oils.—It is extremely difficult to obtain olein pure. Being in most oils associated with the solids stearin and palmitin, it must be separated by pressure and other mechanical means, which separation is not always perfectly effected. As ordinarily procured, therefore, olein contains more or less dissolved palmitin or stearin, or both. In this somewhat impure state it is obtained either by the agency of alcohol or by expression. When one of the oils, olive oil, for example, is dissolved in boiling alcohol, the solution, on cooling, deposits the palmitin and stearin, still retaining the olein, which it yields upon evaporation. The other method consists in compressing one of the solid fats, or one of the liquid oils rendered concrete by cold. Olein is a liquid of oily consistence, congealing at – 6° C., colorless when pure, with little odor and a sweetish taste, insoluble in water, soluble in boiling alcohol and ether. Its formula, as already stated, is $C_3H_5(OC_{18}H_{33}O)_3$, being an oleate of the triad radical *glyceryl,* C_3H_5. By reaction with nitric acid, or, under the influence of nitrous acid fumes, olein is converted into a deep yellow, butyraceous mass. If this be treated with hot alcohol, a deep orange-red oil is dissolved, and a peculiar fatty matter remains, called *elaidin.* This is white, crystalline, fusible at 34° C., insoluble in water, readily soluble in ether, and appears to be isomeric with olein. It is the product which gives the firm consistency to citrine ointment. It is resolved by saponification with the alkalies into *elaidic acid* and glycerin.

Palmitin.—Palmitic acid occurs in the more liquid fats, such as palm oil and cocoa-nut oil, as well as in butter and human fat, as glyceride, while in spermaceti and some forms of wax it is combined with monatomic alcohol radicals. Palmitin is the *palmitic acid glyceride,* or *glyceryl tripalmitate.* It is best obtained from palm oil.

Stearin.—This exists abundantly in tallow and other animal fats. Pure stearin may be obtained by treating the press cake from lard, free from olein, by cold ether so long as anything is dissolved. The palmitin is thus taken up, and stearin remains. Another method is to dissolve suet in heated oil of turpentine, allow the solution to cool, submit the solid matter to expression in unsized paper, repeat the treatment several times, and finally dissolve in hot ether, which deposits the stearin on cooling. This is concrete, white, opaque in mass, but of a pearly appearance as crystallized from ether, pulverizable, fusible at 66.5° C., soluble in boiling alcohol and ether, but nearly insoluble in those liquids cold, and quite insoluble in water. It consists of glyceryl and stearic acid (see *Acidum Stearicum*) in combination as a glyceride, $C_3H_5(OC_{18}H_{35}O)_3$, and has been formed synthetically by heating a mixture of these two materials to 280° to 300° C.

Commercially the fixed oils are frequently sold under the names "summer pressed" and "winter pressed." These were once really seasonal designations, as an oil pressed during the warmer months would contain more dissolved stearin and would consequently congeal or cause a deposit when chilled, while an oil pressed during cold weather would remain transparent at low temperatures, and thus winter pressed oils were more satisfactory for lubricating purposes and commanded a higher price. Artificial refrigeration now makes it possible to make either grade of oil at any season of the year, although the former designations "summer pressed" and "winter pressed" are still commercially used.

The fixed oils are liable to certain spontaneous changes, which have been investigated by Pelouze and Boudet. It appears from their researches that the oils are accompanied, in the seeds which contain them, with principles which act as a ferment and cause the oils to resolve themselves spontaneously into the several fatty acids which they afford on saponification, and into glycerin; that is, become rancid. This change takes place in the seeds as soon as the cells containing the oils are broken, so as to permit the contact of the oil with the fat splitting or lipolytic enzyme. The decomposition of fats by the action of enzymes has been made a working method capable of technical application, by Connstein, Hoyer and Wartenburg. The enzyme contained in the castor oil bean has been found best adapted for this. An emulsion of fats, water, 10 per cent. of ground castor oil beans and a small amount of free acid are used, when the decomposition proceeds rapidly. As rancidity in fats renders them altogether useless in pharmacy, and as it is not always readily discoverable by the senses in its earlier stages, it becomes desirable to possess a test by which it may be detected. Such a test is to be found, according to Thos. B. Groves, in potassium iodide, which is rapidly decomposed by the new principles developed, and the orange-brown discoloration produced by the liberation of the iodine indicates the existence of rancidity, and the degree of that discoloration, approximately, the extent of the change. The alteration of color is said by Groves to be plainly perceptible when only one-twentieth of rancid fat is present. The presence of water in a fatty oil favors the production of rancidity.

It is also extremely important to be able to protect fats against this change. The complete exclusion of air, light, and moisture—and, when in relation to air this may not be entirely practicable, the destruction by heat of the enzyme by which the decomposition is often originated—will go far to effect this object; but it would often be very inconvenient, if not impossible, to carry these measures into complete effect, and hence the discovery of substances which may have the effect of retarding, if not wholly preventing, these fermenting processes, is very desirable. This preservative effect has been known and practically used many years. Thus, benzoin rubbed up with fats is well known to preserve them long against rancidity, and benzoinated lard, made by extracting ten per cent. of benzoin with melted lard, is one of the official preparations, and the buds of the poplar (*Populus nigra*) are perhaps still more effectual, as, according to Deschamps, lard impregnated with their virtues will keep good indefinitely. In the French Codex the poplar buds are employed in the *Pommade de Bourgeon de Peuplier,* in which 8 parts of the dried buds are used to 40 parts of the ointment, consisting of lard impregnated with the virtues of several narcotic substances, the fresh narcotic plants being boiled with lard until all their water is evaporated, and the buds afterwards digested in the strained liquid for twenty-four hours.

The adulteration of the fixed oils may be effected in several ways—by admixture with the fatty oil of substances distinctly foreign to the fats, and by adding a cheaper or inferior oil of the same identity or closely related to one of greater value. In the former case we may have the addition of paraffin wax, ceresine, mineral oils, neutral tar oils, resin oils, resin, and waxes. Of these, the first three are entirely unsaponifiable, resin oils contain but small quantities of saponifiable substances, waxes are partly saponifiable, and resin almost completely saponifiable. The determination of unsaponifiable matter is therefore of great importance. The common method for this is to saponify the suspected sample with alcoholic potassium hydroxide and then to shake out the unsaponifiable matter with ether or petroleum ether. From this solution, on evaporation, will be obtained the mineral, resin, or tar oils that may have been present. For these there are appropriate tests elsewhere noted. In case a cheaper oil or fat has been added for the purpose of adulterating a more valuable one, we must be guided by the determination of certain constants, such as those mentioned below by Cowley, or by the indication of certain qualitative color tests. The constants referred to are much more to be depended upon in such a case.

R. C. Cowley (*P. J.*, 1897, 331) regards the following as the most important determinations in examining fats and fixed oils. 1. Specific gravity. 2. Melting and solidifying points. 3. Melting and solidifying points of fatty acids. 4. Behavior with solvents. 5. The Hehner value. 6. The Reichert-Meissl value. 7. The saponification value. 8. The iodine value. To these have been added during recent years: 9. The refractive index. 10. The acetyl number. 11. The temperature rise with sulphuric acid (Maumené number).

CLASSIFICATION.

The following scheme of classification of the fixed oils, both liquid and solid (Allen, *Com. Org. Anal.*, 3d ed., vol. ii, Part I, pp. 88–102), gives a general view of their essential characters, points of difference, etc.

I. Olive Oil Group. *Vegetable Non-drying Oils.*—The oils of this group solidify on treatment with nitrous acid or mercuric nitrate, but do not lose their power of producing a greasy stain on paper, however long they may be exposed to the air. Their density varies from 0.914 to about 0.920, and hence is less than that of Groups III, IV, and V. Their viscosity is notably greater than that of the drying oils.

This group includes almond oil (from *Amygdalus communis* L.), peach oil (from kernels of *Prunus Persica* Stokes), apricot oil (from kernels of *Prunus Armeniaca* L.), oil of ben (from *Moringa oleifera* Lam.), earth nut oil (from *Arachis hypogæa* L.), and olive oil (from *Olea europæa* L.).

II. Rape Oil Group.—The oils of this group are all derived from seeds of the family *Cruciferæ.* They are non-drying but less distinctly so than the oils of Group I. They show higher saponification values, higher iodine absorption and less solid elaidins than Group I.

This group includes Colza oil and rape seed oil (from *Brassica campestris* L., *B. napus* L. and other species); oil of black mustard (from seeds of *Brassica nigra* Koch.); oil of white mustard (from seeds of *Sinapis alba* L.).

III. Cotton Seed Oil Group.—The oils of this group occupy a position intermediate between the vegetable non-drying and the true drying oils (Groups I and IV). In density they somewhat exceed the oils of Group I, but are lighter than those of Groups IV and V. They form more or less elaidin on treatment with nitrous acid or mercuric nitrate, but do not become wholly solidified. On the other hand, they undergo more or less drying on exposure to the air, but not so markedly as the oils of Group IV.

This group includes beech nut oil (from *Fagus sylvatica* L.), cotton seed oil (from *Gossypium* species), hazel nut oil (from *Corylus Avellana* L. see *Proc. A. Ph. A.*, 1893), sesame or teel oil (from *Sesamum indicum* L.), sunflower oil (from *Helianthus annuus* L.), camelina oil (from *Myagrum sativum* L.), cress seed oil (from *Lepidium sativum* L.), and maize oil (*Corn Oil*).

IV. Linseed Oil Group. *Vegetable Drying Oils.*—These oils are not solidified by treatment with nitrous acid or mercuric nitrate, but become gradually converted into solid masses or varnishes, by exposure to the air. In density the oils of this group vary from about 0.923 to 0.937, and hence are distinctly heavier than the non-drying oils and than most of the oils of Group III. On the other hand, they are lighter than the oils of Group V. The fluidity of the drying oils is also much higher than that of the non-drying oils.

This group includes niger seed oil (from *Guizotia oleifera* DC.), hemp seed oil (from *Cannabis sativa* L.), linseed oil (from *Linum usitatissimum* L.; *L. perenne* L.), poppy seed oil (from *Papaver somniferum* L.), Scotch fir seed oil (from *Pinus sylvestris* L.), tobacco seed oil (from *Nicotiana Tabacum* L.), walnut oil (from *Juglans regia* L.), weld seed oil (from *Reseda Luteola* L.), and soya bean oil (from *Glycine Max* Merr.).

V. Castor Oil Group.—The oils of this group are distinguished from those of Groups I, II, III, and IV, by their very high density and viscosity. They are also remarkable for their ready solubility in alcohol, and their marked purgative properties. In their drying characters and behavior with the elaidin test they resemble the oils of the cotton seed oil group. Both castor and croton oil are miscible in all proportions with glacial acetic acid.

This group includes castor oil (from *Ricinus communis* L.), croton oil (from *Croton tiglium* L.), Japanese or Chinese wood oil (from seeds of *Aleurites cordata* Steud.), boiled linseed oil, blown oils (made by oxidation of rape seed, cotton seed, linseed, lard, and other oils).

VI. Palm Oil Group. *Solid Vegetable Fats.*—This group includes solid fats not containing notable quantities of glycerides of lower fatty acids. The densities for the melted fats at 98° and 99° C. are compared with the density of water at 15.5° C. taken as 1.000, and vary from 0.920 to 0.995.

This group includes palm oil (from fruit of *Elæis guineensis* Jacq.), cacao butter (from nuts of *Theobroma Cacao* L.), nutmeg butter (from nuts of *Myristica fragrans* Houttuyn), and shea butter (from seeds of *Bassia Parkii* G. Don) (*Butyrospermum Parkii* Kotschy).

VII. Cocoanut Oil Group. *Solid Vegetable*

Fats.—This group includes solid fats containing notable quantities of glycerides of lower fatty acids—that is, of acids distilling with more or less facility in a current of steam at 100° C. The group includes cocoanut oil (from the seeds of *Cocos nucifera* L. and *C. butyracea* L.), palm oil (from the kernels of the nuts from *Elæis guineensis* Jacq.), laurel oil (from fruit of *Laurus nobilis* L.), Japan wax (drupes of *Rhus succedanea* L.), myrtle wax (fruits of *Myrica cerifera* L.). For a description with constants of some of the rarer fixed oils belonging to the vegetable group, see papers by J. A. Wijs, *Ph. Ztg.*, 1903, 563; by Pancoast and Graham, *A. J. P.*, 1904, 70; and by Lewkowitsch, *P. J.*, 1904, 492.

VIII. Lard Oil Group. *Animal Oleins.*—This group includes those oils fluid at ordinary temperatures which are obtained from terrestrial animals. They resemble the whale or fish oils in their reaction with chlorine, but are not turned red or brown by boiling with caustic soda. On exposure to air and on treatment with nitrous acid or mercuric nitrate, they behave like the non-drying vegetable oils (Group I). This group includes bone oil, lard oil, tallow oil, and neat's-foot oil. For a paper by P. L. Simmonds on various animal oils, see *Bull. Pharm.*, 1893, 297, 344.

IX. Tallow Oil Group. *Solid Animal Fats.*—This group comprises oils that are solid or semisolid at ordinary temperatures. Their melting points vary somewhat, and are capable of permanent alteration. The group includes bone fat, butter fat, hog's lard, horse fat, beef tallow and mutton tallow.

X. Whale Oil Group. *Marine Animal Oils.*—This group comprises the various fluid oils obtained from fish and cetaceous mammals. They are distinguished as a class by their offensive fishy odor, by the brown color they assume when subjected to the action of chlorine, and by the reddish color which is produced on boiling them with a solution of caustic alkali. With sulphuric acid they give colorations varying from light red to purple or brown. The fish oils do not dry on exposure to air, and mostly yield but little elaidin on treatment with nitrous acid. The term *"train oil"* includes whale, seal, shark, cod, and all similar oils. Cod oil (from *Gadus morrhua* L. and allied species), cod liver oil (from the same), menhaden oil (from *Alosa menhaden* L.), porpoise oil (from *Delphinus phocæna* and allied species), seal oil (from various species of *Phoca*), shark oil (from *Squalus maximus* L. and allied species), and whale oil (from *Balaena mistecetus* L. and allied species) are all members of this group.

XI. Sperm Oil Group. *Liquid Waxes.*—The members of this group differ from all the fatty oils of previous classes in not being glycerides, consisting essentially of esters of monatomic alcohols of the ethylic series, in which respect they resemble the true waxes, but are fluid at ordinary temperatures. They are less dense than glycerides, they do not dry or thicken notably on exposure to air, but they yield solid elaidins on treatment with nitrous acid. The group includes sperm oil (from cranial cavities of *Physeter macrocephalus* L.), doegling or bottlenose oil, and dolphin oil.

XII. Spermaceti Group. *Waxes Proper.*—Spermaceti and the various waxes differ from the true fixed oils and fats in not forming glycerin when saponified, yielding instead certain of the higher monatomic alcohols, the identity of which varies with the nature of the wax. These alcohols are insoluble in water, and dissolve to but a limited extent in alcohol, but they are soluble in ether, chloroform, carbon disulphide, benzene, and petroleum benzin, and are apt to be mistaken for added paraffin wax when the substance is saponified and the soap extracted with a solvent.

This group includes beeswax (from honeycomb of various species of bees), Carnauba or Brazil wax (from the leaf-coverings of *Copernicia cerifera* Mart.), Chinese wax or Pela wax (produced by a species of *Coccus* which punctures the branches of certain trees), myrtle wax from fruits of *Myrica cerifera*), Ocuba wax (from *Myristica sebifera* Sw.), palm wax (from bark of *Ceroxylon andicola* Humb. of the Cordilleras) and spermaceti (deposits from the oil found in the cranial cavities of the sperm whale, *Physeter macrocephalus* L.). Wool fat, which consists largely of cholesterol, belongs to this group.

When oils are decomposed by heat they emit vapors of *acrolein*—which is *allyl aldehyde*, CH_2CHCHO—a highly volatile liquid resulting from the decomposition of glycerin well known for its irritating effects on the eyes and nostrils. Exposed to a red heat, in closed vessels, they yield, among other products of the destructive distillation, a large quantity of combustible and illuminating gases, among which ethylene and acetylene are readily recognized. Heated in the open air, they take fire, burning with a bright flame, and producing water and carbon dioxide. When kept in air-tight vessels, they remain unchanged for a great length of time, but exposed to the atmosphere they absorb oxygen and undergo change.

Effervescent Oils.—K. Dieterich recommends oils and fats which have been supersaturated with carbon dioxide and introduced by him under the name of "effervescent oils." (See *Proc. A. Ph. A.*, 1900, 494.) Under the influence of carbon dioxide, compounds which are easily split with the fatty acids are produced, which, particularly in the case of cod liver oil, permit the more complete absorption of the oil than is the case with oil not treated with carbon dioxide. The latter, moreover, acts as a preservative of the oils and renders them more palatable, destroying the unpleasant taste of cod liver oil, and to a certain extent also that of added medicaments, very materially. The absorbability of carbon dioxide is, however, not the same in all oils. Cod liver oil is capable of absorbing the largest quantity, castor oil the smallest, while olive oil stands intermediate. (*Ph. Centralh.*, 1901, 485.)

OLEA VOLATILIA. [*Olea Destillata.*]

Volatile Oils.

Olea Ætherea, Ætherolea; Ethereal Oils, Essential Oils, Distilled Oils; Huiles Volatiles, Huiles Essentielles, Huiles Distillées, Essences, *Fr.;* Flüchtige Oele, Aetherische Oele, *G.;* Essenze, *It.;* Esencias, Aceite volatil, *Sp.*

These are sometimes called *distilled oils,* from the mode in which they are usually procured; sometimes *essential oils,* from the circumstance that they possess, in a concentrated state, the organoleptic properties of the plants from which they are derived. The word *essence* is used in some countries to designate the volatile oils themselves, but in America this word has unfortunately been largely applied to the alcoholic solutions of the volatile oils, usually called the *spirits,* and the word *soluble essence* has been used to describe hydroalcoholic solutions of volatile oils which possess the property of mixing clear with water.

The term *Ætherolea* is used in some countries to distinguish the volatile oils in general from those which are produced by destructive distillation, like oil of amber, oil of cade, oil of tar, etc., which are given the collective name *pyrolea* (pyroligneous oils).

They exist in most odoriferous vegetable tissues, sometimes pervading the plant, sometimes confined to a single part; in some instances contained in distinct cells, and partially retained after desiccation, in others formed upon the surface, as in many flowers, and exhaled as soon as formed. Occasionally two or more are found in different parts of the same plant. Thus, the orange tree produces one oil in its leaves, another in its flowers, and a third in the rind of its fruit. In a few instances, when existing in distinct cells, they may be obtained by pressure, as from the rind of the lemon and orange; but they are generally obtained by steam distillation. (See page 733.) Some volatile oils, as those of bitter almond and mustard do not pre-exist in the plant issues but are produced by a chemical reaction which takes place between certain constituents in the presence of moisture. (See these oils for further details.)

The volatile oils are usually colorless when freshly distilled, or at most yellowish, but some are brown, red, green, or blue. There is reason, however, to believe that in most instances the color depends on foreign matter dissolved in the oils. Septimus Piesse succeeded, by the fractional distillation of certain volatile oils, in separating a blue liquid, which, by repeated rectification, he has obtained quite pure. In this state it has the sp. gr. 0.910, and a fixed boiling point of 302.3° C., and yields a dense blue vapor having peculiar optical properties. He named this principle *azulene,* and believed that upon it depends the blueness of volatile oils wherever existing. The yellowness of the oils he ascribed to the resin resulting from their oxidation, the green and brown colors to a mixture of azulene and resin in various proportions. The formula of azulene he gave as $C_{16}H_{26}O$. (*Chem. News,* 1863.) Gladstone named this blue coloring constituent *cæruleïn,* and stated that it contains nitrogen and is colored green by acids and alkalies.

Azulene was later investigated by Sherndal, who assigns to it the formula $C_{15}H_{18}$, which places it in the class of hydrocarbons. He states that it yields a dihydrosesquiterpene, $C_{15}H_{23}$, upon reduction and believes it to be related to alpha gurjunene, $C_{15}H_{24}$, a tricyclic compound existing in gurjun balsam.

The volatile oils have a strong odor, resembling that of the plants from which they were procured, though generally less agreeable. Their taste is hot and pungent, and, when they are diluted, is often gratefully aromatic. The greater number are lighter than water, though some are heavier; their sp. gr. varies from 0.847 to 1.17. They vaporize at ordinary temperatures, diffusing their peculiar odor, and are completely volatilized by heat. When distilled alone, they nearly always undergo partial decomposition. Heated in the open air, they take fire and burn with a bright flame attended with much smoke. Almost all of them are optically active, and advantage may sometimes be taken of this property to detect adulterations of one of these oils with another. The refractive index is another physical constant that is being studied in connection with volatile oils, but the accumulation of data is not yet sufficiently large to give the factor much value as yet. Exposed at ordinary temperatures, some of them absorb oxygen, assume a deeper color, become thicker and less odorous, and are ultimately converted into resin. This change takes place most rapidly under the influence of light. Before the alteration is complete, the remaining portion of oil may be recovered by distillation.

It is said that volatile oils which resinify and assume a turpentine odor, can be kept indefinitely by adding sodium bisulphite in the proportion of 50 grains to 1 pound. (*Pract. Drug.,* 1920, xxxix, 36.) They can also be preserved by the addition of 5 per cent. of a fixed oil, such as cotton-seed or olive oil.

CLASSIFICATION

The volatile oils are sometimes hydrocarbons, although with these are frequently associated alcohol- or ketone-like bodies called *camphors,* and products of oxidation known under the general name of resins, and undoubtedly formed from the hydrocarbons. Phenols, aldehydes, esters, ethers, and sulphides are also represented. The hydrocarbons are generally known as *terpenes,* from oil of turpentine, which is taken as a type. *Olea ætherea sine terpeno* is the name proposed by Schweissinger for concentrated volatile oils made so by the removal of the non-fragrant hydrocarbon, and representing from two to thirty volumes of the ordinary essential oils. Thus, one volume of the concentrated oil represents two volumes of the oils of anise, cassia, fennel, ginger grass, mentha crispa, mentha piperita, cloves, sassafras, and star anise; two and one-half volumes of the oils of bergamot, caraway, and lavender; four volumes of cumin and rosemary; five volumes of thyme; six volumes of coriander; eight volumes of calamus; ten volumes of absinthe; twenty volumes of juniper; thirty volumes of angelica, lemon and orange. It is asserted that these concentrated oils are more permanent, more soluble in alcohol and in water, have a finer odor, and are of constant composition, thus enabling the specific gravity and boiling point to be used as tests of purity. They should be kept in the dark. (*Ph. Centralh.*, 1888, No. 25. Under the name of *"terpeneless volatile oils,"* similar products can now be found in the market especially for use in perfumery and in the manufacture of flavoring extracts; they are undoubtedly superior to the ordinary volatile oils in odor and strength, but are not medicinally equivalent.

Wallach, to whom much of our knowledge on volatile oils is due, divides the hydrocarbons into classes, as follows:

1.—**True terpenes,** of the formula $C_{10}H_{16}$, of which there are two main groups: (*a*) the *terpane* group, uniting with two molecules of haloid acid or four atoms of bromine; this group includes *limonene, dipentene, sylvestrene, terpinolene, terpinene, thujene,* and *phellandrene,* and its members boil between 175° and 185° C.; (*b*) the *camphane* group, uniting with one molecule of haloid acid or two atoms of bromine; this group includes *pinene, bornylene, camphene,* and *fenchene,* and its members boil between 151° and 161° C.

2.—**Hemiterpenes,** of the formula C_5H_8, such as *isoprene.*

3.—**Polyterpenes,** such as *cedrene, cubebene, cadinene,* etc., of the formula $C_{15}H_{24}$ (*sesquiterpenes*); *colophene,* of the formula $C_{20}H_{32}$; and *caoutchouc,* of the formula $(C_{10}H_{16})_x$.

Hydrocarbons other than those of the terpene class, or derivable from them, occur very sparingly in the natural oils. Thus there is of the paraffin series of saturated hydrocarbons, *heptane,* C_7H_{16}, occurring in the oil from the *Pinus sabiniana,* or California *digger pine,* and solid hydrocarbons of the same series in oil of rose, and probably in oils of wintergreen and sweet birch. Of the benzene series there is a single representative in *cymene,* $C_{10}H_{14}$, found in the oils of the *Thymus* and *Monarda* species.

In addition to these naturally occurring hydrocarbons, there is a class of artificially prepared hydrocarbons known as *hydroterpenes,* such as dihydrodipentene from dipentene, menthene and carvomenthene from menthol and carvone.

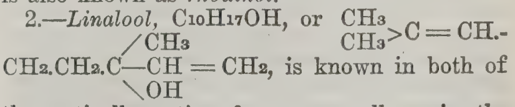
The terpenes in general are practically insoluble in water, but soluble in alcohol, ether, chloroform, benzene, petroleum benzin, and the fixed and volatile oils.

Many of the essential oils, however, owe their essential character and their value to other constituents than hydrocarbons. We shall briefly notice the most important of these either describing them or referring to other places in the text where they are already described, and shall then give a classification of the commonly known essential oils based upon the character of the most important compounds present in them.

In adition to the terpenes already mentioned, the chemical constituents of the volatile oils may be divided into seven groups as follows:

I. Alcohols and Their Esters.—This is an interesting group of open chain, unsaturated alcohols, which, with their esters and aldehydes, play a very important part in the composition of many essential oils. It is the geraniol, linalool and citronellol group.

1.—*Geraniol,* $C_{10}H_{17}OH$, or $\begin{matrix}CH_3\\CH_3\end{matrix}\!>C=OH.$-$CH_2.CH_2.C\begin{matrix}\diagup CH_3\\ \diagdown CH.CH_2OH\end{matrix}$, is a colorless liquid of a pleasant rose geranium odor, boiling at 229° to 230° C., under ordinary pressure, and at 129° C., under a pressure of 16 mm. Its specific gravity is about 0.881 and its refractive index 1.478. It is optically inactive. By careful oxidation with chromic trioxide it yields its aldehyde, citral, and by heating it in an autoclave with water to 200° C., it is partly converted into its isomer, linalool. It is a monatomic, primary, open chain alcohol, and is the principal constituent of true geranium (pelargonium) oil, as well as of the so-called *"Turkish geranium oil,"* or *oil of palmarosa.* It is a constituent of rose oil, of citronella oil and in very small proportions of a number of other oils. Of the esters of geraniol the most important is the *geranyl acetate.* This is a fragrant oil of specific gravity 0.917, boiling at from 128° to 129° C., under a pressure of 16 mm. It occurs naturally in several essential oils, and can be made artificially by the action of acetic anhydride upon geraniol. Commercial geraniol is also known as *rhodinol.*



2.—*Linalool,* $C_{10}H_{17}OH$, or $\begin{matrix}CH_3\\CH_3\end{matrix}\!>C=CH.$-$CH_2.CH_2.C\begin{matrix}\diagup CH_3\\ -CH=CH_2\\ \diagdown OH\end{matrix}$, is known in both of the optically active forms as well as in the inactive. It is a liquid having a pleasant odor, and boils under normal pressure at about 198° C., and at from 86° to 87° C. at 14 mm. pressure. Its specific gravity ranges from 0.868 to 0.877, and its refractive index is 1.463. It is a monatomic, tertiary, open chain alcohol, and is an essential constituent of oil of linaloe, and is found in the free state or as an acetic ester in oils of bergamot, coriander, lavender, neroli, etc. The most important of its esters is *linalyl acetate,* which occurs in many essential oils, as in oil of bergamot. It is an odoriferous liquid of the specific gravity 0.912, and boiling at from 105° to 108° C. at 11 mm. pressure. It is so prepared artificially, and the artificial ester is an important commercial article.

3.—*Citronellol*, $C_{10}H_{19}OH$, or $\left.\begin{matrix}CH_2\\CH_3\end{matrix}\right\rangle C—CH_2.CH_2.CH_2.CH\left\langle\begin{matrix}CH_3\\CH_2.CH_2OH\end{matrix}\right.$, is found in oil of rose and in Spanish geranium oil. It is an odoriferous oil, boiling at from 117° to 118° C., under a pressure of 17 mm.; specific gravity, 0.8565 at 17.5° C.; refractive index, 1.457. It is an open chain alcohol closely related to geraniol and is found in oil of rose, oil of geranium, etc. When obtained from oil of rose it is lævogyrate, while when obtained by reducing the aldehyde it is dextrogyrate; in most geranium oils both varieties exist.

A second group comprises the monocyclic alcohols, terpineol, which is unsaturated, and menthol, a saturated compound.

4.—*Terpineol*, $C_{10}H_{17}OH$, $\left.\begin{matrix}CH_3\\CH_3\end{matrix}\right>CH—COH.CH_2.CH_2.CH_2.CH.C—CH_3$, occurs in liquid and solid modifications, inactive, as well as in the two optically active, varieties. Besides occurring naturally it is made artificially by the dehydration of terpin hydrate, and is largely used in the perfume industry because of its lilac odor. It has a sp. gr. of 0.940 at 15° C. Its most important ester is the acetate, which occurs in cajuput and cardamom oils.

5.—*Menthol, menthyl alcohol,* $C_{10}H_{19}OH$, $\left.\begin{matrix}CH_3\\CH_3\end{matrix}\right\rangle CH–CH.CH_2.CHOH.CH_2.CH_2CH—CH_3$, is now official, and will be found described. Two of its esters are recognized as occurring with it in peppermint oil, menthyl acetate and menthyl iso-valerate. Of these the former is the more important. It is an oil having a penetrating odor, boiling at 224° C.

To a third group of compounds known as dicyclic, belongs:

6.—*Borneol*, $C_{10}H_{17}OH$, or $CH.CH_2.CH_2.CH_2.CH_3.C.CH_3.CH_2.CHOH.C—CH_3$. — This compound occurs naturally in both optically active modifications. It also occurs optically inactive. It forms crystalline masses, which, when quite pure, melt at 203° C. Borneol can be prepared artificially by reducing its ketone (camphor) with metallic sodium. In this case, however, there results a mixture of borneol and iso-borneol. Borneol forms a number of esters, of which *bornyl acetate* is the most important. This compound melts at 29° C., and has a specific gravity of 0.991 at 15° C. It is the characteristic constituent of the pine needle oils.

7.—*Nerol* is an alcohol discovered in oil of neroli. It is a stereo-isomer of geraniol. *Santalol,* so called, is found as an alcoholic constituent of oil of sandalwood. It has been given the formula $C_{15}H_{25}OH$, but is probably a mixture of several isomeric or closely related alcohols. It exists in two isomeric forms known as alpha and beta santalol. Alpha santalol has the following characters: b. pt. 300° C.; sp. gr. 0.979; ref. ind. 1.4990; opt. rot. +1° 6′. Beta santalol is as follows: b. pt. 309° C.; sp. gr. 0.989; opt. rot. –56°. Sabinol, $C_{10}H_{15}OH$, is a constituent of oil of savin. It is a secondary alcohol existing in several other oils. Its characters are as follows: b. pt. 208° C.; sp. gr. 0.9518; ref. ind. 1.4895; opt. rot. + 7° 56′.

Fenchyl alcohol, thujyl alcohol, and pulegol, all having the same empiric formula as geraniol, $C_{10}H_{17}OH$, do not occur naturally, but are produced from the respective ketones.

II. Aldehydes.—Of the alcohols just enumerated, only the first group are primary alcohols, and will yield aldehydes. Thus, from geraniol, there is obtained by oxidation, citral, the corresponding aldehyde, and from its isomer, linalool, the same.

1.—*Citral,* $C_9H_{15}COH$, or $(CH_3)_2C.CH.CH_2.CH_2.C(CH_3)CH.COH$.—Although at one time called *geranial,* this compound is now universally known as citral, which indicates its importance in the oils of the *citrus family.* It is obtained most abundantly from lemon grass oil by the aid of the bisulphite process. It is an oily liquid, boiling at from 228° to 230° C., under ordinary pressure, and at 110° C., under 12 mm. Its specific gravity is about 0.89 and its refractive index 1.49. It is optically inactive. Under the influence of alkalies, citral condenses with acetone with the elimination of water to form pseudo-ionone, $C_{13}H_{20}O$, which is converted into its isomer ionone by means of acids. Reduction with sodium produces the alcohol geraniol.

2.—*Citronellal,* $C_9H_{17}OH$, or $C(CH_3)_2CH.CH_2CH_2CH(CH_3)CH_2COH$, the aldehyde of citronellol, occurs in several essential oils, as in citronella oil. It is an oily liquid of characteristic odor; specific gravity 0.8768, refractive index 1.4481. It is dextrogyrate.

Of the class of aromatic aldehydes, there are found in essential oils, salicyl aldehyde, cumic aldehyde, benzaldehyde, and cinnamic aldehyde.

3.—*Salicyl Aldehyde,* $C_6H_4(OH)COH$.—This body is an oily liquid of aromatic odor, boiling at 196° C., and having a specific gravity of 1.172. It occurs in the oils of the several varieties of *Spiræa.* It can also be formed by the oxidation of its alcohol saligenin, or by the action of chloroform and potassium hydroxide on phenol.

4.—*Cumic Aldehyde,* $C_6H_4(C_3H_7)COH$.—This is p-isopropyl-benzaldehyde, and is found in several essential oils, as in cumin oil. It is an aromatic oil, having a specific gravity of 0.973, and boiling at 235° C.

5.—*Benzaldehyde,* $C_6H_5.COH$.—This is now official.

6.—*Cinnamic Aldehyde,* $C_6H_5.CH{:}CH.COH$.—This is described elsewhere (see under *Oleum Cinnamomi*).

Anisic Aldehyde, $C_6H_4(OCH_3)COH$ (oxymethyl-benzaldehyde), is a synthetic product used in artificial hawthorn perfume.

Piperonal or *Heliotropin,* $C_6H_3O_2CH_2COH$, is a synthetic product used in heliotrope perfume.

Santalal, $C_{14}H_{23}COH$, is found in sandalwood oil.

III. Ketones.—This class of chemical compounds is largely represented in essential oils. Of aliphatic saturated ketones there is only one fairly important representative.

1.—*Methyl-nonyl-ketone,* $CH_3.CO.C_9H_{19}$, which is found in oil of rue, is a liquid of strong odor, boiling at 225° C., and specific gravity 0.8295 at 17° C. It solidifies when cooled, and melts at 13° C.

Of aliphatic unsaturated ketones there is also one occurring naturally.

2.—*Methyl-heptenone,* $CH_3.CO.C_6H_{11}$, is found in lemon grass oil and other oils, and results from the oxidation of citral or the distillation of cineolic anhydride. It has a specific gravity of 0.853 at 20° C. and boils at 174° C.

A *methyl-amyl-ketone,* $C_5H_{11}COCH_3$, boiling at 151° C. and having a specific gravity of 0.837 at 50° C., is found as a minor constituent in oil of cloves.

The most commonly occurring ketones, however, belong to the cyclic compounds:

3.—*Carvone,* $C_{10}H_{14}O$, $CH_3C\left\langle\begin{matrix}CH—CH_2\\CO—CH_2\end{matrix}\right\rangle CH—C\left\langle\begin{matrix}CH_3\\CH_2\end{matrix}\right.$.—This compound, found in oils of caraway, fennel, spearmint and dill, is a colorless oil boiling at 225° C. and having a sp. gr. of 0.960 at 18° C. It is optically active, occurring in both forms. Its most interesting addition compound is that with hydrogen sulphide; this is obtained in crystals, decomposing with alcoholic potassium hydroxide and liberating pure carvone. When heated with glacial phosphoric acid, it is changed into the isomeric carvacrol, a phenol compound.

4.—*Pulegone,* $C_{10}H_{16}O$, $CH_3CH\left\langle\begin{matrix}CH_2—CO\\CH_2—CH_2\end{matrix}\right\rangle C{=}C\left\langle\begin{matrix}CH_3\\CH_3\end{matrix}\right.$.—This characteristic ketone of pennyroyal oil is a liquid boiling at 221° C. and having a specific gravity of 0.9323 at 20° C. An isomeric body, iso-pulegone, has been obtained artificially.

5.—*Menthone,* $C_{10}H_{18}O$, $CHCH\left\langle\begin{matrix}CH_2—CH_2\\CH_2—CO\end{matrix}\right\rangle CHCH(CH_3)_2$.—This occurs along with the corresponding secondary alcohol menthol, in oil of peppermint. It is an oily liquid boiling at 206° C., with a specific gravity of 0.897 at 15° C. By the action of oxidizing agents it can be converted into thymol, $C_{10}H_{14}O$.

To the class of dicyclic ketones belong the following isomeric bodies:

6.—*Camphor,* $C_{10}H_{16}O$,  .—This most important compound of the ketone class is official (see *Camphora*).

7.—*Fenchone,* $C_{10}H_{16}O$,  This ketone occurs as dextro-fenchone in oil of fennel, and as lævo-fenchone in oil of thuja. When purified, it forms an oil of camphoraceous odor, boiling at 193° C., and having a specific gravity of 0.9465 at 19° C.

8.—*Thujone,* $C_{10}H_{16}O$, $CH_3—CH\left\langle\begin{matrix}CO—CH_2\\CH—CH_2\end{matrix}\right\rangle C—CH\left\langle\begin{matrix}CH_3\\CH_3\end{matrix}\right.$.—This ketone is found in oils of thuja, tansy, wormwood and sage, and is identical with the bodies formerly known as *tanacetone* and *salvone.* It is an optically active liquid, boiling at from 200° to 203° C. and having a specific gravity of 0.9126 at 20° C.

A more complex ketone yet to be noted is:

9.—*Irone,* $C_{13}H_{20}O$, $(CH_3)_2C\left\langle\begin{matrix}CH(CH{:}CH.CO.CH_3)CH.CH_3\\CH{:}CH—\end{matrix}\right\rangle CH_2$.—The characteristic constituent of orris oil, to which also the violet odor is due, is irone. It is an oil almost insoluble in water, but readily soluble in alcohol, boiling at 144° C. at 16 mm., and having a specific gravity of 0.939 at 20° C. In the attempt to effect the synthesis of irone, Tiemann and Krüger obtained an isomeric body, *ionone,* from citral, which is now used as the artificial violet odor.

IV. Acids and Their Esters.—While esters of several of the fatty acids, both saturated and unsaturated, are found in the essential oils, the compounds are not so distinctive or characteristic, that they require mention here. Some of the esters have been already described under the appropriate alcohols, see geraniol, linalool, etc. Of esters of aromatic acids there are several of importance, however, comprising the most valuable constituents of the oil in which they occur. These include Methyl Salicylate, Methyl Anthranilate, Benzyl Acetate, Linalyl Acetate, Geranyl Acetate, Bornyl Acetate, Menthyl Acetate, Bornyl Valerate, Geranyl Tiglate, most of which are described under their alcohol constituent.

1.—*Methyl Salicylate* is the chief constituent of the oils of wintergreen and sweet birch. It is now official (see *Methylis Salicylas*).

2.—*Methyl Anthranilate* (*Methyl o-amidobenzoate*), $C_6H_4(NH_2)COOCH_3$.—This is the odoriferous constituent of neroli oil. It is an oil solidifying at low temperatures in crystals melting at 24.5° C., and boiling at 127° C. at 11 mm. Its specific gravity is 1.163 at 26° C. It is strongly fluorescent and has a powerful grape-like odor. It is used in imitation grape flavors.

V. Phenols and Phenol Ethers.—This is an important class largely represented in the volatile oils. Of monatomic phenols there are:

1.—*Chavicol* (para-allyl-phenol), $C_6H_4(OH)$-C_3H_5.—This occurs in the *oil of Chavica Betle,* and is a colorless liquid having a strong odor and a specific gravity of 1.035 at 20° C., boiling at 237° C. Still more abundantly formed in nature is its methyl ether, which is:

2.—*Methyl-chavicol,* $C_6H_4(OCH_3)C_3H_5$.—This occurs in the oils of anise, star anise, sweet-basil, bay, etc. It is also known as solid anethol or as *estragol* from its occurrence in *estragon* (*tarragon*) oil, from *Artemisia dracunculus.* It is a colorless liquid of an anise-like odor, boiling at from 215° to 216° C., having a specific gravity of 0.972 and a refractive index of 1.522.

3.—*Anethol,* $C_6H_4(OCH_3)C_3H_5$, is the methyl ether of p-propenyl-phenol, and isomeric with methyl-chavicol. It can be formed from the latter by heating it with alcoholic potassium hydroxide. It is the most abundant constituent of the oils of anise, star anise and fennel. It forms white scales having a specific gravity of 0.786 at 25° C., melting at 21° C., and boiling at 232° C. It is also known as *iso-estragol.*

4.—*Thymol* (*methyl-propyl-phenol*), $C_6H_3.CH_3.(OH)C_3H_7$ 1:3:4.—This is one of the best known of the phenols occurring in volatile oils. As it is official its description will be found under *Thymol.*

5.—*Carvacrol* (methyl-propyl-phenol), $C_6H_3.CH_3(OH)C_3H_7$ 1:2:4.—This important phenol, occurring in oils of marjoram and savory, is isomeric with thymol. It is a thick oil, solidifying at 0° C. and boiling at 236° C. It can be prepared artificially by heating carvone, an isomeric ketone, with phosphoric acid or by heating camphor with iodine.

Of diatomic phenols and their ethers, there are the following:

6.—*Eugenol,* $C_6H_3.OH.OCH_3.C_3H_5$ 4:3:1, is the methyl ether of allyl-dioxybenzene. It occurs in the oils of cloves, allspice, bay, Ceylon cinnamon and cinnamon leaves. It is now official.

7.—*Methyl-eugenol,* $C_6H_3.(OCH_3)_2.C_3H_5$, is found together with eugenol in oil of bay. It has a specific gravity of 1.041 at 11° C. and boils at 248° C.

8.—*Iso-eugenol* is the methyl ether of propenyl-dioxybenzene, and is produced from eugenol when the latter is heated with alcoholic potassium hydroxide. It is used in the manufacture of artificial vanillin.

9.—*Chavibetol,* $C_9H_8(OCH_3)OH$, is another isomer of eugenol, and occurs with chavicol in oil of betel leaves.

10.—*Safrol,*  $C_6H_3\genfrac{}{}{0pt}{}{O}{O}\!\!>CH_2.C_3H_5$, is the methylene ether of allyl-dioxybenzene. It is found quite largely in the oils of sassafras, camphor, etc. It was official in the U. S. P. VIII and is described in Part II.

11.—*Iso-safrol* is the methylene ether of propenyl-dioxybenzene, and is produced from safrol by heating the latter with alcoholic potassium hydroxide. It is used in the manufacture of *piperonal* (artificial heliotropin).

12.—*Thymohydroquinone dimethyl-ether,* $C_6H_2.(OCH_3)_2.CH_3.C_3H_7$, constitutes the bulk of the oil of arnica root. It is a liquid distilling at from 248° to 250° C.

Of triatomic phenols and their ethers, the representative is:

13.—*Asarol,* $C_6H_2(C_3H_5)(OCH_3)_3$.—This is the trimethyl ether of propenyl-trioxybenzene. It forms the solid constituent of the oil of *Asarum europæum,* and occurs in prisms melting at 61° C., and boiling at from 295° to 296° C. It has also been made synthetically.

Of tetratomic phenols and their ethers, there is also a representative, as follows:

14.—*Apiol,* $C_{12}H_{14}O_4$, $C_9H_6(OCH_3)_2O_2.CH_2$, is the dimethyl-methylene ether of allyl-tetroxybenzene. It occurs in two isomers—the apiol from oil of parsley and dill apiol from some varieties of oil of dill. Of these, the former is a crystalline solid melting at 30° C. and boiling at 294° C. and the latter is an oily liquid boiling at 288° C.

15.—*Diosphenol,* $C_{10}H_{16}O_2$ or buchu camphor as it is called, is a phenolic ketone. Its properties are as follows: m. pt. 83°; opt. rot. 0° b. pt. 232° (with decomposition). It has been prepared synthetically by several methods.

VI. Neutral Bodies, Oxides, etc.—One important compound of frequent occurrence in volatile oils has not been classified under any of the preceding groups, for the reason that it is relatively inert in a chemical way and is considered as an oxide of neither distinct acid or basic character.

1.—*Cineol* (*Eucalyptol*), $C_{10}H_{18}O$.—This is found in nature in large amounts in eucalyptus oil (hence the name "eucalyptol" sometimes given to it), in cajuput oil (hence the name of "cajuputol"), in lavender, wormseed, and other oils. It is now official under the name of *eucalyptol.*

VII. Sulphides and Sulphur Compounds.—Several of the volatile oils contain compounds of sulphur. Among the latter are:

1.—*Di-allyl disulphide,* $C_6H_{10}S_2$, is a constituent of oil of garlic and occurs in many oils belonging to the *Cruciferæ.* It is a liquid of very unpleasant odor, boiling at 140° C.

2.—*Allyl-isothiocyanate,* $C_3H_5.NCS$, is the principal constituent of the volatile oil of mustard. It is, however, a decomposition product of the glucoside potassium myronate, which breaks up under the influence of the ferment myrosin. The allyl thiocyanate can also be obtained artificially by distilling allyl iodide or bromide with alcoholic potassium thiocyanate. This artificial product is largely sold in place of the natural oil. It is a liquid having a very unpleasant odor, boiling at 151° C., and having a specific gravity of 1.017 at 10° C.

Vinyl sulphide, $(C_2H_3)_2S$, is found in a variety of garlic.

Butylisothiocyanate, $CH(CH_3)C_2H_5NCS$, is found in oil of horseradish, *acrynyl isothiocyanate,* C_7H_7ONCS, is found in white mustard and *phenylethyl isothiocyanate,* $C_2H_4(C_6H_5)-NCS$, is found in oil of mignonette.

CLASSIFICATION.

Classification of the more commonly occurring volatile oils.—In considering the question of classifying the volatile oils, two methods of arrangement naturally suggest themselves, viz.: a classification according to the botanical natural orders to which they belong, and a chemical classification based on the most important chemical constituents of the oils themselves. While the first of these is the more readily made, it suffers from the disadvantage of being cumbrous and less readily understood except by the botanist. On the other hand, the second plan shows at a glance the sources of the valuable odoriferous and medicinally and technically important constituents for which the volatile oils are largely used. That it has not been generally adopted is no doubt due to the fact that many of the oils contain several different constituents of value, and it is therefore difficult to make an assignment of some of them to individual chemical groups. Any chemical system of classifying volatile oils must be either exceedingly complex and cumbersome or, if conciseness is attempted, there are too many inconsistencies and discrepancies. For instance, one of the favored methods of classification is to divide them into four groups, i.e., the terpenes, oxygenated oils, nitrogenerated oils, and sulphurated oils. If this be critically studied it is seen that oil of lemon, which is usually given as a typical example of the terpene class, owes its real identity and value to citral, an aldehyde present in only a very small proportion (less than 5 per cent.), and that oil of bitter almond, which is given as the example of the nitrogenated class, owes its classification in this respect only to the incidental presence of hydrocyanic acid, which is frequently removed from the oil, especially when it is used for flavoring purposes. Moreover the sulphurated class contains only one important member, which the oxygenated class is the repository of over 90 per cent. of oils of diversified character.

It is therefore more suitable to follow the foregoing outline adding such explanatory matter and examples as will serve to make it intelligible and valuable for either study or reference purposes. It is believed that the chemical classification adopted here will be found to have practical value for reference.

Group I.—*Oils containing mainly Terpenes and Sesquiterpenes.*

Oil of Cedarwood; cedrene and cedrol (an oxygenated constituent).
 Copaiba Balsam; caryophyllene.
 Cubeb; cadinene and cubeb camphor (an oxygenated constituent).
 Dog Fennel; pellandrene.
 Fleabane; d-limonene.
 Galbanum; pinene and cadinene.
 Ginger; sesquiterpene and phellandrene.
 Hemp; cannabene and other terpenes.
 Hops; humulene and tetrahydrocymene.
 Myristica; terpenes and myristicol (an oxygenated constituent).
 Orange; limonene with small amount of citral and citronellal (both oxygenated constituents).
 Turpentine; pinene and sylvestrene.

Group II.—*Oils containing mainly Alcohols and their esters.*

a. Aliphatic saturated alcohols:
 Oil of Heracleum; octyl alcohol and octyl ester.

b. Aliphatic unsaturated alcohols:
 Oil of Bergamot; linalool and linalyl acetate.
 Coriander; linalool and d-pinene.
 Geranium; geraniol and geranyl esters.
 Lavender; linalyl acetate and geraniol.
 Lime; linalyl acetate and limonene.
 Linaloes; linalool and geraniol.
 Petit Grain; linalool and linalyl acetate.
 Rose; geraniol and citronellol with esters.

c. Monocyclic and dicyclic alcohols:
 Oil of Angostura; galipol, galipene, and cadinene.
 Fir Cones; bornyl acetate and terpenes.
 Golden Rod; borneol and bornyl esters.
 Juniper Berries; Juniper camphor and cadinene.
 Ledum; ledum camphor.
 Lovage; terpineol.
 Mace; myristicol.
 Patchouli; patchouli camphor and cadinene.
 Peppermint; menthol and menthone.
 Pine Needles; bornyl acetate and terpenes.
 Rosemary; borneol and bornyl acetate.
 Sandalwood; santalol and esters.
 Savin; sabinol and sabinyl acetate.
 Valerian; Borneol and bornyl esters.

d. Aromatic Alcohols and Esters:
 Oil of Jasmine; benzyl acetate and benzyl alcohol.

Group III.—*Oils containing Aldehydes as characteristic constituents.*

a. Aliphatic unsaturated aldehydes:
 Oil of Citron peel; citral and limonene.
 Citronella; citronellal and geraniol.

Lemon; Citral and citronellal (this oil might also properly be classed in Group I, as the terpenes constitute over 90 per cent. of the oils).
Lemon grass; citral, citronellal, and methyl-heptenone.
Verbena; citral.

b. Aromatic aldehydes:
Oil of Bitter Almond; benzaldehyde.
Cassia; cinnamic aldehyde.
Cinnamon; cinnamic aldehyde and eugenol.
Cumin; cumic aldehyde.
Meadow Sweet; salicyl aldehyde.

Group IV.—*Oils containing Ketones as characteristic constituents.*

a. Aliphatic saturated aldehydes:
Oil of Rue; methyl-nonyl-ketone.

b. Aliphatic unsaturated aldehydes:
Oil of Lemon grass; methyl-heptenone.

c. Monocyclic and dicyclic ketones:
Oil of Artemisia; thujone.
Camphor; camphor.
Caraway; carvone and limonene.
Dill; carvone and limonene.
Orris; irone.
Pennyroyal; pulegone.
Peppermint; menthone and menthol.
Sage; thujone with borneol and cineol.
Spearmint; carvone.
Tansy; thujone with borneol.
Thuja; thujone and fenchone.
Wormwood; thujone and thujyl alcohol.

Group V.—*Oils containing Esters.*

a. Aliphatic Acids:
Oil of Angelica; methyl-ethyl-acetic esters.
Calamus; heptylic and palmitic acid and esters.
Cardamom; acetic esters and cineol.
German Chamomile; caproic acid esters.
Roman Chamomile; butyric, angelic and tiglic esters.

b. Aromatic acid esters:
Oil of Neroli; o-amido-benzoic-methyl ester.
Sweet Birch; methyl salicylate.
Gaultheria; methyl salicylate.

c. Undetermined acids:
Oil of Celery; sedanolide and lactone.
Elecampane; alantic acid and lactone.

Group VI.—*Oils containing Phenols and Phenol Ethers.*

a. Monatomic phenols and their ethers:
Oil of Ajowan; thymol and cymene.
Anise; anethol and methyl-chavicol.
Betel; chavicol and methoxy-chavicol.
Fennel; anethol and fenchone.
Marjoram; carvacrol and linalool.
Savory; carvacrol, pinene, and cymene.
Star Anise; anethol, methyl-chavicol and safrol.
Sweet Basil; Methyl-chavicol and d-linalool.

b. Diatomic phenols and their ethers:
Oil of Arnica Root; thymohydroquinone dimethyl-ether.
Bay; eugenol, methyl-eugenol and methyl-chavicol.
Camphor; safrol, eugenol and camphor.
Cascarilla Bark; eugenol and terpenes.
Cinnamon Leaf; eugenol and cinnamic aldehyde.
Cloves; eugenol and sesquiterpene.
Pimenta; eugenol and sesquiterpene.
Sassafras; safrol and camphor.

c. Triatomic phenols and their ethers:
Oil of Asarum; asarol and methyl-eugenol.
Matico; asarol.

d. Tetratomic phenols and their ethers:
Oil of Parsley; apiol.

Group VII.—*Oils containing Neutral Bodies.*
Oil of Cajuput; cineol, terpineol and terpenyl acetate.
Eucalyptus; cineol, pinene, and aldehydes.
Laurel Leaves; cineol and pinene.
Myrtle; cineol, d-pinene and dipentene.
Wormseed; cineol and dipentene.

Group VIII.—*Oils containing Sulphur.*
Oil of Asafœtida; sulphides and pinene.
Garlic; diallyl-disulphide and allylpropyl sulphide.
Mustard; allyl-thiocyanate, allylcyanide and carbon disulphide.
Onion; allyl-propyl sulphide.

Properties.—Volatile oils are slightly soluble in water. Agitated with this fluid they render it milky, but the major portion separates upon standing, leaving the water impregnated with their odor and taste. This impregnation is more complete when water is distilled with the oils, or from the plants containing them. Trituration with insoluble powders, as talc, magnesium carbonate, kieselguhr, etc., renders them more easily soluble, probably in consequence of their minute division. The intervention of sugar also greatly increases their solubility, and affords a convenient method of preparing them for internal use. The hydrocarbon oils are scarcely soluble in diluted alcohol, and, according to De Saussure, the solubility of volatile oils generally in this liquid is proportionate to the oxygen which they contain. The volatile oils dissolve sulphur and phosphorus with the aid of heat, and deposit them on cooling. By long boiling with sulphur they form brown, unctuous, fetid substances, formerly called *balsams of sulphur.* They absorb chlorine, which converts them into resinous oxidation products and then combines with these. Iodine produces a similar effect. They are decomposed by the strong mineral acids, and unite with some organic acids. When treated with a caustic alkali, some of them are saponified or otherwise decomposed. Several of the metallic oxides, and various salts which easily part with oxygen, convert them into resinous oxidation products. The volatile oils dissolve many of the proximate principles of plant and animal tissues, such as the fixed oils and fats, resins, camphor, and many of the alkaloids when in the free state. Exposed to air and light, many of them absorb oxygen and become what are termed ozonized oils which possess oxidizing properties.

Adulterations.—The volatile oils are often sophisticated. Among the greater adulterations are fixed oils, resinous substances, chloroform, hydrocarbon oils, and alcohol, but the most dangerous are those made by mixing the pure oil with the cheaper volatile oils and terpenes and fractions from other oils like limonene. The presence of the fixed oils may be known by the permanent greasy stain which they leave on paper, while that occasioned by a pure volatile oil disappears entirely when exposed to heat. They may also in general be detected by their comparative insolubility in alcohol. Both the fixed oils and resins are left behind when the adulterated oil is distilled with water. If alcohol be present, the oil will become milky when agitated with water in a graduated tube, and after the separation of the liquids the water will occupy more space and the oil less than before. The following method of detecting alcohol was proposed by Beral. Put twelve drops of the suspected oil in a perfectly dry watch-glass, and add a piece of potassium about as large as the head of a pin. If the potassium remains for twelve or fifteen minutes in the midst of the liquid, there is either no alcohol present, or less than 4 per cent. If it disappears in five minutes, the oil contains more than 4 per cent. of alcohol; if in less than a minute, 25 per cent. or more. Borsarelli employs calcium chloride for the same purpose. This he introduces in small pieces, well dried and perfectly free from powder, into a small cylindrical tube, closed at one end, and about two-thirds filled with the oil to be examined, and heats the tube to 100° C., occasionally shaking it. If there is considerable proportion of alcohol, the chloride will be entirely dissolved, forming a solution which sinks to the bottom of the tube; if only a very small quantity, the pieces will lose their form, and collect at the bottom in a white adhering mass; if none at all, they will remain unchanged. (*J. P. C.,* xxvi, 429.) J. J. Bernoulli proposes as a test dry potassium acetate, which remains unaffected in a pure oil, but will be dissolved if alcohol be present, and form a distinct liquid. (See *A. J. P.,* xxv, 82.) Distillation, catching the first portion, and testing for alcohol by the iodoform reaction, will detect very small additions of alcohol. The adulterants most difficult of detection are the synthetic terpenes or alcohols or those occurring as by-products in some departments of the essential oil industry.

Sometimes volatile oils of little value are mixed with the more costly. The taste and odor afford in this case the best means of detecting the fraud. The specific gravity of the oils is rarely of any value as a test of purity.

The optical activity is one of the most valuable of the physical constants used in detecting adulteration and in determining the purity of volatile oils. Thus, the oils of juniper, lavender, and rosemary rotate the plane of polarization to the left, while American oil of turpentine rotates it to the right; and if this should be added to one of the other oils it lowers the optical activity and thus offers one means for its detection. Unfortunately, the French oil of turpentine, obtained from the *Pinus Maritima,* acts strongly in the opposite direction. But the very strength of its left-rotatory power might lead to its detection by the abnormal increase of this power which it would impart to the oils in question. Synthetic or artificial volatile oils are now largely manufactured. They vary greatly at times in their resemblance to the natural products. They will be considered under their respective titles elsewhere, a number having received official recognition.

Volatile oils may be preserved without change in small, well-stoppered amber-colored bottles, entirely filled with the oil, and secluded from the light.

They may also be preserved by mixing with them about 5 per cent. of a bland fixed oil which will remain undissolved when the volatile oil is added to alcohol and for which allowance must be made, of course, in the volume of the oil used in formulas, etc. (LaWall, *Proc. A. Ph. A.,* 1910, 1121.)

Manufacture.—Neither the U. S. nor Br. give any official method for distilling any of the volatile oils. Although some of these require peculiar methods for their proper separation most of the official volatile oils may be prepared by the general formula of the U. S. P. 1870: "Put the substance from which the Oil is to be extracted into a retort or other vessel suited for distillation, and add enough water to cover it; then distil by a regulated heat into a large refrigeratory. Separate the Distilled Oil from the water which comes over with it."

Under the general observations on the *Aquæ,* or *Waters,* will be found remarks upon the use of steam in preparing the Distilled Waters, which are to a considerable extent applicable also to the volatile oils.

The substances from which the volatile oils are extracted may be employed in either the recent or the dried state. Certain flowers, however, such as orange flowers and roses, must be used fresh, or preserved with salt or by means of glycerin, as they afford little or no oil after desiccation. Most of the aromatic herbs, also, as peppermint, spearmint, pennyroyal, and marjoram, are usually distilled while fresh. Dried substances, before being submitted to distillation, require to be macerated in water until they are thoroughly penetrated by this fluid, and to facilitate the action of the water it is necessary that, when of a hard or tough consistence, they should be properly comminuted by slicing, shaving, rasping, bruising or other similar mechanical operation.

The water which is introduced into the still with the substance answers the double purpose of preventing the decomposition of the vegetable matter by regulating the temperature, and of facilitating the volatilization of the oil, which, although in most instances readily rising with the vapor of boiling water, requires, when distilled alone, a considerably higher temperature, and is at the same time liable to be partially decomposed. Some oils, however, will not ascend readily with steam at 100° C., and in the distillation of these it is customary to use water saturated with common salt, which does not boil under 110° C. Recourse may also be had to a bath of strong solution of calcium chloride, or to an oil bath. Other oils, again, may be volatilized with water at a temperature below the boiling point, and, as heat exercises an injurious influence over the oils, it is desirable that the distillation should be effected at as low a temperature as possible. To prevent injury from heat, it has been recommended to suspend the substance containing the oil in a wire basket, or to place it upon a perforated shelf, in the upper part of the still, so that it may be penetrated by the steam, without being in direct contact with the water. Another mode of effecting the same object is to distil it *in vacuo*. Duncan stated that the most elegant volatile oils he had ever seen were prepared in this manner by Barry, the inventor of the process. The employment of steam heat also prevents injury, and the best volatile oils are now prepared by manufacturers in this way. Steam can be very conveniently applied to this purpose by causing it to pass through a coil of tube, of an inch or three-quarters of an inch bore, placed in the bottom of a common still. The end at which the steam is admitted enters the still at the upper part, and the other end, at which the steam and condensed water escape, passes out laterally below, being furnished with a stop-cock, by which the pressure of the steam may be regulated and the water drawn off when necessary. In some instances it is desirable to conduct the steam immediately into the still near the bottom, by which the contents are kept in a state of brisk ebullition. This method is used in the preparation of the oil of bitter almond. The same method is applicable to the preparation of distilled waters.

The quantity of water added is not a matter of indifference. An excess above what is necessary acts injuriously by holding the oil in solution when the mixed vapors are condensed, and if the proportion be very large, it is possible that no oil whatever may be obtained separate. On the contrary, if the quantity be too small, the whole of the oil will not be distilled, and there will be danger of the substance in the still adhering to the sides of the vessel and thus become burnt. Enough water should always be added to cover the solid material and prevent the latter accident. Dried plants require more water than the fresh and succulent. The whole amount of material in the still, should not exceed three-fourths of its capacity, as otherwise there would be danger of the liquid boiling over. The form of the still has an influence over the quantity of water distilled, which depends more upon the extent of surface than upon the amount of liquid submitted to evaporation. By employing a high and rather narrow vessel one may obviate the disadvantage of an excessive quantity of water. Sometimes the proportion of oil in the substance employed is so small that it is wholly dissolved in the water distilled, even though the proportion of the liquid in the still is not greater than is absolutely essential. In this case it is necessary to redistil the same water several times from fresh portions of the plant, until the quantity of oil exceeds the solvent power of the water. This process is called *cohobation*.

The more volatile of the oils pass with facility along with the steam into the neck of the common still, but some which are less volatile are apt to condense in the head and thus return into the still. For the distillation of the latter, a copper still should be employed having a very low head. As, after the distillation of any one oil, it is necessary that the apparatus should be thoroughly cleansed before being used for the preparation of another, it is better that the condensing tubes should be straight, rather than spiral as in the ordinary still. It should be recollected, moreover, that certain oils, such as those of anise and fennel, are rendered solid by a comparatively slight reduction of temperature, and that in the distillation of these the water employed for refrigeration should not be below 5.5° C.

The mixed vapors are condensed into a milky liquid, which is collected in a receiver, and, after standing for some time, separates into the oil and a clear solution of it, the former floating on the surface, or sinking to the bottom, according as it is lighter or heavier than water. The distillation should be continued so long as the liquid coming over has a milky appearance.

The last step in the process is to separate the oil from the water. For this purpose the *Florentine receiver* may be used. For illustrations of this, and other forms of receivers, for collecting and separating immiscible liquids, see Remington's *Practice of Pharmacy*, 6th edition, p. 250. This is a conical glass vessel, broad at the bottom and narrow towards the top, and very near its base furnished with a tubulure or opening, to which is adapted, by means of a pierced cork, a bent tube so shaped as to rise perpendicularly to seven-eighths of the height of the receiver, then to pass off from it at right angles, and near the end to bend downward. The condensed liquid being admitted through the opening at the top of the receiver, the oil separates, and, rising to the top, occupies the upper narrow part of the vessel, while the water remains at the bottom, and enters the tube affixed to the receiver. When the surface of the liquid attains in the receiver a higher level than the top of the tube, the water will necessarily begin to flow out through the latter, and may be received in bottles. The oil thus accumulates as long as the process continues, but it is evident that the plan is applicable only to the oils lighter than water. For the heavier oils, cylindrical vessels may be employed, to be renewed as fast as they are filled; but, as all the water cannot be removed by these plans, it is necessary to resort to some other method of effecting a complete separation. An instrument called a *separator* is usually employed for this purpose. It consists of a glass funnel, or a globular vessel, furnished with a stopper, and prolonged at the bottom into a very narrow tube. The lower opening being closed, the mixed liquids are introduced and allowed to stand until they separate. The orifice at the bottom is then opened, and, the stopper at the top being a little loosened, so as to admit the air, the heavier liquid slowly flows out, and may be separated to the last drop from the lighter, which floats above it. If the oil is heavier than the water, it passes out of the separator; if lighter, it remains within. According to George Leuchs, all oils obtained by distillation with water, even when perfectly clear, contain some water.

The water saturated with oil should be preserved for use in future distillations, as it can dissolve no more of the oil. One or more volatile acids are frequently found in the distilled water, as acetic, butyric, or valerianic, and Wunder has detected all three of these acids in the water distilled from chamomile flowers. (*J. Pr. Chem.*, lxiv, 499.) For an illustration of a cheap apparatus for distilling volatile oils by steam under slight pressure, see *Proc. A. Ph. A.*, 1894, 680.

When first procured, some volatile oils have a disagreeable somewhat empyreumatic odor, from which they may be freed by allowing them to stand for some days in vessels loosely covered with paper. They should then be filtered and introduced into small opaque bottles, which should be well stoppered so as to exclude the air. When altered by exposure to air, they may sometimes be restored to their original appearance and quality by agitation with a little recently heated animal charcoal, and the same method may be employed for freeing them from adhering water.

They may be administered upon a lump of sugar; or triturated with at least ten times their weight of sugar, forming *oleosaccharates*, which are then dissolved in water; or made into emulsions with water, sugar, and gum arabic. In making emulsions with volatile oils, it has been recommended first to dissolve them in one of the fixed oils, the oil of almond for example, and then to emulsionize the oleaginous solution with syrup and gum arabic. For 100 parts of water, 15 of the almond oil in which the volatile oil is to be dissolved, 10 of powdered gum arabic, and 25 of syrup may be taken. The following suggestions on preparing emulsions of the volatile oils may be useful. Oil of turpentine and other volatile oils, to be emulsionized in quantity, are most successfully treated by rubbing them with one-half their weight of powdered gum arabic, and, when intimately mixed, adding at once, with rapid trituration, water in the proportion of one and a half times the weight of the gum used. Such an emulsion is more permanent when a little fixed oil is used. The volatile oils are often kept dissolved in alcohol under the name of essences.

Enfleurage.—This term is applied by the French to the impregnation of fixed oils and fatty matters with the odors of certain sweet scented plants, such as jasmine, tuberose, and mignonette, the oils of which are so delicate and fugitive that they cannot well be separated by distillation. The process consists in exposing the fatty matter, placed in layers, in suitable frames, to the exhalations from the flowers, which are absorbed, and give their characteristic odor to the fat. Another plan is to expose alternate layers of the flowers, and of cotton impregnated with bland fixed oil, to the sun, and afterwards to express the oil from the cotton. (*A. J. P.*, xxix, 551.) The French sometimes give to the spirituous solutions made by extracting the odors from fats and oils with alcohol the name of *Essences.*

Uses.—While substances differing so widely in their source and in their chemical composition must manifestly exercise dissimilar effects upon the body, there are certain properties common to so many of the volatile oils that a word concerning the therapeutic effects of this group of principles may be in place. Practically all of the official volatile oils are more or less irritant; some of them only feebly so and some very actively so. By virtue of this action when taken into the intestinal tract they excite peristalsis and are therefore used for the expulsion of flatus in *colic* as well as to enhance the effect of cathartic drugs. Although the direct action of the volatile oils upon muscle tissue as shown by Gunn (*J. P. Ex. T.*, 1920, xvi, p. 39) is to relax rather than stimulate, Plant (*J. P. Ex. T.*, 1920, xvi, p. 311) has shown that when applied to the mucous membrane of the intestines, they increase both the tone and peristaltic contraction. That these effects are due to an action upon the sensory nerve endings is strongly indicated by the fact that they are abolished by local application of cocaine. He finds considerable variation in the carminative power of the volatile oils, the most powerful of these tested by him including mustard, cinnamon, peppermint and clove. In a subsequent paper (*J. P. Ex. T.*, 1923, xxi, p. 203) he reported that cinnamon water lessened the muscular contractions of the stomach, although it increased those of the intestines. It is probably also to this local irritant effect that their uses as expectorants, diaphoretics, and diuretics is to be attributed. A large number of them are powerful germicides and nearly all of them more or less antiseptic. The antibacterial property of the volatile oils has been investigated especially by Martindale (*Perfume and Essential Oil Record,* 1910, i, p. 266), by Gilmore (*P. J.*, 1910, p. 844), and by Peck (*J. A. M. A.*, 1899, xxxii, p. 6). According to Martindale the oil of origanum is twenty-five times as actively germicidal as phenol and the oil of cloves about 9 times; while Peck finds that the oil of cloves prevents the multiplication of bacteria when present in about 1 part to 1100. The following volatile oils are powerfully germicidal: origanum, thyme, cinnamon, cassia, cloves, bay, and sassafras. Of considerable disinfectant power but weaker than the preceding are: peppermint, eucalyptus, cajuput, bitter almond, sandal wood, spearmint and lavender. The following are feeble in their antibacterial properties: anise, bergamot, juniper, cade, and turpentine. Concerning most of the other oils figures are lacking. While the cost of the volatile oils precludes their use for many disinfectant purposes yet for others they are very valuable agents, especially are they employed for their antibacterial properties in the mouth and nose. Morel and Rochaix (*C. R. S. B.*, 1921, lxxxv, p. 861) found that the vapors given off at a temperature of 37° C. by some of the volatile oils had a feeble germicidal effect, but that none but the most sensitive bacteria were killed and these only after several hours.

OLEATA.

OLEATES

Oléates, *Fr.;* Oleate, *G.*

The *oleates* are a class of preparations which were introduced to the medical profession by John Marshall, F.R.S., in 1872. They are usually solutions of certain bases in oleic acid, and are made by triturating the solid substance with the oleic acid until it is dissolved. Whenever it is possible, the application of heat should be avoided, and it has been observed that the freshly precipitated oxides of the metals dissolve more readily than those which are old. The title oleate is probably the best that could be devised, although it must be understood that, as found in the Pharmacopœias, they are not pure chemical compounds, but merely compounds of the oxides or the alkaloids, as the case may be, with oleic acid dissolved in an excess of the latter or in a fixed oil.

Oleates may be made either by direct combination of the ingredients or by double decomposition. When made by the latter method, a good quality of oleic acid should be treated with the proper quantity of solution of sodium hydroxide, to saponify it, any excess of the alkali being neutralized with a little tartaric acid. This soap solution is preferably used diluted.

J. M. Good, in making the oleates of the alkaloids, proposes the use of sufficient oleic acid to dissolve the alkaloid and then diluting the solution with a bland fixed oil, such as almond oil. (*Proc. Missouri Pharm. Association*, 1891, p. 65.)

The *medicinal properties* of the oleates are, of course, dependent upon the base, so that these preparations may be considered the equivalents of the corresponding ointments, over which, however, they have certain advantages. They are much cleaner and more elegant in appearance. They seem to be more irritating than the ointments, and, unless diluted with an equal bulk of cottonseed, olive, or other bland oil, are, when applied with friction, likely to provoke a cutaneous eruption or even pustulation. Marshall recommends that they be applied with a brush, or gently spread over the part with the finger.

OLEATUM HYDRARGYRI. U. S. (Br.)

OLEATE OF MERCURY Oleat. Hydrarg.

Hydrargyrum Oleatum, *Br.;* Mercuric Oleate; Hydrargyrum Oleicum; Oléate de Mercure, *Fr.;* Oelsaures Quecksilber, Quecksilberoleat, Mercurioleat, *G.*

"Yellow Mercuric Oxide, in very fine powder, 25 Gm.; Oleic Acid, a sufficient quantity, to make 100 Gm.

"Mix the yellow mercuric oxide with 75 Gm. of oleic acid, warm the mixture to a temperature not exceeding 50° C., stir constantly for five minutes, and then continue the heat, stirring frequently until the mercuric oxide is dissolved. Add sufficient oleic acid to make the product weigh 100 Gm. and mix thoroughly. In the preparation of this Oleate avoid all contact with metallic utensils. Preserve Oleate of Mercury in tightly-closed containers, protected from light, and do not dispense it if globules of mercury are visible at the bottom of the container." *U. S.*

"Yellow Mercuric Oxide, 20 *grammes; Liquid* Paraffin, 5 *grammes;* Oleic Acid, 75 *grammes.* Triturate the Mercuric Oxide with the Liquid Paraffin until it is thoroughly subdivided; add the Oleic Acid with vigorous stirring. Heat the mixture to 50° C. triturating occasionally until combination is effected, and, when cool, a yellowish unctuous preparation is obtained." *Br.*

This oleate is now made with 25 per cent. of mercuric oxide; that of the British Pharm. contains 20 per cent. Water was used in this oleate in order to facilitate combination in the U. S. P. VIII, alcohol in the U. S. P. IX, but neither in the U. S. P. X.

If made from oleic acid which has been purified from the usual contaminations (palmitic and stearic acids), it is a clear yellowish liquid of a thick consistence and having the peculiar odor of oleic acid. As usually seen, however, it is of the consistence and appearance of petrolatum, due to the presence of small quantities of mercuric palmitate and stearate. (See *Acidum Oleicum.*) The formula of a normal oleate of mercury would be $(C_{18}H_{33}O_2)_2Hg$. Free oleic acid is intentionally present in this U. S. preparation, which is known frequently as "25 per cent. oleate of mercury." In making this preparation, care must be exercised in the selection of the oleic acid, and to avoid exceeding the degree of heat directed in the official process; indeed, our experience has been that it keeps better if made by the cold process—*i.e.*, by simply mixing the freshly precipitated yellow oxide with the oleic acid, and allowing them to stand at ordinary temperatures until the precipitate has dissolved. The British preparation (1898) was modelled after Shoemaker's process, but in the Br. Pharm., 1914, the mercuric oxide is triturated with liquid paraffin. The precipitated mercuric oleate is difficult to free from water, and is prone to change. In time, even with the best oleic acid that can be procured, some decomposition will take place, and metallic mercury will be found at the bottom of the containing bottle. The rapidity of the change will be in proportion to the impurities in the oleic acid and the degree of heat employed. Beringer's process, by the double decomposition of potassium oleate and mercuric nitrate, is commended by Edel. (See *West. Drug.*, 1894, 85.)

Uses.—This preparation may often be substituted with advantage for mercurial ointment, which it closely resembles in its medicinal properties; it has been asserted that it is more readily absorbed, and therefore more effective. Mercury oleate has been especially commended by Marshall in cases of *chronically inflamed joints,* and in *hordeolum, indurations after abscesses,* and various other forms of superficial local inflammations of a slow type; also in *sycosis, tinea, psoriasis, eczema,* and as a constitutional alterative in *hereditary syphilis.*

Dose, one-half to two drachms (2–8 Gm.) applied externally.

OLEORESINA ASPIDII. U. S. (Br.)

OLEORESIN OF ASPIDIUM Oleores. Aspid. [Oleoresin of Male Fern]

"Oleoresin of Aspidium yields not less than 24 per cent. of crude filicin." *U. S.* "Liquid Extract of Male Fern contains in 100 grammes not less than 20 grammes of filicin." *Br.*

Extractum Filicis Liquidum, *Br.;* Oleoresina Filicis, *Pharm.* 1870; Liquid Extract of Male Fern, Oil of Fern; Oleum Filicis Maris; Extrait de Fougère Mâle, *Fr. Cod.;* Extractum Filicis, *P. G.;* Farnextrakt, Wurmfarnextrakt, Wurmfarnöl, *G.;* Estratto de felce maschio etero, *It.;* Extracto etereo de helecho macho, *Sp.*

"Aspidium, recently reduced to coarse powder, 500 Gm.; Ether, a sufficient quantity. Place the aspidium in a cylindrical glass percolator provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with ether added in successive portions until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water bath, and, having transferred the residue to a dish, allow the remaining ether to evaporate spontaneously in a warm place, remote from a naked flame." *U. S.*

"Male Fern, in No. 20 powder, 1000 *grammes;* Ether, *a sufficient quantity.* Exhaust the Male Fern by percolation with the Ether; from the clear percolate recover the ether by distillation and finally evaporate on a water-bath until an oily extract remains. Specific gravity not less than 1.000. *Refractive index* at 40° C. not less than 1.490. Contains in 100 grammes not less than 20 grammes of filicin as determined by the following process." *Br.*

The requirement of the U. S. that not more than 15 per cent. of the oleoresin shall be insoluble in petroleum ether is directed against the presence of castor oil.

This is the only preparation of male fern which should be used; in its making aspidium which is green in color and recently collected should be employed. It is a thick, dark green liquid, having the odor of the fern and a nauseous bitter and somewhat acrid taste. It usually contains a granular deposit of crystalline *filicic anhydride,* often erroneously called *filicin* or *filicic acid,* which is regarded as an active ingredient and should not be separated. Wm. G. Greenawalt found both the liquid and the sediment effective tenicides, the sediment somewhat the more active. According to Hayes, when an absolutely dry root and an anhydrous ether (containing but little alcohol) of a specific gravity below 0.728 are used, the oleoresin remains clear. Oleoresin of male fern is sometimes found in the market containing noticeable proportions of copper, and in many cases it is colored green artificially.

Description and Physical Properties.—"A dark green, thick liquid, usually depositing a granular, crystalline substance, which must be thoroughly mixed with the liquid portion before use. Not less than 85 per cent. of the Oleoresin is soluble in purified petroleum benzin. Specific gravity: not less than 1.00 at 25° C. Preserve in well stoppered bottles." *U. S.*

Assay.—It is unfortunate that the U. S. and British Pharmacopœias both use the term "filicin" as indicative of the important principles of this drug, for the activity of the substance to which this name is applied in scientific literature (filicic anhydride) is very doubtful (see under *Aspidium*). The composition of the ethereal extraction—as in the official assay—is reputed to be about as follows: 100 parts of oleoresin contain 3.5 of filicic acid, 2.5 of flavaspidic acid, 6.00 of filicic nigrine, 5.00 of filmaron (by some believed to be the true active principle), 0.05 of albaspidin, 0.10 each of flavaspidin and aspidinol, and 5.00 of amorphous acids.

The official methods of standardization are as follows:

"Warm the Oleoresin on a water bath and stir until it is thoroughly mixed. Transfer about 5 Gm., accurately weighed, to a 200 cc. flask, dissolve in 40 Gm. of ether, add 100 Gm. of an aqueous solution of barium hydroxide (3 in 100), and shake vigorously for five minutes. Allow the liquids to separate, and filter off 86 Gm. of the aqueous fluid. Transfer this to a separator, add sufficient hydrochloric acid to produce a distinctly acid reaction, and extract with three successive portions of 30 cc., 20 cc., and 15 cc. of ether. Draw off and combine the ethereal solutions, filter, wash the filter with ether, evaporate, and dry the residue to constant weight at 100° C. This residue weighs not less than 0.96 Gm., corresponding to not less than 24 per cent. of crude filicin." *U. S.*

"Dissolve 5 grammes of the Liquid Extract in 40 millilitres of *ether,* transfer to a separator, add 100 grammes of *solution of barium hydroxide* and shake vigorously and continuously for five minutes. Allow the liquids to separate and filter off 86 grammes of the aqueous liquid. Acidify this with *hydrochloric acid* and extract with three successive portions of 30, 20, and 15 millilitres of *ether.* Filter the mixed ethereal solutions, wash the filter paper with *ether,* evaporate, dry the residue at 100° C. and weigh. It weighs not less than 0.8 gramme, equivalent to not less than 20 grammes of filicin in 100 grammes of the Liquid Extract. This Liquid Extract contains not less than 20 per cent. of filicin." *Br.*

The assay of oleoresin of aspidium is likely to give very discrepant results because of lack of homogeneity of the sample.

For therapeutic properties of this oleoresin, see *Aspidium.*

Dose, from one-half to one fluidrachm (1.8–3.75 cc.), administered in emulsion.

OLEORESINA CAPSICI. U. S.

OLEORESIN OF CAPSICUM Oleores. Capsic.

Oléorésine (Extrait éthéré) de Capsique, *Fr.;* Spanischpfeffer-Oelharz, Aetherisches Spanishpfeffer-extrakt, *G.*

"Capsicum, in coarse powder, 500 Gm.; Ether, a sufficient quantity. Place the capsicum in a cylindrical glass percolator provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with ether added in successive portions until the percolate measures 800 cc. Recover the greater part of the ether from the percolate by distillation on a water bath, and, having transferred the residue to a dish, allow the remaining ether to evaporate spontaneously in a warm place, remote from a naked flame. Then pour off the liquid portion, transfer the remainder to a glass funnel provided with a pledget of cotton, and, when the separated fatty matter (which is to be rejected) has been completely drained, mix the liquid portions.

"Oleoresin of Capsicum should meet the requirements of the following test: Dissolve 0.2 Gm. of the Oleoresin in 50 cc. of alcohol in a stoppered flask, dilute 0.1 cc. of the clear separated solution with 140 cc. of distilled water containing 10 per cent. of sucrose: five cc. of this dilution, swallowed at one time, will produce a distinct sensation of pungency in the mouth and throat of at least two out of three individuals. Preserve in well stoppered bottles." *U. S.*

One of the active principles of capsicum, called *capsaicin,* $C_9H_{14}O_2$, is very soluble in ether, and is wholly extracted in the process. Its precise nature has not been determined. Another principle, even still more pungent than *capsaicin,* is *capsicutin* which is also extracted by the official solvent in making this oleoresin. (See *Capsicum.*) After the concentration of the acetone solution, a solid fatty matter separates on standing, but a portion of fixed oil probably still remains. The preparation is a very thick liquid, capable, however, of being dropped, of a dark reddish-brown color, and, though opaque in mass, yet transparent in thin layers. It has not very decidedly the odor of capsicum, but to the taste is intensely pungent. W. C. Alpers found a capsicum which yielded 16 per cent. of oleoresin; the statement has been frequently made that 5 per cent. is the usual yield. (*M. R.,* 1896, 593.)

Uses.—It may be usefully employed to give locally stimulant properties to substances administered internally in a pilular form, in cases of *gastric insensibility* and excessive *flatulence,* and the relaxing type of serous *diarrhea.* One drop given three times a day has produced cystic irritation and strangury. It may be used also as a powerful rubefacient, in strengths of from one to two per cent., diluted with olive oil or soap liniment.

Dose, from one-fourth to one grain (0.015–0.065 Gm.).

Off. Prep.—Unguentum Capsici, *N. F.*

OLEORESINÆ

OLEORESINS

Oléo-résines, Extraits éthérés, *Fr.;* Oelharze, Aetherische Extrakte, *G.*

The oleoresins, as a class of preparations, were introduced into the U. S. Pharmacopœia at the revision of 1860, having been previously classed with the fluidextracts; only two were admitted to the U. S. X. Their peculiarity is that they consist of principles which, when extracted by means of ether, alcohol, or acetone, retain a liquid or semi-liquid state upon the evaporation of the menstruum. They are decidedly more potent than the fluidextracts because they retain none of the solvent, and differ from them also in not having a definite relation of strength to the drug. They consist chiefly, as their name implies, of oil, either fixed or volatile, holding resin and sometimes other active matter in solution. Their preparation is very simple, consisting in the exhaustion of the drug with ether by means of percolation, and the subsequent evaporation of the menstruum. In consequence of the great volatility of the solvent, it may in great measure be recovered by distillation, thus very materially diminishing the costliness of the process. It is proper not to continue the heat necessary for the recovery of the solvent by distillation until the whole of the solvent is driven over, lest, towards the close, a portion of the volatile matters also should pass, and the strength of the oleoresin be impaired. Hence in every instance the last portions of the menstruum are allowed to separate by spontaneous evaporation. Petroleum benzin and acetone have been proposed as a substitute for other solvents in these preparations, but are not at present officially sanctioned. It is difficult, if not impossible, to remove the last traces of this solvent without loss of volatile oil. Acetone replaced ether in most of the formulas of the U. S. P. VIII on account of economy, but as ether is again the cheaper solvent because of the use of denatured alcohol in its manufacture, it is again officially directed in the U. S. P. X.

OLEUM ABIETIS. Br.

OIL OF SIBERIAN FIR [Oil of Pine]

"Oil of Siberian Fir is the oil distilled from the fresh leaves of Abies sibirica, *Ledeb.*" *Br.*

Abies sibirica Ledeb. is a coniferous tree indigenous to Eastern Europe and Asia. It attains a height of 60 to 100 feet and possesses dark yellowish-green leaves and slender, cylindrical, brownish-yellow cones up to 3 inches long.

The oil which is distilled from the leaves is described as:

"Colorless or nearly so. Aromatic odor; taste pungent. Specific gravity 0.900 to 0.920; *optical rotation* −32° to −42°; *refractive index* at 25° C. about 1.474. Contains from 30 to 40 per cent. of *esters,* calculated as bornyl acetate, $C_{10}H_{17}C_2H_3O_2$." *Br.*

This is practically the same in its properties and uses as pine needle oil. (See *Oleum Pini Pumilionis.*)

OLEUM AJOWAN. Br.

AJOWAN OIL [Ptychotis Oil]

"Ajowan Oil is the oil distilled from the fruit of Carum Copticum, *Benth. and Hook. f.*" *Br.*

For description of the plant from which this oil is obtained, see *Ajowan,* Part II. The fruits resemble in size the fruits of the ordinary parsley and are of a grayish-brown color and have a tubercular surface with five prominent ridges to each mericarp. The odor and taste resemble that of thyme. These fruits yield from 4 to 6 per cent. of an agreeably aromatic volatile oil. Ajowan oil is "colorless, with an odor and taste resembling thyme. Specific gravity 0.910 to 0.930. *Optical rotation* + 1° to + 2°. When 10 millilitres with 100 millilitres of *solution of sodium hydroxide* in a flask with a narrow graduated neck are heated on a water-bath, well shaken, and allowed to stand, the uncombined oil, cooled to 15.5° C., measures not more than 6 millilitres (presence of not less than 40 per cent. of thymol)." *Br.*

This oil, besides containing thymol, contains a terpene and also the cyclic hydrocarbon, cymene.

The oil of ajowan is one of the most important commercial sources of thymol. Its medicinal virtues are due entirely to this ingredient.

Dose, one-half to five minims (0.03–0.3 cc.).

OLEUM AMYGDALÆ AMARÆ. U. S.

OIL OF BITTER ALMOND Ol. Amygd. Amar. [Bitter Almond Oil]

"The volatile oil obtained by maceration with water and subsequent distillation with steam from the dried ripe kernels (deprived of fixed oil) of *Amygdalus communis* Linné (Fam. *Rosaceæ*), or from other kernels containing amygdalin. The botanical source from which the Oil is derived must be stated on the label. Oil of Bitter Almond yields not less than 85 per cent. of benzaldehyde [C_7H_6O] and not less than 2 per cent. and not more than 4 per cent. of hydrocyanic acid [HCN]. Oil in which crystals have formed must not be dispensed. NOTE—This Oil is intended for medicinal use and neither it nor its solution should be used or sold for flavoring foods." *U. S.*

Oleum Amygdalarum (Amararum) Æthereum; Oleum Amygdalæ Volatile; Volatile Oil of Almond; Huile volatile d'Amande amère, *Fr. Cod.;* Essence d'Amandes amères, *Fr.;* Bittermandelöl, *G.;* Esencia de almendras amargas, *Sp.*

When bitter almonds are expressed, they yield a bland fixed oil, and the residuary cake, reduced to powder by grinding, and submitted to distillation with water, yields oil of bitter almond. This does not pre-exist in the almond, but is produced by the action of water upon the l-mandelonitrile glucoside contained in it, through the intervention of an enzyme called emulsin (see *Amygdala Amara*).

Much of the "bitter-almond oil" of commerce comes from apricot kernels.

Oil of bitter almond has a yellowish color, a bitter, acrid, burning taste, and the odor of the kernels in a high degree. It is heavier than water, soluble in alcohol and ether, according to Flückiger soluble in 300 parts of hot or cold water, and deposits, upon standing, a white crystalline substance consisting chiefly of benzoic acid.

Description and Physical Properties.—"A clear, colorless or yellow, strongly refractive liquid, having the characteristic odor and taste of benzaldehyde. When first prepared, the Oil is neutral to moistened litmus paper, but afterward develops an acid reaction, due to the formation of benzoic acid.

"The Oil is slightly soluble in water and is soluble in all proportions in alcohol and in ether. It forms a clear solution with 2 volumes of 70 per cent. alcohol, by volume. Specific gravity: 1.038 to 1.060 at 25° C. Optical rotation: varies from inactive to $+0° 10'$ in a 100 mm. tube at 25° C. Refractive index: 1.5428 to 1.5439 at 20° C. The Oil meets the requirements of the test for *heavy metals in volatile oils.* Rinse the interior surface of a well-cleaned, 1000 cc. beaker with distilled water, and pass the washings through a small filter until the addition of 1 drop of silver nitrate T.S. to a portion of the filtrate, acidulated with 1 drop of nitric acid, shows no turbidity. Place 3 or 4 drops of the Oil on a clean watch glass supported on a triangle, ignite, and immediately cover with the moistened beaker. Wash the products of combustion from the sides of the beaker through the washed filter with 10 to 20 cc. of distilled water, and acidulate the filtrate with 1 drop of nitric acid: the addition of 1 drop of silver nitrate T.S. produces no turbidity (*chlorinated products*). Add 10 drops of Oil of Bitter Almond to 5 cc. of alcohol, then add a small amount of zinc dust and 2 cc. of acetic acid, and boil the mixture for about ten seconds: no odor of phenylisocyanide develops after rendering the liquid strongly alkaline with sodium hydroxide T.S. and then adding a few drops of chloroform and heating (*nitrobenzene*). Preserve in small, well-stoppered, completely filled, amber-colored bottles, in a cool place, protected from light." *U. S.*

Besides benzaldehyde, it contains also hydrocyanic acid, with usually a small proportion of benzoic acid produced by oxidation of the aldehyde. The characteristic odor of this oil is due chiefly to the benzaldehyde and although slightly modified by the prussic acid. The U. S. provides assays for benzaldehyde and also for hydrocyanic acid.

Benzoic aldehyde is now made synthetically from toluene, C_7H_8. (See *Benzaldehydum.*) To prevent the formation of benzoic acid in oil of bitter almond, Schimmel & Co. recommended the addition of 10 per cent. of alcohol to the oil. Wm. A. Tilden (*P. J.*, 1866) has found that the introduction of a little fused calcium chloride into purified oil of bitter almond contributes to its preservation, probably by the absorption of the last traces of water contained in it.

Schimmel & Co. (*Semi-Annual Report,* April, 1893) state that an oil of high specific gravity should be carefully examined for benzo-nitrile, C_6H_5CN, which may form by condensation from benzaldehyde and hydrocyanic acid, and when distilled even *in vacuo* will decompose into the same components.

Nitrobenzene was at one time a frequent adulterant of oil of bitter almond. It may best be detected by the U. S. P. test given above, for additional tests see *U. S. D.*, 19th ed., p. 830–831.

Hager's test may be used quantitatively for the estimation of the amount of nitrobenzene present. Oil of bitter almond requires for solution sixteen to seventeen times its volume of 45 per cent. alcohol. Two cc. of the oil are agitated with 34 cc. of the 45 per cent. alcohol, and the mixture set aside. After the lapse of a day, the nitrobenzene (all but a trace which remains in solution) will be found collected at the bottom. An important indication of the presence of a sophistication is the cloudiness produced at the first moment. (*N. R.*, Oct., 1880.)

Assay for Benzaldehyde.—"Dissolve about 3 cc. of freshly redistilled phenylhydrazine in about 60 cc. of alcohol, and titrate 25 cc. of this solution, which must be freshly prepared, with half-normal hydrochloric acid, using 1 drop of methyl orange T.S. as indicator. To about 1 Gm. of Oil of Bitter Almond, accurately weighed, add another 25 cc. portion of the phenylhydrazine solution, and allow the mixture to stand thirty minutes. Add 1 drop of methyl orange T.S., and acidify the mixture by adding a measured excess of half-normal hydrochloric acid. Filter the mixture, and wash the precipitate with small portions of distilled water until the washings cease to redden moistened blue litmus paper. Then titrate the excess of hydrochloric acid in the combined filtrates with half-normal sodium hydroxide, and subtract the number of cc. of half-normal hydrochloric acid consumed from the number of cc. of half-normal hydrochloric acid used in titrating 25 cc. of the phenylhydrazine solution. The difference multiplied by 0.05304 gives the weight of benzaldehyde." *U. S.*

Assay for Hydrocyanic Acid.—"Dissolve 0.75 Gm. of magnesium sulphate in 45 cc. of distilled water, add 5 cc. of half-normal sodium hydroxide and 2 drops of potassium chromate T.S., and titrate the solution with tenth-normal silver nitrate to the production of a permanent reddish tint. Pour this mixture into a 100 cc. flask containing about 1 Gm. of Oil of Bitter Almond, accurately weighed, mix well, and titrate again with tenth-normal silver nitrate until a red tint, which does not disappear on shaking, is reproduced. Conduct this titration as rapidly as possible. Each cc. of tenth-normal silver nitrate corresponds to 0.002702 Gm. of hydrocyanic acid." *U. S.*

Uses.—The unpurified volatile oil of bitter almond, which is the product directed by the Pharmacopœia, acts physiologically like hydrocyanic acid. Death is said to have occurred in a man ten minutes after taking two fluidrachms (7.5 cc.) of the oil. It might be substituted for medicinal hydrocyanic acid, if it always contained a uniform percentage of the acid, as the acid contained in the oil is much less liable to decomposition, remaining for several years unaltered, provided the oil be preserved in well-stoppered bottles. But the proportion is not constant; the U. S. official standard is not less than 2 per cent. and not more than 4 per cent. It has been employed externally, dissolved in water in the proportion of one minim (0.06 cc.) to a fluidounce (30 cc.), in *prurigo senilis* and other cases of troublesome *itching*. To facilitate the solution in water, the oil may be previously dissolved in spirit. Oil of bitter almond is sometimes used to conceal the taste of cod liver oil and of castor oil.

Dose, one-fourth to one minim (0.015–0.06 cc.).

Off. Prep.—Spiritus Amygdalæ Amaræ, *N. F.;* Elixir Amygdalæ Compositum, *N. F.;* Elixir Anisi (from Spirit), *N. F.;* Elixir Aromaticum Rubrum, *N. F.*

OLEUM AMYGDALÆ EXPRESSUM. U. S. (Br.)

EXPRESSED OIL OF ALMOND Ol. Amygd. Exp. [Oil of Sweet Almond]

"The fixed oil obtained from the kernels of varieties of *Amygdalus communis* Linné (Fam. *Dosaceæ*)." *U. S.* "Almond Oil is the oil expressed from the Bitter or Sweet Almond." *Br.*

Oleum Amygdalæ, *Br.;* Almond Oil; Oleum Amygdalæ Dulcis, *U. S.* 1860; Sweet Almond Oil; Huile d'Amande douce, *Fr. Cod.;* Huile d'Amandes, *Fr.;* Oleum Amygdalarum, *P. G.*; Mandel öl, *G.;* Olio di mandorle dolci, *It.;* Aceite de almendras dulces, *Sp.*

This oil is obtained equally pure from sweet and from bitter almonds. In its preparation, the almonds, having been deprived of a reddish-brown powder adhering to their surface, by being rubbed together in a piece of coarse linen, are ground in a mill resembling a coffee-mill, or bruised in a stone mortar, and then pressed in canvas sacks between plates of iron slightly heated. The oil, which is at first turbid, is clarified by rest and filtration. Sometimes the almonds are steeped in very hot water, deprived of their cuticle, and dried in a stove, previous to expression. The oil is thus obtained free from color, but in no other respect better, while it is more likely to become rancid on keeping. Bitter almonds treated in this way impart an odor of hydrocyanic acid to the oil. The yield of oil from the sweet almond is from 40 to 55 per cent. and slightly less from the bitter. Though sometimes expressed in this country from imported almonds, the oil is generally brought from Europe.

Description and Physical Properties.—"A clear, pale straw-colored or colorless, oily liquid. It is almost odorless, and has a bland taste. It is slightly soluble in alcohol, but is miscible with ether, chloroform, benzene, and with petroleum benzin.

"Specific gravity: 0.910 to 0.915 at 25° C. The Oil remains clear at −10° C., and does not congeal until cooled to nearly −20° C. (*olive* or *lard oil*). Shake vigorously for five minutes: 2 cc. of the Oil with a mixture of 1 cc. of fuming nitric acid and 1 cc. of distilled water: the mixture is not more than slightly colored. (*Oil of peach kernels and oil of apricot kernels* yield a red color, and *sesame oil and cottonseed oil* yield a brown color.) Heat 10 cc. of the Oil with 15 cc. of an aqueous solution of sodium hydroxide (1 in 6) and 30 cc. of alcohol on a water bath in a flask, having a small funnel inserted in the neck, and occasionally agitate the mixture until it becomes clear. Transfer the solution to a shallow dish, and evaporate the alcohol on a water bath: the residue, when mixed with 100 cc. of distilled water, produces a clear solution (*paraffin oil*). Add an excess of hydrochloric acid to this solution: a layer of oleic acid rises to the surface which, when separated, washed with warm water, clarified by heating on a water bath, and cooled to 15° C. remains clear for thirty minutes (*various foreign oils.*) One volume of the oleic acid obtained in the preceding test, when mixed with an equal volume of alcohol, yields a clear solution, which, at 15° C., does not deposit any fatty acids, or become turbid upon the further addition of 1 volume of alcohol (*difference from olive, peanut, cottonseed, sesame, and other fixed oils*). Saponification value: not less than 191 and not more than 200. Iodine value: not less than 93 and not more than 100. Preserve in well-closed containers." *U. S.*

"Pale yellow. Nearly inodorous; taste bland and nutty. Specific gravity 0.915 to 0.920. *Saponification value* 188 to 196; *iodine value* 93 to 100; *acid value* not more than 6.0; *refractive index* at 40° C. 1.4624 to 1.4640. Remains clear after exposure for three hours to a temperature of −10° C., and does not congeal till the temperature has been reduced to about −18° C. When 1 millilitre of a freshly prepared mixture of equal parts by weight of *sulphuric acid, fuming nitric acid,* and *water,* kept cool while cautiously mixed, is vigorously shaken with 5 millilitres of the Oil for one minute, a whitish mixture with not more than the very slightest tinge of red or brown is produced; after some hours a white solid, sometimes tinged with green, separates, the lower acid layer remaining colorless (absence of peach oil and apricot oil)." *Br.*

Expressed oil of almond consists chiefly of olein with traces of linolein; there is no stearin present. It belongs among the "non-drying" oils.

It is sometimes adulterated with oils from peach or apricot kernels; these are excluded by the test of the U. S.

Uses.—The expressed oil of almonds possesses the emollient properties of the other fixed oils over most of which it has the advantage of comparative tastelessness, and freedom from odor and its lack of tendency to become gummy.

It is widely employed as an emollient for *chapped hands* and other inflamed conditions of the skin. It is also used to aid the emulsification of the volatile oils.

Dose, one fluidrachm to one fluidounce (3.75–30 cc.).

OLEUM ANETHI. Br.

OIL OF DILL

"Oil of Dill is the oil distilled from Dill Fruit." *Br.*

Huile volatile d'Aneth, Essence d'Aneth, *Fr.;* Dill, Dillöl, *G.*

Oil of dill is of a pale yellow color, with the odor of the fruit, and a hot, sweetish, acrid taste. Its sp. gr. varies between 0.895 and 0.915. The fruit yields about 3.5 per cent. of it.

"Colorless or pale yellow, darkening on keeping. Odor that of Dill Fruit; taste at first sweet and aromatic, but subsequently pungent. Specific gravity 0.900 to 0.915; *optical rotation* +70° to +80°; *refractive index* at 25° C. 1.483 to 1.488. Soluble in 3 parts of *alcohol* (90 per cent.)." *Br.* Dill oil contains from 40 to 60 per cent of carvone, considerable d-limonene and smaller amounts of other terpenes; English and Spanish oils contain phellandrene which, it is said, does not occur in oil of German origin.

East Indian dill oil, which is occasionally used as an adulterant or substitute, comes from a different plant (*Peucedanum Sowa* Kurz.). It differs from the genuine in containing less carvone; small amounts of an apiol are also present.

Dose, from one to three minims (0.065–0.2 cc.).

OLEUM ANISI. U. S., Br.

OIL OF ANISE Ol. Anisi [Anise Oil]

"The volatile oil distilled from the dried ripe fruit of *Pimpinella Anisum* Linné (Fam. *Umbelliferæ*) or from the dried ripe fruit of *Illicium verum* Hooker filius (Fam. *Magnoliaceæ*). The botanical source from which the Oil is derived must be stated on the label. If solid material has separated, carefully warm the Oil until completely liquefied, and mix it thoroughly before dispensing." *U. S.* "Oil of Anise is the oil distilled from Anise Fruit; or from the fruit of the star-anise, Illicium verum, *Hook. f.*" *Br.*

Huile volatile d'Anis vert (Badaine), *Fr. Cod.;* Essence d'Anis, *Fr.;* Oleum Anisi, *P. G.;* Anethol, Anisöl, *G.;* Essenza di anice, *It.;* Esencia de anis, *Sp.*

The product of oil from anise is variously stated at from 1.56 to 3.12 per cent. The oil employed in this country is imported. It is colorless or yellowish, with the peculiar odor and taste of the seed. At 10° C. it crystallizes in flat tables, and it does not melt under 16.6° C. Its sp. gr. increases with age, and is variously given at from 0.9768 to 0.9903. It is miscible in all proportions with ether or dehydrated alcohol.

Description and Physical Properties.—"A colorless or pale yellow, strongly refractive liquid, having the characteristic odor and taste of anise.

"The Oil is soluble with not more than a slight cloudiness in 3 volumes of 90 per cent. alcohol, by volume. Specific gravity: 0.978 to 0.988 at 25° C. Optical rotation: varies from +1° to −2° in a 100 mm. tube at 25° C. Refractive index: 1.5440 to 1.5600 at 20° C. A solution of the recently distilled Oil in 90 per cent. alcohol (1 in 3) is neutral to moistened litmus paper, and develops no blue or brownish color upon the addition of 1 drop of ferric chloride T.S. to 5 cc. of the solution (*phenols*). The Oil meets the requirements of the test for *heavy metals in volatile oils.* The congealing point of Oil of Anise does not fall below 15° C. as determined by the method described on page 1536. Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

"Colorless or pale yellow. Odor that of Anise Fruit; taste sweet and aromatic. Specific gravity at 20° C. (compared with *water* at 15.5° C.) 0.975 to 0.990; *optical rotation* −2° to +1°; *refractive index* at 25° C. 1.552 to 1.558. Congeals, when stirred, at about 15.5° C., and does not again liquefy below 17° C. Not less than 80 per cent. distils between 225° and 235° C. Soluble in 3 parts of *alcohol* (90 per cent.)." *Br.*

Oil of anise contains a small quantity of terpenes, but consists mainly (about 85 per cent.) of methyl-p-propenyl-phenol. This is present both in the solid form, known as estragol, and in the liquid form, anethol. Some samples have been reported as showing traces of safrol. The solidification test of the U. S. P. X is based upon the anethol content. Oil of anise, by exposure to air, is oxidized with the formation of anisic aldehyde, acetic aldehyde and anisic acid, and becomes less disposed to congeal.

The so-called *Japanese star anise oil* (from *Illicium religiosum*) which is from the leaves instead of the fruit. This latter oil contains eugenol and safrol as well as much less anethol than the oil from the fruit. (See *Illicium,* Part II.)

In consequence of its high price, Oil of Anise is frequently adulterated with spermaceti, wax, or camphor. The first two may be detected by their insolubility in cold alcohol, the last by its odor. In one instance as much as 35 per cent. of spermaceti was found. Schimmel & Co. have found fennel stearoptene in commercial oil of anise. (*Ph. Rev.,* 1897, 94). Much of the oil of anise of commerce is the *oil of star aniseed* (*Oleum Badiani,* or *Oleum Illicii*). Oil of anise has also been distilled from the sweet cicely, *Osmorrhiza longistylis* (Torr.) DC., of the United States and Canada. (*Ph. Rund.,* July, 1887.) For description and analysis of Russian oil of anise, see *P. J.,* 1896, 164, also

243. Anisic acid is said to be antiseptic, resembling salicylic acid in its action.

Uses.—As a flavoring agent the oil of anise rivals any of the aromatic oils in the extent of its applicability. It is especially enjoyed by young children. Therapeutically it is useful to stimulate peristalsis in *colic* and, according to Kobert, also as an *expectorant.* It has also been recommended as a means of destroying body lice. Parutz (*Schim. Rep.,* 1920) has used a 1 per cent. ointment for *scabies.*

Dose, from three to five minims (0.2–0.3 cc.).

Off. Prep.—Aqua Anisi, *U. S.;* Elixir Aromaticum (from Spirit), *U. S.;* Spiritus Anisi, *U. S., Br.;* Spiritus Aurantii Compositus, *U. S.*

OLEUM ANTHEMIDIS. Br.

OIL OF CHAMOMILE

"Oil of Chamomile is the oil distilled from Chamomile Flowers." *Br.*

Oleum Chamomillæ Romanæ; Essence de Camomille romaine, *Fr.;* Römisch-Kamillenöl, *G.*

The yield of this oil by chamomile flowers ranges from 0.8 to 1.5 per cent. It has the peculiar odor of chamomile, with a pungent somewhat aromatic taste.

It is "blue when freshly distilled, but gradually becoming greenish or brownish-yellow under the influence of air and light. Odor that of Chamomile Flowers; taste aromatic, characteristic. Specific gravity 0.905 to 0.915. *Optical rotation* –1° to +3°; *refractive index* at 25° C. about 1.445. Soluble in less than 1 part of *alcohol* (90 per cent.)." *Br.*

For account of the chemistry of this oil see under *Anthemidis Flores.* It has sometimes been employed in spasm of the stomach, and as an adjunct to purgative medicines. Its chief use, however, appears to be as an ingredient of the extract of chamomile of the British Pharmacopœia, to which it is added in order to supply the place of the oil driven off by the heat used in its preparation. This oil must not be confounded with that of *Matricaria Chamomilla* L. employed on the continent of Europe under the name of oil of chamomile. (See *Matricaria.*)

Dose, one to three minims (0.06–0.2 cc.).

OLEUM ARACHIS. Br.

ARACHIS OIL

Arachis Oil is the oil expressed from the seeds of Arachis hypogæa, *Linn.*

Earth-nut Oil, Ground-nut Oil, Pea-nut Oil.

For description of the pea-nut plant (*Arachis hypogæa*), see *Ground-nuts,* Part II. The oil consists of the glycerides of oleic acid and in smaller amount of linoleic, hypogeic, arachidic and lignoceric acids. It should be obtained by expression without heat. It is usually of a pale yellowish or green color with a faint odor, and a more distinct taste of the nuts, although on clarification a nearly colorless and tasteless oil may be obtained. Upon exposure to the air the oil slowly thickens and becomes rancid. It is soluble in all proportions in ether, chloroform, and petroleum benzin, but insoluble in alcohol.

"Pale yellow or greenish-yellow. Faint, nutlike odor; taste bland, nutty. Specific gravity 0.916 to 0.921; *saponification value* 190 to 196; *iodine value* 83 to 101; *acid value* not more than 6; *refractive index* at 40° C. 1.4628 to 1.4645. When 1 millilitre of the Oil and 15 millilitres of *N/1 alcoholic solution of potassium hydroxide* are boiled for twenty minutes in a flask provided with a reflux condenser, set aside for twenty-four hours at a temperature not exceeding 15.5° C., and afterwards heated on a water-bath for three minutes, the solution deposits crystals on standing. When a mixture of 2 millilitres of the Oil and 1 millilitre of *hydrochloric acid* containing 1 per cent. of *refined sugar* is shaken for half a minute, and allowed to stand for five minutes, the acid layer does not become pink (absence of sesame oil). When 2 millilitres of the Oil are mixed with 1 millilitre of *amylic alcohol* and 1 millilitre of a solution (1 in 100) of *precipitated sulphur* in *carbon disulphide,* and the mixture heated in a test-tube immersed in boiling *water,* no red color is developed within fifteen minutes (absence of cotton seed oil)." *Br.*

At 3.3° C. it thickens, solidifies at about –5° C., and at 326.6° C. is decomposed, giving out spontaneously inflammable vapors. Winter made experiments to ascertain how far it might be employed with advantage in pharmacy, and found that it answered well in the preparation of cerates and ointments, but would not serve as a substitute for olive oil in the preparation of lead plaster. (See *Proc. A. Ph. A.,* 1897, 179.) Its use is permitted, by the British Pharmacopœia, in India, and in the Eastern, African, and Australasian Divisions of the Empire, for making the official Liniments, Ointments, Plasters, and Soaps for which Olive Oil is directed to be used. It is a non-drying oil, and therefore will not answer for painting; but it has been enormously used for adulteration (particularly of French olive oils) and for various purposes in the arts, as for lubricating machinery, and in the manufacture of woollen cloths; in lamps it burns with a bright light. It saponifies slowly, but yields an excellent firm, white, and odorless soap.

OLEUM AURANTII. U. S.

OIL OF ORANGE Ol. Aurant. [Orange Oil, Oil of Sweet Orange]

"The volatile oil obtained by expression from the fresh peel of the ripe fruit of *Citrus Aurantium* var. *sinensis* Linné (Fam. *Rutaceæ*). Oil of Orange which has a terebinthinate odor must not be dispensed." *U. S.*

Oleum Aurantii Corticis, *U. S. VIII;* Oleum Aurantiorum; Essential Oil of Orange Peel, Essence of Orange; Huile volatile d'Orange, *Fr. Cod.;* Essence de Portugal, *Fr.;* Apfelsiunencharenöl, Pomeranzenschalenöl, *G.;* Essenza di arancio amara, Essenza della corteccia, *It.*

This oil is used only for flavoring purposes, and has been introduced principally because of its employment in elixirs and in *Spiritus Aurantii Compositus.*

The oil of orange is obtained either by expression or distillation. One method which has been employed in Sicily from very early times is to remove the pulp of the fruit and press the rind by hand against a sponge which absorbs the oil as it is expressed. Sometimes the oil is expressed by machinery. The "écuelle" process (see under *Oleum Limonis*) is largely employed in France and also in Jamaica (*D. C.*, 1918, lxii, p. 196); the oranges are rolled in vessels thickly studded with sharp points and the oil collected as it oozes out of the wounds.

Oil of orange peel consists, as has been shown by Wallach, of d-limonene to the extent of at least 90 per cent.; of the remainder, about 5 per cent. are the odorous constituents, among which are citral, traces of citronellal, and the methyl ester of anthranilic acid. (See under *Indigo,* Part II.) The inner thick part of the rind contains also a bitter principle, called hesperidin (see under *Limonis Cortex*).

Description and Physical Properties.—"A yellow liquid, having the characteristic odor and taste of the outer part of sweet orange peel.

"The Oil does not form a clear solution with 2 volumes of 90 per cent. alcohol, by volume, (*washed citrus oils*). It is soluble in all proportions in dehydrated alcohol and in carbon disulphide, and in an equal volume of glacial acetic acid. Specific gravity: 0.842 to 0.846 at 25° C. Optical rotation: not less than + 94° and not more than + 99° in a 100 mm. tube at 25° C. Refractive index: 1.4723 to 1.4737 at 20° C. A solution of recently expressed Oil of Orange in dehydrated alcohol is neutral to moistened litmus paper. The Oil meets the requirements of the test for *heavy metals in volatile oils.* A 25 Gm. portion of Oil of Orange evaporated to dryness at a temperature not exceeding 100° C. yields not less than 2 per cent. of residue (*washed citrus oils*). Place 50 cc. of Oil of Orange in a 250 cc. three-bulb Ladenburg flask of approximately the following dimensions: The lower or main bulb, 6 cm. in diameter, with the smaller condensing bulbs 3.5 cm., 3.0 cm. and 2.5 cm., respectively, in diameter; the distance from the bottom of the flask to the side arm, 20 cm. Distil the Oil at the rate of 1 drop per second until the distillate measures 5 cc.: the angle of rotation of the distillate is equal to that of the original Oil, or does not differ more than 2 degrees from it, and the refractive index of the distillate is not less than 0.0008 and not more than 0.0015 lower than that of the original Oil at 20° C.

"Preserve in small, completely filled, well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

A waxy non-volatile substance is present in oil of orange, which interferes with the transparency of solution made with 90 per cent. alcohol. This oil is one of the most difficult to preserve. A method for its preservation, which we have used for years, is to shake the oil briskly with one-eighth of its volume of distilled water, and allow it to separate, then remove the essential oil, filter rapidly if necessary, and mix the filtered oil with 95 per cent. alcohol in the proportion of one volume of the oil to seven volumes of alcohol.

It may be preserved indefinitely by adding 10 per cent. of its volume of olive oil.

The oil of orange is used chiefly as a flavoring agent but Zickgraf (*M. M. W.*, 1910, lvii, p. 1070) speaks very highly of its effect in *chronic bronchitis* for the same class of cases in which oil of turpentine is used. It has the advantages over the latter of being much more pleasant to take and non-irritant to the kidneys.

Dose, three to five minims (0.2–0.3 cc.).

Off. Prep.—Elixir Aromaticum (from Compound Spirit), *U. S.;* Spiritus Aurantii Compositus, *U. S.;* Elixir Cardamomi Compositum (from Compound Spirit), *U. S.;* Elixir Pepsini Compositum, *N. F.;* Spiritus Cardamomi Compositus, *N. F.;* Spiritus Myrciæ Compositus, *N. F.;* Spiritus Vanillini Compositus, *N. F.*

OLEUM AURANTII AMARÆ. N. F.

OIL OF BITTER ORANGE Ol. Aurant. Amar.

"A volatile oil obtained by expression from the fresh peel of the bitter orange, *Citrus Aurantium* Linné (Fam. *Rutaceæ*)." *N. F.*

Oil of Orange; Oil of Bigarade; Essence de Bigarade, *Fr.;* Oleum Aurantii Corticis, *G.*

Description and Physical Properties.—"Oil of Bitter Orange is a pale yellow liquid, having the characteristic, aromatic odor of the Seville orange, and an aromatic somewhat bitter taste. Soluble in 4 volumes of alcohol, the solution being neutral to litmus paper. Also soluble in all proportions in dehydrated alcohol and in an equal volume of glacial acetic acid.

"Specific gravity: 0.842 to 0.848 at 25° C. It is dextrorotatory, the angle of rotation varying from +88 to +98°, in a 100 mm. tube, at 25° C. Introduce 50 cc. of Oil of Bitter Orange into a 200 cc. three-bulb, fractionating flask of approximately the following dimensions; the lower or main bulb 6 cm. with smaller condensing bulbs 3.5 cm., 3.0 cm. and 2.5 cm. in diameter, respectively; with the distance from the bottom to the side arm 20 cm. Distil the Oil at the rate of 2 cc. per minute until a distillate measuring 6 cc. has been collected. The angle of rotation of this distillate is equal to, or only slightly lower than, that of the original Oil.

"Preserve it in small, well-stoppered, amber-colored bottles, in a cool place, protected from light. Oil of Bitter Orange having a terebinthinate odor is not to be dispensed." *N. F.*

Dose, from three to five minims (0.2–0.3 cc.).

Off. Prep.—Elixir Aurantii Amari, *N. F.*

OLEUM AURANTII FLORUM. N. F.

OIL OF ORANGE FLOWERS Ol. Aurant. Flor.
[Oil of Neroli]

"A volatile oil distilled from the fresh flowers of the bitter orange, *Citrus Aurantium* Linné (*Citrus vulgaris* Risso, *Citrus Bigaradia* Risso) (Fam. *Rutaceæ*)." *N. F.*

Oleum Neroli; Oil of Neroli; Oleum Naphae; Pomerantzenblüthenöl, *G.;* Esencia de Azahar, Esencia de Flor de Naranjo, *Sp.*

Various sweet-smelling oils have been prepared from different species of oranges. From the flowers of the sweet orange is obtained a very fragrant oil known as *néroli petale.* From the flowers of the bitter orange a similar although somewhat inferior perfume which is called *néroli bigarade;* this is the oil official in the N. F. The *oil of petit grain* (*huile de petit grain citronnier, essence de petit grain*) was originally obtained from the unripe fruits but is now distilled from the twigs and leaves of the lemon tree. It is often used for adulterating the true orange flower oil. (*C. D.*, 1897, p. 53.)

Description and Physical Properties.—"Oil of Orange Flowers is a pale yellow, slightly fluorescent, neutral liquid, having a distinctive fragrant odor, similar to that of orange blossoms, and an aromatic, at first sweet then somewhat bitter taste.

"It is soluble in an equal volume of alcohol, the solution having a violet fluorescence and a neutral reaction to litmus paper. Also soluble in two volumes of 80 per cent. alcohol, the solution becoming cloudy on the further addition of alcohol of the same percentage. Specific gravity: 0.868 to 0.880 at 25° C. It is dextrorotatory, the angle of rotation varying from +1° 30′ to +5° in a 100 mm. tube, at 25° C.

"Preserve it in small, amber-colored, well-stoppered bottles in a cool place, protected from light." *N. F.*

Neroli oil is one of the most complex of all of the volatile oils in its constitution. It contains the following constituents: l-a-pinene, l-camphene, limonene, dipentene, decyl aldehyde, phenyl-ethyl alcohol, nerol, linalool, d-terpineol, nerolidol, geraniol, acetic esters of the various alcohols mentioned, indol, traces of benzoic, palmitic and phenylacetic acids in the form of esters, linalyl acetate, and several paraffin hydrocarbons. A fluorescent substance, methyl o-amido benzoate, is also present. Noel distinguishes the different volatile oils of the orange tribe by shaking five drops of the oil with one cc. of pure concentrated hydrochloric acid. After one minute seven or eight cc. of 90 per cent. alcohol are added, whereby the color is changed, and increased or decreased according to the extent of the adulteration. It is obvious that to use effectually such a test requires special education. (See *Proc. A. Ph. A.*, 1887.)

Under the name of *nerolin* an artificial product has been placed upon the market in the form of a white crystalline powder, soluble in alcohol and fixed oils and almost insoluble in water. It is used by soap makers as a substitute for oil of neroli, and is said to be ten times as strong. This compound is said to be the *ethyl ether of β-naphthol.* (*B. Chem. G.*, 1893, 2706.) It is also used in the manufacture of eau-de-Cologne with advantage instead of neroli oil. (*Schim. Rep.*, April, 1893.) Oil of neroli of excellent quality is now produced artificially; Schimmel & Co. state that it contains pinene, camphene, dipentene, terpineol, phenyl-acetic acid, benzoic acid, decylic aldehyde, and linalool.

Oil of orange flowers is used only as a perfuming agent.

Off. Prep.—Spiritus Odoratus, *N. F.*

OLEUM BERGAMOTTÆ. N. F.

OIL OF BERGAMOT Ol. Bergam.

"A volatile oil obtained by expression from the rind of the fresh fruit of *Citrus Aurantium* Linné var. *Bergamia* (Risso et Poiteau), Wight et Arnott (Fam. *Rutaceæ*), and containing not less than 36 per cent. of ester, calculated as linalyl acetate." *N. F.*

Oleum Bergami; Essentia Bergamothæ; Bergamottol, *G.;* Essence de Bergamotte, *Fr.*; Esentia de Bergamota, *Sp.*

The bergamot tree has oblong-ovate, dentate, acute, or obtuse leaves, somewhat paler on the under than on the upper surface, and with winged petioles. The flowers are white, and usually small; the fruit is a pyriform or globular, thin skinned hesperidium, about three inches in diameter. The pulp of the fruit is sour, somewhat aromatic, and not disagreeable. The rind is shining, and of a pale-yellow color, and abounds in volatile oil. This may be obtained by expression or distillation. In the former case it preserves the agreeable flavor of the rind, but is somewhat turbid; in the latter it is limpid but less sweet. The mode of procuring it by expression is exactly the same as that used for oil of lemon. (See *Oleum Limonis.*) The bergamot tree is extensively cultivated in Calabria for its essential oil which is used in the preparation of Eau de Cologne and various perfumes. It is brought from Italy, the south of France, and Portugal.

Description and Physical Properties.—"Oil of Bergamot is a green or greenish-yellow liquid, neutral or only faintly acid, having a characteristic fragrant odor and an aromatic bitter taste. Two volumes of the Oil, when mixed with 1 volume of alcohol, give a clear solution and this does not become turbid on the further addition of alcohol. It is soluble in 2 volumes of 80 per cent. alcohol with not more than a slight cloudiness, and no separation of oil globules. Also soluble in all proportions in glacial acetic acid.

"Specific gravity: 0.875 to 0.880 at 25° C. It is dextrorotatory, the angle of rotation varying from +8° to +24°, in a 100 mm. tube at 25° C. Evaporate in a tared dish on a water bath about 2 Gm. of the Oil, accurately weighed, until the odor has completely disappeared; a soft green residue remains, corresponding to not more than 6 per cent. of the Oil (*fixed oils*). To 2 Gm. of Oil of Bergamot add 10 cc. of half normal alcoholic potassium hydroxide, free from chloride, evaporate to dryness and incinerate. Extract the ash with distilled water and acidify with diluted nitric acid; no cloudiness is produced on the addition of silver nitrate T.S. (*chlorinated compounds*).

"**Assay.**—To 2 Gm. of the Oil add 20 cc. of half-normal alcoholic potassium hydroxide, and heat the mixture in a flask on a water bath, under a reflux condenser, for a half hour. Cool the mixture, add 100 cc. of distilled water and titrate with half-normal sulphuric acid, using phenolphthalein T.S. as indicator. Not more than 12.6 cc. of half-normal sulphuric acid is required, corresponding to not less than 36 per cent. of ester, calculated as linalyl acetate, in the Oil. Each cc. of half-normal potassium hydroxide consumed corresponds to 0.09808 Gm. of ester, calculated as linalyl acetate.

"Preserve it in small, amber-colored, well-stoppered bottles in a cool place, protected from light." *N. F.*

The oil of bergamot contains limonene, dipentene, linalool, a solid greasy compound called *bergaptene*, or *bergamot camphor*, and linalool acetate, which latter makes up about 40 per cent. of the expressed oil, but is decomposed in large part by the process of steam distillation. Bergaptene has been very fully studied by Pomeranz. (*M. Chem.*, 1891, 379.) It melts at 188° C., and has the composition $C_{12}H_8O_4$, being the lactone or inner anhydride of *bergaptenic acid*, $C_{12}H_{10}O_5$. By fusion with potassium hydroxide, bergaptene yields phloroglucin. (See *Schim. Rep.*, April, 1893, and 1895, 24; also *Proc. A. Ph. A.*, 1897, 630.) The oil is distinguished from lemon and orange oils by readily dissolving in solution of potassium hydroxide and forming with it a clear solution.

Though possessed of the stimulant properties of the volatile oils in general, it is employed chiefly as a perfume. According to Galewsky (*Ph. Ztg.*, 1915, lx, p. 55), the oil of bergamot is an extraordinarily active insecticide and useful to protect the body against lice and other vermin.

It is often adulterated. (See *C. D.*, 1908, 383; also 1910, 52.)

Off. Prep.—Spiritus Odoratus, *N. F.*

OLEUM BETULÆ EMPYREUMATICUM RECTIFICATUM. N. F.

RECTIFIED OIL OF BIRCH TAR Ol. Bet. Empyr. Rect.

"The pyroligneous oil obtained by the dry distillation of the bark and wood of *Betula alba* Linné (Fam. *Betulaceæ*), rectified by steam distillation." *N. F.*

Rectified Empyroligneous Oil of Birch; Oleum Rusci Rectificatum; Oleum Muscoviticum; Pix Betulina; Oleum Fagi; Oleum Betulinum; Lithanei Balsamum; Dagget; Birkentheer, Birkenöl, *G.*

From the bark of the European white birch there is obtained, especially in Russia, by a process of destructive distillation a tar-like product. From this by distillation is obtained the liquid recognized by the N. F. It is, however, not certain whether the rectification has removed some of the valuable constituents. (For description of the white birch, see *Betula*, Part II).

Description and Physical Properties.—"Rectified Oil of Birch Tar is a limpid, dark brown liquid having a penetrating, empyreumatic odor resembling that of Russia leather. It yields clear solutions with 3 volumes of dehydrated alcohol, and with ether, chloroform, glacial acetic acid, amyl alcohol, oil of turpentine, benzene or carbon disulphide. When mixed with 3 volumes of alcohol or purified petroleum benzin, the solution is not more than slightly turbid, but a decided turbidity is produced when mixed with the same volume of methyl alcohol.

"Specific gravity: 0.886 to 0.950 at 25° C. Warm 2 cc. of the Oil with 10 cc. of distilled water, agitate and allow the mixture to cool; separate and filter the aqueous liquid. The filtrate is colorless, has a strong, empyreumatic odor and an acid reaction. Add two drops of potassium dichromate T.S. to 4 cc. of the aqueous filtrate; it produces a bright yellow solution which soon becomes darker and turbid. Add one drop of dilute ferric chloride solution (1 in 100) to 4 cc. of the filtrate; it produces a green coloration which changes to brown and becomes turbid (distinction from *oil of cade*)." *N. F.*

It contains guaiacol, creosol, cresol, xylenol and traces of phenol. Dutch and German *oil of birch* are quite different from the Russian oil. (See *P. J.*, xv, 769.)

Uses.—This oil has been found useful as a local application in *chronic eczema* and other *skin diseases* in strengths varying between 1 and 20 per cent. Its medicinal properties closely resemble those of oil of cade. (See *Oleum Cadini.*)

Off. Prep.—Unguentum Resorcinolis Compositum. *N. F.*

OLEUM CADINUM. U. S., Br.

OIL OF CADE Ol. Cadin. [Cade Oil, Oleum Juniperi Empyreumaticum]

"The empyreumatic volatile oil obtained from the wood of *Juniperus Oxycedrus* Linné (Fam. *Pinaceæ*)." *U. S.* "Oil of Cade is an empyreumatic oily liquid obtained by the destructiye distillation of the woody portions of Juniperus Oxycedrus, *Linn.*" *Br.*

Oil of Juniper Tar; Juniper Tar Oil; Huile de Cade, *Fr.*; Kadeöl, Kadiöl, *G.*

The *Juniperus Oxycedrus* Linné, *prickly cedar*, or *large brown-fruited juniper*, is a common tree in the waste places and stony hill-sides of the Mediterranean districts of northern Africa, Spain, Portugal, and France, reaching up in its distribution as high as 3000 feet in the Apennines. It commonly attains a height of from ten to twelve feet, with long spreading branches and slender drooping branchlets, covered with light-green scattered and spreading leaves of medium size, lanceolate or awl-shaped, sharply pointed, having two white lines on their upper surface. The fruits are numerous, large (one-fourth to one-third of an inch in diameter), globular, shining, reddish or chestnut-brown, and marked on the apex with three white scars indicating the separation of the carpels.

From the heart wood of this tree the oil of cade is prepared by destructive distillation. Pieces of the wood are placed on a concave slab from the center of which a pipe leads downward and over them is inverted an iron pot and heated by means of small pieces of the wood. According to Huerre (*J. P. C.*, 1921, xxiii, p. 441) in this process much of the volatile oil of the wood is distilled over—some after partial decomposition—which acts as a solvent for the heavier tar-like bodies.

Oil of cade is a brown liquid, much more mobile and less thick than tar, having a tar-like but distinct odor, and a smoky, acrid, bitterish, disagreeable taste. In mass it is dark and opaque, but in very thin layers clear.

Description and Physical Properties.—"A dark brown, clear, thick liquid, having a tarry odor, and a warm, faintly aromatic, bitter taste. The Oil is very slightly soluble in water, but imparts to it an acid reaction shown by moistened blue litmus paper. It is only partially soluble in alcohol and in petroleum benzin, but completely soluble in 3 volumes of ether and soluble in all proportions in amyl alcohol, chloroform, glacial acetic acid, and in oil of turpentine.

"Specific gravity: 0.980 to 1.055 at 25° C. Shake 1 part of Oil of Cade with 20 parts of warm distilled water, and filter: separate portions of 5 cc. each of the aqueous filtrate give a red coloration with 3 drops of ferric chloride solution (1 in 1000), blacken silver ammonium nitrate T.S. in the cold, and give a red precipitate with alkaline cupric tartrate T.S. on heating. Agitate 1 cc. of Oil of Cade with 15 cc. of purified petroleum benzin, filter the solution, add an equal volume of copper acetate solution (1 in 100), shake the mixture, and allow it to separate. Decant the benzin layer into a test tube, and add to it an equal volume of ether: no intensely green coloration is produced, nor does the liquid become more than light yellow to brown (*rosin* or *rosin oils*)." *U. S.*

"A dark reddish-brown or nearly black, oily liquid. Empyreumatic odor; taste aromatic, bitter and acrid. Specific gravity about 0.990. Soluble in *ether*, and in *chloroform;* partially soluble in cold, almost wholly soluble in hot *alcohol* (90 per cent.); very slightly soluble in *water*, the filtered aqueous solution being almost colorless and acid to *litmus*. Yields no reaction for pine tar when tested as follows: Shake 1 millilitre of the Oil vigorously with 15 millilitres of *petroleum spirit*, and filter; to 10 millilitres of the filtrate add 10 millilitres of *solution of copper acetate*, shake vigorously, and set aside until separation into two layers is complete; 5 millilitres of the upper layer, when mixed with 10 millilitres of *ether*, become pale brownish-yellow, but not green (absence of pine tar)." *Br.*

This oil contains phenols and a sesquiterpene termed *cadinene*, $C_{15}H_{24}$, the latter boiling at from 274° to 275° C., and having a sp. gr. of 0.918 at 20° C., also acetic acid, hydrocarbons boiling from 210° to 400° C., resin phenolic bodies, derivatives of pyrocatechin, such as guaiacol and its ethyl and propyl derivatives, and creosol.

Yaucher recommends acetone for disguising the odor of oil of cade, and proposes an *oil of cade collodion* in which acetone is used to dissolve the pyroxylin instead of the usual solvents. (*C. D.*, 1897, 16.)

Uses.—Oil of cade has been used locally, by the peasantry, in the treatment of the cutaneous diseases of domestic animals almost from time immemorial. More recently it has been largely employed in the treatment of *chronic eczema, psoriasis,* and other skin diseases of man, and has also been found to be an efficient parasiticide in *psora* and *favus*. It is applied, sometimes of full strength, sometimes diluted with a bland oil, well rubbed into the affected parts with the fingers, or with a cloth, and is also made into ointments, and especially into soaps. A glycerite is also prepared. It is very rarely, if ever, used internally, but probably resembles oil of tar in its physiological action.

Dose, one to three minims (0.06–0.2 cc.).

Off. Prep.—Linimentum Saponis Mollis Compositum, *N. F.;* Petroxolinum Cadinum, *N. F.;* Petroxolinum Sulphuratum Compositum, *N. F.;* Unguentum Sulphuris Compositum, *N. F.*

OLEUM CAJUPUTI. U. S., Br.

OIL OF CAJUPUT Ol. Cajup. [Cajuput Oil Oil of Cajeput]

"The volatile oil distilled from the fresh leaves and twigs of several varieties of *Melaleuca Leucadendron* Linné, especially the var. *Cajeputi* (Roxburgh) Niedenzu and the var. *minor* (Smith) Duthie (Fam. *Myrtaceæ*), rectified by steam distillation." *U. S.* "Oil of Cajuput is the oil distilled from the leaves of Melaleuca Leucadendron, *Linn.*, and other species of Melaleuca." *Br.*

Oleum Cajeputi; Essence de Cajeput, Huile volatile de Cajeput, *Fr.;* Cajeputöl, *G.;* Essenza di Cajeput, *It.;* Esencia de Cayeput, *Sp.;* Kayuputieh, *Mal.*

It was long supposed that the *oil of cajuput* was derived only from *Melaleuca Leucadendron*, but it is now well established that it is derived chiefly from one or more varieties of this species. They are trees indigenous to upper India, the Islands of the Indian Ocean, northern Australia, Queensland and New South Wales. (See *The Volatile Oils*, Gildemeister and Hoffmann.)

Stickel of Jena, succeeded in procuring from the leaves of *M. hypericifolia* Sm., cultivated in the botanical garden of that place, a specimen of oil not distinguishable from the cajuput oil of commerce, except by a pale-green color. (*Ann. Pharm.*, xix, 224.)

Melaleuca Leucadendron Linné (*M. Cajuputi* Roxb.)—commonly known as *cajuput tree, punk tree* and *swamp tea tree*—is a large tree with crooked trunk, thick, pale-buff, spongy bark and scattered branches bearing pendulous twigs. The leaves are alternate, elliptic or oblong, when young sericeous, when full-grown smooth, deep green, 3 to 7 nerved, slightly falcate, entire, from three to five inches long, from one-half to three-quarters of an inch broad, and when bruised exhale a strong aromatic odor. The flowers are small, white, varying to pink and purple in Australia, inodorous, sessile, and disposed in terminal and axillary downy spikes, with solitary, lanceolate, three-flowered bracts. The filaments are three or four times longer than the petals, and both are inserted in the rim of the calyx. The oil is obtained from the leaves by distillation. It is prepared chiefly in Amboyna and Bouro, and is exported from the East Indies in glass bottles. The small proportion yielded by the leaves and the extensive use made of it in India render it somewhat costly.

Description and Physical Properties.—"A colorless or yellowish liquid, having a peculiar, agreeable distinctly camphoraceous odor, and an aromatic, slightly bitter taste.

"The Oil is soluble in 1 volume of 80 per cent. alcohol. Specific gravity: 0.912 to 0.925 at 25° C. Optical rotation: does not exceed –4° in a 100 mm. tube at 25° C. Refractive index: 1.4660 to 1.4710 at 20° C. Oil of Cajuput meets the requirements of the test for *heavy metals in volatile oils*.

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

"Green or bluish-green. Agreeable, camphoraceous odor; taste aromatic, bitter and camphoraceous. Specific gravity 0.919 to 0.930; *optical rotation* not more than –4°; *refractive index* at 25° C. 1.460 to 1.467. When 10 millilitres of the Oil are mixed with 4 to 5 millilitres of *syrupy phosphoric acid* in a vessel surrounded by a freezing mixture, and then pressed strongly in a piece of fine calico between folds of blotting-paper, the pressed cake, decomposed by warm *water* in a graduated vessel, yields an oily layer, which, on cooling to 15.5° C., measures not less than 4.5 millilitres (presence of not less than 45 per cent. of cineol)." *Br.*

The U. S. requires the oil to be colorless or yellow, but according to the Br. it has a greenish tint. When it is distilled, a light, colorless liquid first comes over, and afterwards a green and denser one. The green color is due to a salt of copper derived from the vessels in which the distillation is performed, and Guibourt obtained two grains and a half of copper oxide from a pound of the commercial oil. The oil may be obtained colorless by redistillation.

Constituents.—This oil contains as its chief ingredient about from 40 to 65 per cent. of *cajuputol,* which is identical with cineol (see *Eucalyptol*). There is present also a small amount of the solid terpineol, both in the free state and as an acetic ester, also l-pinene and traces of butyric, valeric and benzoic aldehydes (*Schim. Rep.*, April, 1897).

Oil of cajuput is said to be often adulterated with oils derived from other than the official species of *Melaleuca.* Oil of rosemary, and oil of turpentine, impregnated with camphor and colored with the resin of milfoil, are also said to be employed as adulterants. The best test, according to Zeller, is iodine; this, after a moderately energetic reaction, with little increase of temperature and but a slight development of orange vapors, occasions immediate inspissation into a loose coagulum, which soon becomes a dry, greenish-brown, brittle mass.

Uses.—This oil is highly stimulant, producing when swallowed, a sense of heat, with an increased fulness and frequency of pulse, and exciting in some instances profuse perspiration. It is much esteemed by the Malays and other people of the East, who consider it a panacea. Formerly the oil of cajuput was used internally in *chronic rheumatism, low fevers,* and various other complaints, but is rarely employed at present for its alterative effects. It is useful internally as a stimulating expectorant in *chronic laryngitis* and *bronchitis,* and as an anthelmintic especially against the *round worm.* Its most frequent uses, however, are externally in the treatment of various skin diseases. For this latter group of affections it is used for its antiparasitic effect in such diseases as *scabies, tinea versicolor,* etc., and for its stimulating action in *acne rosaceæ, psoriasis,* and other chronic conditions. It is also used externally as a counter-irritant in *chronic rheumatism* and other painful conditions. Like many other essential oils it *relieves toothache* if introduced into the hollow carious tooth.

Dose, from three to ten minims (0.2–0.6 cc.).

Off. Prep.—Linimentum Crotonis, *Br.;* Spiritus Cajuputi, *Br.;* Linimentum Tiglii, *N. F.*

OLEUM CARDAMOMI. N. F.

OIL OF CARDAMOM Ol. Cardam.

"A volatile oil distilled from the seeds of *Elettaria Cardamomum,* (Linné) Maton (Fam. *Zingiberaceæ*)." *N. F.*

This oil has been introduced into the National Formulary as an ingredient of compound spirit of cardamom, which is an ingredient in compound elixir of cardamom. It is also used as a flavor in other elixirs. It is to be regretted that cardamom seeds were not used instead of this oil which is largely adulterated. In fact oil of cardamom has been found in the market made from oils which contain no oil of cardamom whatsoever. The high price of cardamom seeds and the small percentage of volatile oil found in them offers an extraordinary inducement to adulterators. Care must therefore be used to employ only the oil which complies strictly with the requirements of the National Formulary. It is described as follows:

Description and Physical Properties.—"Oil of Cardamom is a colorless or very pale yellow liquid having the characteristic aromatic, penetrating and somewhat camphoraceous odor of cardamom, and a persistent, pungent, and strongly aromatic taste. It is very soluble in alcohol and readily soluble in four volumes of 70 per cent. alcohol, forming a clear solution.

"Specific gravity: 0.924 to 0.947 at 25° C. It is dextrorotatory, the angle of rotation varying from +22° to +44°, in a 100 mm. tube at 25° C.

"Preserve it in small, well-stoppered amber-colored bottles, in a cool place, protected from light." *N. F.*

For further description of this oil see *Cardamomi Semen.*

Oil of cardamom is not used medicinally but solely for pharmaceutical purposes.

Off. Prep.—Spiritus Cardamomi Compositus, *N. F.*

OLEUM CARI. U. S. (Br.)

OIL OF CARAWAY Ol. Cari. [Caraway Oil]

"The volatile oil distilled from the dried ripe fruit of *Carum Carvi* Linné (Fam. *Umbelliferæ*). Oil of Caraway yields not less than 50 per cent. by volume of carvone [$C_{10}H_{14}O$]." *U. S.* "Oil of Caraway is the oil distilled from Caraway Fruit, and rectified." *Br.*

Oleum Carui, *Br.;* Huile volatile de Carvi, *Fr. Cod.;* Essence de Carvi, *Fr.;* Oleum Carvi, *P. G.*; Kümmelöl, Carvon, *G.*

This oil is prepared to a considerable extent by our distillers. The fresh fruit as cultivated in Holland yields nearly 6 per cent. of oil, while the German fruit yields about 4 per cent.

Description and Physical Properties.—"A colorless or pale yellow liquid, having the characteristic odor and taste of caraway.

"The Oil is soluble in 8 volumes of 80 per cent. alcohol, by volume. Specific gravity: 0.900 to 0.910 at 25° C. Optical rotation: varies from + 70° to + 80° in a 100 mm. tube at 25° C. Refractive index: 1.4840 to 1.4880 at 20° C. Oil of Caraway meets the requirements of the test for *heavy metals in volatile oils.*

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

"Colorless or pale yellow. Odor and taste those of Caraway Fruit. Specific gravity 0.910 to 0.920; *optical rotation* + 75° to + 82°; *refractive index* at 25° C. 1.485 to 1.497. Soluble in 1 part of *alcohol* (90 per cent.), and in 10 parts of a mixture of equal volumes of *alcohol* (90 per cent.) and *alcohol* (70 per cent.). When fractionally distilled from a distillation flask at the rate of one drop per second, not less than 50 per cent. distils at a temperature above 200° C." *Br.*

Assay.—"Place 10 cc. of Oil of Caraway, measured from a pipette, in a 100 cc. cassia flask and add 50 cc. of a saturated solution of sodium sulphite, which has been carefully rendered neutral to 2 drops of phenolphthalein T.S. by means of a 5 per cent. sodium bisulphite solution. Heat the mixture in a bath containing boiling water, and shake the flask repeatedly, neutralizing the mixture from time to time by the addition of a few drops of the 5 per cent. sodium bisulphite solution. When no coloration appears upon the addition of a few more drops of phenolphthalein T.S. and heating for fifteen minutes, cool to room temperature, and, when the liquids have separated completely, add sufficient sodium sulphite solution to raise the lower limit of the oily layer within the graduated portion of the neck. Note the volume of the residual liquid. This measures not more than 5 cc., indicating the presence of not less than 50 per cent. by volume of carvone." *U. S.*

For additional tests, see *Schim. Rep.*, 1893, 10; also *Bull. Pharm.*, 1894, 257. Kremers and Schreiner (*Ph. Rev.*, xiv, 67) recommend a method of determining the value of oil of caraway based on the conversion of carvone into its oxime, and the separation of the carvoxime from the terpenes by steam distillation; it is as follows: "To a solution of 10 Gm. of oil, dissolved in 25 cc. of alcohol, 5 Gm. of hydroxylamine hydrochloride and 6.5 Gm. of sodium bicarbonate are added. This mixture is boiled on a water bath for half an hour in a flask connected with a reflux condenser, 25 cc. of water are then added, and the alcohol is distilled off on the water bath. Steam is then passed through the liquid until traces of carvoxime come over. The last portions of the distillate are collected separately in test tubes, and when traces of crystals of carvoxime appear on the surface, the operation is interrupted. The tube of the condenser is washed with a little hot water, and this, as well as the last collected distillate, containing some carvoxime, is returned to the flask. The contents of the flask are allowed to cool, and after the carvoxime has completely solidified, it is removed from the sides of the flask by means of a loop of stiff wire, thrown upon a force filter, washed, and dried by suction. The air-dried carvoxime is transferred to a tared glass dish and heated for 1 hour on a water bath, and when cool, weighed. To the weight thus obtained 0.100 Gm. is added, as this is about the quantity lost during heating. From the weight of the carvoxime that of the carvone may be readily calculated, 164.67 parts of the former corresponding to 149.66 parts of the latter, or the weight of carvoxime obtained, expressed in Gm., when multiplied by 0.9088, gives the weight of the equivalent amount of carvone."

Oil of caraway is essentially a mixture of the ketone carvone—of which it contains from 50 to 60 per cent.—with a terpene formerly called *carvene* but now recognized to be d-limonene. Traces of carvacrol have been also reported. The carvone can be isolated from the oil and prepared in a pure state by taking advantage of the formation of a crystalline compound of carvone and hydrogen sulphide, which can then be decomposed by treatment with alcoholic potassium hydroxide.

Oil of caraway is used to impart flavor to medicines, and to correct their nauseating and griping effects.

Gmeiner (*B. Their. W.*, 1909, p. 695) recommends the use of oil of caraway in the treatment of *scabies*. He employs a solution in castor oil containing five parts of alcohol and oil of caraway in seventy-five parts of castor oil.

Dose, from one to five minims (0.06–0.3 cc.).

OLEUM CARYOPHYLLI. U. S., Br.

OIL OF CLOVE Ol. Caryoph. [Clove Oil Oil of Cloves]

"The volatile oil distilled from the dried flower-buds of *Caryophyllus aromaticus* Linné (Fam. *Myrtaceæ*). Oil of Clove yields not less than 82 per cent. by volume of eugenol $[C_{10}H_{12}O_2]$." *U. S.* "Oil of Cloves is the oil distilled from Cloves." *Br.*

Huile volatile de Girofle, *Fr. Cod.;* Oleum Caryophyllorum, *P. G.;* Nelkenöl, Eugenol, *G.;* Essenza di garofani, *It.;* Esencia de clavo, *Sp.*

This oil is obtained by distilling cloves with water, to which it is customary to add common salt, in order to raise the temperature of ebullition, and the water should be repeatedly distilled from the same cloves, in order completely to exhaust them. Scharling has found advantage from the application of superheated steam to the distillation of this oil. (*P. J.*, xi, 469.) It is essential also to use the same water over and over again, in order to avoid loss by the solution of the oil in the water. The product of good cloves is about one-fifth or one-ninth of their weight. The oil was formerly brought from Holland or the East Indies, but since the introduction of the Cayenne cloves into our markets the reduced price and superior freshness of the drug have rendered the distillation of oil of clove profitable in this country, and the best now sold is of domestic extraction.

Description and Physical Properties.—"A colorless or pale yellow liquid, becoming darker and thicker by age or exposure to the air, and having the characteristic odor and taste of clove.

"The Oil is soluble in 2 volumes of 70 per cent. alcohol, by volume. Specific gravity: 1.038 to 1.060 at 25° C. Optical rotation: does not exceed –1° 10′ in a 100 mm. tube at 25° C. Refractive index: 1.5300 to 1.5350 at 20° C. The Oil meets the requirements of the test for *heavy metals in volatile oils.* A solution of the recently distilled oil in 70 per cent. alcohol (1 in 2) is slightly acid to moistened blue litmus paper. Shake 1 cc. of the Oil with 20 cc. of hot distilled water: the water shows not more than a scarcely perceptible acid reaction with blue litmus paper. Cool the mixture, and pass the aqueous layer through a wetted filter: the clear filtrate, with 1 drop of ferric chloride T. S. yields only a transient, grayish-green color, but not a blue or violet color (*phenol*).

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light.

"**Assay.**—Place 10 cc. of Oil of Clove, measured from a pipette, in a 100 cc. cassia flask, add 50 cc. of potassium hydroxide T.S., shake the mixture for five minutes, and heat it for ten minutes in a bath containing boiling water. Remove it from the bath, and cool to room temperature. When the liquids have separated completely, add sufficient potassium hydroxide T.S. to raise the lower limit of the oily layer within the graduated portion of the neck, and note the volume of the residual liquid. This measures not more than 1.8 cc., indicating the presence of not less than 82 per cent. by volume of eugenol." *U. S.*

"Colorless or pale yellow when fresh, darkening with age and on exposure to air. Odor and taste those of Cloves. Specific gravity 1.047 to 1.065; *refractive index* at 25° C. 1.528 to 1.540. Soluble in 3 parts of *alcohol* (70 per cent.), the solution yielding a blue color with *T. Sol. of ferric chloride.* When 10 millilitres of the Oil are well shaken with 100 millilitres *of solution of sodium hydroxide,* heated on a water-bath in a flask with a narrow graduated neck, and then allowed to stand, the uncombined oil, cooled to 15.5° C., measures not more than 1.5 millilitres (presence of not less than 85 per cent. of eugenol)." *Br.*

Oil of clove is one of the least volatile of the essential oils and requires for congelation a temperature from –17.8° to –20° C. According to the observations of H. C. Wood, Jr. (*J. A. Ph. A.*, 1920, ix, 878), the solubility of this oil in 70 per cent. alcohol corresponds more nearly with that given in the Br. (1 in 3) than that in the U. S. P. (1 in 2).

Oil of clove contains small amounts of vanillin, methyl alcohol and furfurol, but is mainly composed of an unsaturated phenol termed eugenol—which is now an official product (see *Eugenol*)—and its acetic derivative and a sesquiterpene *caryophyllene.* Eugenol acetyl salicylate has also been reported. The eugenol content is the most important criterion of its quality and purity.

For the estimation of eugenol in the form of its crystalline benzoyl compound, see *A. J. P.*, 1892, 26 and 508; also *Schim. Rep.*, April, 1892, 28. The characteristic aromatic odor of oil of clove is due to *methylamylketone*, $CH_3.CO.C_5H_{11}$, which has been isolated by the chemists of Schimmel & Co., and found to be present only in minute quantity. (*Ph. Rev.*, 1897, 115.)

Uses.—By virtue of its local irritant effect oil of clove stimulates peristalsis and is frequently a useful remedy in the treatment of *flatulent colic.* It is also an active local anesthetic and is a favorite remedy for *toothache;* for this purpose a small pledget of cotton is saturated with oil and inserted into the carious cavity. It is a powerful germicide, far exceeding phenol in activity, but is not frequently used for this purpose because of its irritant properties. Eugenol has been used internally in doses of forty-five grains (3 Gm.) *per diem* as an antiseptic antipyretic. Little, however, is known of its physiological action. According to Leubuscher (*W. M. Bl.*, 1889), it is a feeble local anesthetic. Landis (*T. G.*, 1909, xxxiii, 386) has used oil of clove as a stimulant expectorant in *tuberculosis* and *bronchiectasis* with good results.

Dose, from two to six minims (0.12–0.4 cc.).

OLEUM CHAULMOOGRÆ. U. S., Br.

CHAULMOOGRA OIL Ol. Chaulmoog.

"The fixed oil expressed from the seeds of *Taraktogenos Kurzii* King (Fam. *Flacourtiaceæ*). The fixed oil from the seeds of certain species of *Hydnocarpus,* when designated as such and when agreeing in physical and chemical characters with Chaulmoogra Oil, may be used in its place." *U. S.* "Chaulmoogra Oil is the fatty oil expressed from the seeds of Taraktogenos Kurzii, *King.*" *Br.*

Oleum Gynocardiæ, Gynocardia oil, Chaulmugra oil.

Under the name of Chaulmoogra Oil there has long been used in southeastern portions of Asia a semi-solid fat produced from the seeds of a tree known by the natives as *Kalaw.*

It was at one time believed that the chaulmoogra oil was derived from *Gynocardia odorata* R. Br., but Desprez in 1899 demonstrated the fallacy of this belief. In the following year Prain attributed the seeds to *Hydnocarpus heterophylla* Bl., which is more properly known as the *Taraktogenos Kurzii* King. (Fam. *Flacourtiaceæ*). In 1922 J. F. Rock (*Bull.* 1057 *U. S. Dept. Agriculture*) published the results of an extensive exploration through Burma and Assam. He found that the seed sold in Burma as from the kalaw was from the fruit not only of *Taraktogenos Kurzii* but also of *Hydnocarpus castanea* Hf. and Th. and perhaps other allied species. He described the *Taraktogenos* as a large tree reaching a height of from 50 to 60 feet, with a smooth pale yellowish bark. The fruits are about the size of a large orange of a light fawn color and velvety, containing numerous seeds irregularly imbedded in the fleshy pulp. The chaulmoogra seeds are brownish yellow, from one to one and a quarter inches long, more or less angular or flattened, and yield upon expression from 25 to 30 per cent., to ether about 50 per cent. of oil.

The process of extracting the oil as reported by Rock is as follows: The seeds are washed, and after drying in the sun, shelled, crushed and submitted cold to hydraulic pressure. The cold drawn oil is then filtered.

Description and Physical Properties.—"A yellow or brownish-yellow liquid, or, at temperatures below about 25° C., a whitish, soft solid. It has a characteristic odor, and a somewhat acrid taste. Chaulmoogra Oil is sparingly soluble in alcohol; soluble in benzene, chloroform, ether, and in petroleum benzin.

"Specific gravity: about 0.950 at 25° C. The specific rotation $[\alpha]_D$ of Chaulmoogra Oil determined at 25° C., in chloroform, containing about 10 Gm. of the Oil in each 100 cc. of the solution, and using a 100 mm. tube, is not less than + 48° and not more than + 60°.

"Dissolve 1 Gm. of the Oil in 15 cc. of a mixture of equal volumes of alcohol and ether, previously neutralized with tenth-normal sodium hydroxide, using 5 drops of phenolphthalein T.S. as indicator, and titrate the solution with tenth-normal sodium hydroxide to the production of a pink color which persists for fifteen seconds: not less than 1.8 cc. and not more than 5 cc. of tenth-normal sodium hydroxide is required (*free acid*). Saponification value: not less than 196 and not more than 213. Iodine value: not less than 98 and not more than 104.

"Preserve in well-closed containers, in a cool place, protected from light." *U. S.*

The Br. describes it as "a brownish-yellow oil or soft fat. Characteristic odor; taste somewhat acrid. Melting point about 22° to 30° C. Specific gravity at 45° C. about 0.940; *saponification value* 198 to 213; *iodine value* 96 to 104; *acid value* 21 to 27. Soluble in *ether,* in *chloroform,* and in *carbon disulphide;* partially soluble in cold *alcohol* (90 per cent.); almost entirely soluble in hot *alcohol* (90 per cent.)." *Br.*

Constituents.—Oil of Chaulmoogra contains small amounts of palmitin and linolein but is made up chiefly of the glycerides of two acids, which do not belong to any of the common types of fatty acids, chaulmoogric and hydnocarpic acid. For our knowledge of these principles, we are chiefly indebted to F. B. Power and his collaborators (*J. Chem. S.*, 1904, lxxxv and 1905, lxxxvii) whose work has been confirmed and extended by Dean and Wrenshall (*J. Am. C. S.*, 1920, xlii, 2626). Both acids are optically active and differ from the ordinary fatty acids in containing a five atom carbon ring with an unstable hydrogen atom. The acids can be readily converted into the ethyl esters, which seem to possess certain therapeutic advantages over chaulmoogra oil, and the mixture of them is official (see *Æthylis Chaulmoogras*).

Chaulmoogric acid, $C_{18}H_{32}O_2$, forms beautiful crystals which melt at 68.5° C. and have an optical rotatory power of +62.1°. Chaulmoogric acid has also been found by Goulding and Akers (*Proc. Chem. Soc.*, 1913, xxix, 97) in the African *gorli seeds*, from *Oncoba echinata* Oliver (Fam. *Flacourtiaceæ*).

Hydnocarpic acid, $C_{16}H_{28}O_2$, also crystallizable, melts at 60° C. and has an optical rotation of +68°.

Sir Leonard Rogers (*Ind. Med. Gaz.*, 1919, liv, p. 165; *Pract.*, 1921, cvii, p. 77) introduced the sodium salts of the fatty acids under the names of *sodium gynocardate* (more properly *sodium chaulmoograte*) and *sodium hydnocarpate*, these having the advantage of being water soluble. He also employed *sodium morrhuate* which, however, is prepared from the unsaturated fatty acid of cod liver oil, not chaulmoogra. (See *Oleum Morrhuæ.*)

It is stated that the seeds of the *Hydnocarpus Wightiana* Blume and of the *H. anthelmintica* Pierre under the name of *lukrabo* are also employed for similar purposes to the chaulmoogra. According to Power (*J. Chem. S.*, 1905, lxxxvii, p. 884), this oil is very similar both in physical properties and chemical composition to the true chaulmoogra oil.

The *Oil of Gynocardia* is optically inactive and contains none of the acids peculiar to the genuine chaulmoogra oil. It consists of glycerides of linolic, palmitic, linolenic, isolinolenic and oleic acids and a phytosterol, as well as a cyanogenetic glucoside, *gynocardin*, $C_{13}H_{19}O_9N$, which resembles amygdalin and which is associated in the seeds with an enzyme, gynocardase. (Power, *J. Chem. S.*, 1905, lxxxvii.)

Uses.—Chaulmoogra oil has been used by the natives of India since time immemorial. An Indian legend relates that a King of Benares, by the name of Rama, some 3000 years ago, afflicted with leprosy retired to the jungles, where he lived largely on the fruit of the Kalaw tree and became cured of his leprosy. In England it is very widely used as a counter-irritant application in *bruises, sprains*, and similar local inflammations both of man and beast as well as in *open sores* and *wounds*. Its most important use, however, is in the treatment of *leprosy*. There seems to be little doubt that it is the most useful remedy known for this intractable infection, indeed many authorities have claimed that it will often produce complete and permanent cures. It should be used freely both internally and externally. Donato (*Leprosy in the Philippines and Its Treatment*, Manila, 1915) believes that its action is due to the stimulation of leucocytosis, but Walker and Sweeny (*J. Inf. D.*, 1920, xxvi) find that it has a powerful germicidal effect on the lepra bacillus. Although the experience of the ancient Indians would seem to demonstrate that the absorption from the alimentary tract can take place sufficiently to exert some beneficial action, all recent writers have preferred the intramuscular injection. The Heiser formula for this injection, at one time largely employed, was as follows: Resorcin 4 Gm., camphor 6 Gm., olive oil 60 cc., chaulmoogra oil 60 cc.; of this solution 1 cc. weekly is the beginning dose, the amount of the injections being gradually increased. Since the work of Power on its chemistry the crude drug has been largely abandoned in favor of the mixed ethyl esters of hydnocarpic and chaulmoogric acids. The advantage of these esters appears to be chiefly in their fluidity. The sodium salts of these acids have also been employed by a number of investigators with favorable results (see *Indian Med. Gaz.*, 1920, lv, pp. 121 to 134). For extensive bibliography of chaulmoogra see Morrow, Walker and Miller (*J. A. M. A.*, 1922, lxxix, 434).

On the ground that both the lepra bacillus and tubercle bacillus are acid-fast organisms, various authors have experimented with the effects of chaulmoogra oil in *tuberculosis*. Kolmer, Davis and Jaeger (*J. Inf. D.*, 1921) found that the oil had no destructive action on the tubercle bacillus and Voegtlein (*J. A. M. A.*, 1921, lxxvii, 1017) found that it was of no value in experimental tuberculosis in the guinea pig. Although some benefit has been reported from the local application in *tuberculous ulcers of the larynx* (see Peers and Shipman, *J. A. M. A.*, 1922, lxxix, 461) it does not appear probable that the drug has any real curative value in tuberculous diseases.

Read (*J. P. Ex. T.*, 1924, xxiv, p. 221) has studied the toxic effects of chaulmoogra on dogs and rabbits. In the former whether given by mouth or by injection it causes vomiting and loss of appetite, which appears to be chiefly of central origin. Large doses also have a marked hemolytic effect. In fatal intoxications there were fatty changes of the liver and evidences of irritation of the kidneys. As far as we know serious poisoning in human beings has not been reported except two cases of fatty embolism of the lung reported by Castel, from hypodermic injection.

Dose, five to ten minims (0.3–0.6 cc.) gradually increased to one fluidrachm (3.75 cc.).

Off. Prep.—Unguentum Chaulmoogræ, *Br.*

OLEUM CHENOPODII. U. S.

OIL OF CHENOPODIUM Ol. Chenopod.
[Oil of American Wormseed]

"The volatile oil distilled with steam from the fresh, over-ground parts of the flowering and fruiting plant of *Chenopodium ambrosioides* var. *anthelminticum* (Linné) A. Gray (Fam. *Chenopodiaceæ*). Oil of Chenopodium yields not less than 65 per cent. of ascaridol [$C_{10}H_{16}O_2$]." *U. S.*

Huile volatile d'Ansérine vermifuge, *Fr. Cod.*; Essence de Chénopode anthelmintique, *Fr.*; Amerikanisches Wurmsamenöl, Chenopodiumöl, *G.*

For description of the plant from which this oil is derived see *Chenopodium*, Part II. The oil is largely distilled in Maryland. It is of a light-yellow color when recently distilled, but becomes deeper yellow and even brownish by age. Its reaction is neutral. It has in a high degree the peculiar odor of the plant.

Description and Physical Properties.—"A colorless or pale yellowish liquid, having a peculiar, disagreeable odor, and a bitter, burning taste.

"The Oil is soluble in not more than 8 volumes of 70 per cent. alcohol, by volume. Specific gravity: 0.955 to 0.980 at 25° C. Optical rotation: varies from –4° to –10° in a 100 mm. tube at 25° C. Refractive index: 1.4723 to 1.4770 at 20° C. The Oil meets the requirements of the test for *heavy metals in volatile oils.*

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Assay.—"Place 10 cc. of Oil of Chenopodium, measured from a pipette, in a 100 cc. cassia flask, add 50 cc. of a solution of acetic acid, made by diluting 60 cc. of glacial acetic acid with distilled water, to measure 100 cc. Shake the mixture well, add sufficient of the acetic acid solution to raise the lower limit of the oily layer within the graduated portion of the neck, and allow the liquids to separate, rotating the flask from time to time. Note the volume of the oily layer. It measures not more than 3.5 cc., indicating the presence of not less than 65 per cent. by volume of ascaridol." *U. S.*

This assay process was suggested by Nelson (*J. A. Ph. A.*, 1921, x, 836).

In 1907 Kremers, in attempting the fractional distillation of oil of chenopodium, found that a large part consisted of a liquid which could not be distilled because it underwent an explosive decomposition when heated. Schimmel and Co. (*Schim. Rep.*, April, 1908) succeeded in isolating this fraction by distillation at reduced pressure and gave to it the name of ascaridol. *Ascaridol,* which makes up from 45 to 70 per cent. of the oil, is an unstable organic peroxide which, according to Wallach, is neither an alcohol, ketone, aldehyde or acid. It has the formula $C_{10}H_{16}O_2$: a specific gravity of 0.9985 at 20° C. and is lævorotatory. It is liable to explode with considerable violence, either when heated or by treatment with certain organic acids. Henry and Paget (*J. Chem. Soc.*, 1921, cxix, 1714) find the oil consists of at least 60 per cent. of ascaridol with about 5 per cent. of the corresponding glycol and 30 to 40 per cent. of a mixture of hydrocarbons made up approximately of cymene 15 per cent., α-terpinene, and a new lævorotatory terpene 10 per cent. They report also minute traces of butyric acid and less than 0.5 per cent. of methyl salicylate.

The conclusion of Nelson (*J. Am. C. S.*, 1920) that ascaridol is the active principle of the oil of chenopodium, although called into question by Hall and Hamilton (*J. P. Ex. T.*, 1918, xi, 231) has been confirmed by Molloy (*J. P. Ex. T.*, 1923, xxi, 390) and by Smillie and Pessoa (*J. P. Ex. T.*, 1924, xxiv, 359) and is generally accepted.

Uses.—The oil of chenopodium is used in medicine almost exclusively as an anthelmintic. Although it has been official in the Pharmacopœia for many years, it owes its modern popularity to the investigations of Brunning. (*Z. E. P. T.*, 1905, i, and 1906, iii, p. 564). This author showed that one part in five thousand paralyzed, although it did not kill, the round worm of dogs, and that one part in two hundred had a distinct antiseptic action. In mammals, if given in sufficient dose, it depresses the spinal cord and finally kills by arrest of respiration. According to Salant and Livingston (*A. J. Phys.*, 1915, xxxviii) the oil of chenopodium in doses of 0.02 cc. per kilo, or more, produces a lowering of the blood pressure through a cardiac action and diminution in the amplitude and rate of respiration.

Since the investigations of Brunning oil of chenopodium has been widely used in all sorts of intestinal parasites and with generally satisfactory results. Originally it was employed chiefly against the *ascarides* and still remains the remedy of choice against this parasite, but both Schuffer and Verwoort (*M. M. W.*, 1913, lx, p. 129) and Rousis and Bishop (*J. A. M. A.*, 1920, lxxiv, p. 1768), from comparative studies, range it as more efficient than thymol in uncinariasis. Several authors, including Barnes and Cort (*J. A. M. A.*, August 3, 1918), have also found it useful in the treatment of *amebic dysentery.*

While with proper care oil of chenopodium is a relatively safe anthelmintic, it is not a drug to be used carelessly. In a not inconsiderable proportion of cases mild toxic symptoms occur and Levy (*J. A. M. A.*, 1914, lxiii, p. 1946) has collected from the literature twelve cases of serious poisoning of which nine ended fatally. The smallest dose in this series was four drops three times a day for two days, which caused death in a baby one year old. In another case a child of two recovered from a dose of two teaspoonfuls given in the course of one afternoon. The symptoms of poisoning by oil of chenopodium—which may not appear for several hours after taking the oil—are nausea, vomiting, headache followed by drowsiness, ringing in the ears, and sometimes deafness. In the fatal cases there develop coma and convulsions.

The experiments of Zeigler (*Interstate Med. Jour.*, October, 1917) and of Salant (*J. A. M. A.*, 1917, lxix, p. 2016) show very distinctly an accumulative tendency in the toxicity of this drug. In Salant's experiments an increased sensitiveness to a second dose persisted 5 to 9 days after the first dose. Oil of chenopodium differs from most vermifuges in that its use should not be preceded with a period of starvation. There is no evidence that this preliminary fasting enhances the vermicidal efficiency of the oil and the original observations of Salant that fasting or poorly-nourished animals are more susceptible to the toxic effects have been abundantly confirmed for human beings.

The physiological studies of Salant and of Zeigler show that its toxic effects are partly the result of local irritation, not only of the alimentary tract, but also of the eliminating organs especially of the kidney and liver, and partly due to a direct depressant effect on the circulation and respiration. In the milder cases of chenopodium poisoning the symptoms usually pass off within a few hours spontaneously; in the severe cases circulatory stimulants, especially digitalis, epinephrin and atropin, are recommended.

The *dose* and method of administration of oil of chenopodium differs according to the weight, age and nutritive state of the patient as well as with the type of infection. It is most conveniently administered enclosed in gelatin capsules and should be always followed with a purgative dose of castor oil. For round worm infestation two or three doses of from 3 to 5 minims (0.2–0.3 cc.) each at intervals of one or two hours may be administered to well-nourished adults but in hook worm considerably larger quantities have been used. For children and poorly-nourished persons the doses should be reduced in proportion to the weight. It is important that the dose should be measured by minims and not by drops as the drop is approximately equal to one-half minim.

OLEUM CINNAMOMI. U. S., Br.

OIL OF CINNAMON Ol. Cinnam.
[Oleum Cassiæ, U. S. IX]

"The volatile oil distilled from the leaves and twigs of *Cinnamomum Cassia* (Linné) Blume (Fam. *Lauraceæ*), rectified by steam distillation. Oil of Cinnamon yields not less than 80 per cent. by volume of cinnamic aldehyde [C_9H_8O]." *U. S.* "Oil of Cinnamon is the oil distilled from Cinnamon Bark." *Br.*

Essence de Cannelle, Huile volatile de Cannelle, *Fr.;* Oleum Cinnamomi, *P. G.;* Zimmtöl, Zimmtkassienöl, *G.;* Essenza di Cannella, *It.*

There are two oils of cinnamon in commerce, one procured from the Ceylon cinnamon, the other from the Chinese cinnamon, and often distinguished by the name of *oil of cassia.* There is no essential difference in the two oils, and that of the Chinese cinnamon, as much the cheaper and more abundant of the two, will probably continue to be generally employed, notwithstanding that the Ceylon product has the finer flavor. The U. S. P. X and the German Pharmacopœia recognize as oil of cinnamon only that obtained from cassia. The British Pharmacopœia and French Codex make Oil of Ceylon Cinnamon official. The oil of the Br. has a lower specific gravity and a lower content of cinnaldehyde than the U. S.

Oil of Chinese Cinnamon.—*Cassia oil* is imported from Canton and Singapore it is pale yellow, becoming red with age. Its flavor is similar to that of the Ceylon oil, though inferior, and it commands a much lower price.

The researches of Schimmel & Co. seem to show that the Chinese cassia oil of commerce is distilled from the leaves, leaf-stalks, and young twigs of the cassia plant—probably with broken bark and various refuse products from the tree; also that much of the oil is adulterated with rosin and petroleum. Besides cinnamic aldehyde cinnamyl acetate and cinnamic acid are also present as well as small amounts of phenylpropyl acetate and orthocumaric aldehyde.

In the distillation by Schimmel & Co. the various portions of the cassia plant obtained from China yielded the following results. 1. Cassia bark (*Cassia lignea* of commerce): yield of essential oil 1.5 per cent.; aldehyde in oil 92 per cent.; sp. gr. 1.035. 2. Cassia buds (*Flores Cassiæ* of commerce): yield of essential oil 1.550 per cent.; aldehyde in oil 80.4 per cent.; sp. gr. 1.026. 3. Cassia budsticks: yield of essential oil 1.64 per cent.; aldehyde in oil 92 per cent.; sp. gr. 1.046. 4. Cassia leaves, leaf-stalks, and young twigs mixed: yield of essential oil 0.77 per cent.; aldehyde in oil 93 per cent.; sp. gr. 1.055. Zeller states that oil of cassia is heavier, less liquid, and sooner rendered turbid by cold, and that in the Ceylon oil, iodine dissolves rapidly, with a considerable increase of heat, and the production of a tough residue, like an extract, while in oil of cassia and reaction is slow, quiet, and with little heat, and the residue is soft or liquid.

Description and Physical Properties.—"A yellowish or brownish liquid, becoming darker and thicker by age or exposure to the air, and having the characteristic odor and taste of cassia cinnamon.

"The Oil is soluble in an equal volume of alcohol, in 2 volumes of 70 per cent. alcohol, by volume, and in an equal volume of glacial acetic acid. Specific gravity: 1.045 to 1.063 at 25° C. Optical rotation: varies from $+1°$ to $-1°$ in a 100 mm. tube at 25° C. Refractive index: 1.6020 to 1.6060 at 20° C. A solution of the recently rectified oil in 70 per cent. alcohol (1 in 2) is slightly acid to moistened blue litmus paper. The Oil meets the requirements of the test for *heavy metals in volatile oils.* Shake 2 cc. of the Oil in a test tube with from 5 to 10 cc. of purified petroleum benzin, allow the liquids to separate, and decant the benzin layer into another test tube: this liquid is but slightly colored, and does not assume a green color upon shaking with an equal volume of copper acetate solution (1 in 1000) (*rosin* or *rosin oils*). Rinse the interior surface of a well-cleaned, 1000 cc. beaker with distilled water, and pass the washings through a small filter until the addition of 1 drop of silver nitrate T.S. to a portion of the filtrate, acidulated with 1 drop of nitric acid, shows no turbidity. Place 3 or 4 drops of the Oil on a clean watch glass supported on a triangle, ignite, and immediately cover with the moistened beaker. Wash the products of combustion from the sides of the beaker through the washed filter with from 10 to 20 cc. of distilled water, and acidulate the filtrate with 1 drop of nitric acid: the addition of 1 drop of silver nitrate T.S. produces no turbidity (*chlorinated products*).

"Preserve in well-stoppered, amber-colored bottles, in a cool place protected from light.

"**Assay.**—Proceed as directed under *Oleum Cari,* using 10 cc. of Oil of Cinnamon, measured from a pipette. The volume of the residual oily layer measures not more than 2 cc., indicating the presence of not less than 80 per cent. by volume of cinnamic aldehyde." *U. S.*

H. C. Wood, Jr. (*J. A. Ph. A.*, 1920, ix, 878) finds the solubility of oil of cinnamon in 70 per cent. alcohol is much less than that stated in the Pharmacopœia.

Oil of Ceylon Cinnamon.—Oil of cinnamon of Ceylon is distilled from inferior grades of bark, of insufficient value to pay the export duty. The following account of the method of extraction is given by Marshall. The bark, having been coarsely powdered, is macerated for two days in sea water, and then submitted to distillation. A light and a heavy oil come over with the water, the former of which separates in a few hours and floats upon the surface, the latter falls to the bottom of the receiver, and continues to be deposited for ten or twelve days. In future distillations, the saturated cinnamon water is employed with sea water to macerate the cinnamon. Eighty pounds of the freshly prepared bark yield about 2.5 ounces of the lighter oil, and 5.5 of the heavier.

Oil of Ceylon cinnamon is of a light-yellow color, becoming deeper by age, and ultimately red. Pereira stated that the London druggists redistilled the red oil, and thus obtained two pale-yellow oils, one lighter and the other heavier than water, with a loss of about 10 per cent. in the process. The oil has the flavor of cinnamon, and when undiluted is excessively hot and pungent. It is said sometimes to have a peppery taste, ascribable to an admixture of the leaves with the bark in the preparation of the oil. Oil of Ceylon cinnamon has a slightly acid reaction. Cinnamic aldehyde is the chief constituent, but eugenol is present to the extent of over 5 per cent., and phellandrene has also been reported.

The British Pharmacopœia gives the following description and tests: "Yellow when freshly distilled, gradually becoming reddish. Odor and taste those of Cinnamon Bark. Specific gravity 1.000 to 1.030; *optical rotation* –0.5° to –1°; *refractive index* at 25° C. 1.565 to 1.580. Soluble in from 3 to 4 parts of *alcohol* (70 per cent.). 1 drop dissolved in 5 millilitres of *alcohol* (90 per cent.) assumes a pale green, but not a blue or brown coloration, on the addition of 1 drop of *T. Sol. of ferric chloride* (absence of cinnamon leaf oil and cassia oil). Contains from 55 to 65 per cent. of cinnamic aldehyde as determined by the following test: To 10 millilitres of the Oil add 70 millilitres of an aqueous solution (1 in 5) of *sodium sulphite* and sufficient *solution of phenolphthalein* to give a well marked pink coloration. Heat the mixture on a water-bath, shake well, and neutralise with *acetic acid* diluted with twice its volume of *water;* repeat the heating and neutralisation until no further pink coloration is developed, the time occupied being from thirty to forty-five minutes. The oily layer which separates on standing, cooled to 15.5° C., measures not more than 4.5 or less than 3.5 millilitres (presence of 55 to 65 per cent. of cinnamic aldehyde)." *Br.*

The *cinnamon leaf oil,* as formerly imported into Great Britain, was of two kinds, one containing a considerable quantity of a fatty fixed oil, perhaps cinnamon-suet from the fruit, the other a pure volatile oil. The oil was said to be obtained by distilling the leaves after maceration in sea water. Cinnamon leaf oil contains much eugenol and very little cinnamic aldehyde, safrol and benzaldehyde being present as minor constituents. It resembled the oil of clove and pimento in sensible properties, having a brownish color, a penetrating, fragrant odor, and a very pungent taste. Schimmel & Co. found it to have a sp. gr. 1.056 to 1.060, and contained 87 per cent. of eugenol, and about 0.1 per cent. of cinnamic aldehyde.

When exposed to the air oil of cinnamon absorbs oxygen, and is slowly converted into cinnamic acid, two distinct resins, and water. Of the two resins, one is soluble both in hot and in cold alcohol; the other readily in the former, but sparingly in the latter. Oil of cinnamon is almost wholly converted by nitric acid, slowly added, into a crystalline mass, producing a compound of the oil and the acid. These several facts are explained when it is found that oil of cinnamon contains from 75 to 90 per cent. of *cinnamic aldehyde.*

Cinnamic aldehyde, C_9H_8O, was official in the U. S. VIII under the title *Cinnaldehydum.* "It is a colorless liquid, having a cinnamon-like odor and a sharp, burning, aromatic taste. Specific gravity about 1.047 at 25° C. Optically inactive. It boils at about 250° C., with partial decomposition. Cinnamic aldehyde should partially solidify when the temperature is reduced by a freezing mixture of ice and salt and should melt again at 7.5° C. It is sparingly soluble in water, soluble in all proportions in alcohol, ether, and fixed and volatile oils." *U. S. VIII.* By moderate oxidation it yields the corresponding cinnamic acid, but by more energetic oxidation yields benzoic acid. Cinnamic aldehyde has been produced artificially by Strecker from styrone, a derivative from styrax (see *Styrax*), and more recently from benzaldehyde and acetaldehyde, a mixture of which is saturated with hydrochloric acid gas, when a condensation takes place, as follows:

$$C_6H_5COH + CH_3COH = C_6H_5.CH : CH.CHO + H_2O$$

Ordinary sodium hydroxide will also bring about the reaction between the two aldehydes, and is to be preferred to hydrochloric acid for this purpose.

Uses.—Although a very powerful germicide the oil of cinnamon, because of its irritant properties, is rarely used in medicine as an antibacterial. It has the cordial and carminative properties of cinnamon, without its astringency, and is much employed as an adjuvant to other medicines, the taste of which it corrects or conceals, while it conciliates the stomach. As a powerful local stimulant, it is sometimes prescribed in *gastrodynia, flatulent colic,* and *gastric debility.* Drummond (*B. M. J.,* 1918) states that it is useful as an internal remedy in *coryza.* Mitscherlich found six drachms to kill a moderate-sized dog in five hours, and two drachms one in forty hours. Inflammation and corrosion of the gastro-intestinal mucous membrane were observed after death.

Dose, one to three minims (0.06–0.2 cc.).

OLEUM COPAIBÆ. Br.

OIL OF COPAIBA

Oil of Copaiva; Oleum Balsami Copaivæ; Essence de Copahu, *Fr.;* Copaivaöl, *G.*

Oil of copaiba is no longer official in the U. S. P. The oil constitutes from one-third to one-half of the Maracaibo copaiba and from one-half to three-fourths of the Para copaiba. It is prepared largely by steam distillation. As it first comes over it is colorless, but the later product is of a fine greenish hue. By redistillation it may be rendered wholly colorless. It has the odor and taste of copaiba, a neutral reaction, solidifies, partly crystalline, at –26.1° C. (Gmelin), is soluble in ether and in an equal weight of absolute alcohol. The oil consists chiefly of caryophyllene. "Colorless or pale yellow. Odor and taste those of Copaiba. Specific gravity 0.896 to 0.910; *optical rotation* –7° to –35°; *refractive index* at 25° C. 1.494 to 1.500. Distils between 250° and 275° C. A solution of 1 millilitre of the Oil in 5 millilitres of *glacial acetic acid* does not develop more than a faint violet coloration on the addition of 4 drops of *nitric acid* (absence of gurjun oil). When distilled in a vacuum the first 10 per cent. of the distillate has an *optical rotation* lower than that of the original Oil (absence of oil of African copaiba)." *Br.*

From its want of oxygen, it answers even better than naphtha for preserving potassium, a fact first observed by Durand, of Philadelphia. It dissolves sulphur and phosphorus.

Its effects on the system are those of copaiba. From the experiments of C. Mitscherlich, it is one of the least injurious of the volatile oils to the animal system, six drachms of it having been introduced into the stomach of a rabbit without causing death. Externally it produces much less irritation than does oil of turpentine. It may be used for the same purposes as copaiba.

Dose, five to fifteen minims (0.3–0.9 cc.).

OLEUM CORIANDRI. U. S., Br.

OIL OF CORIANDER Ol. Coriand. [Coriander Oil]

"The volatile oil distilled from the dried ripe fruit of *Coriandrum sativum* Linné (Fam. *Umbelliferæ*)." *U. S.* "Oil of Coriander is the oil distilled from Coriander Fruit." *Br.*

Essence de Coriandre, *Fr.;* Korianderöl, *G.*

This oil may be obtained by distillation with water from the bruised fruit in the manner directed in the U. S. Pharm. 1870, for volatile oils. The average yield of oil from coriander is from 0.5 to 1 per cent. It boils at about 150° C., and consists chiefly (45 to 65 per cent.) of *coriandrol,* $C_{10}H_{18}O$. According to Semmler (*B. Chem. G.,* xxiv, 206), coriandrol boils between 194° and 198° C., is optically dextrogyrate, and has a sp gr. of 0.8679 at 20° C. Coriandrol is now known as dextrogyrate linalool. The other constituents of oil of coriander are pinene, terpinene, decyl aldehyde, geraniol and borneol. The characteristic odorous principle, or principles, is not known. (See *Schim. Rep.,* April, 1892.)

Description and Physical Properties.—"A colorless or pale yellow liquid, having the characteristic odor and taste of coriander.

"The Oil is soluble in 3 volumes of 70 per cent. alcohol, by volume. Specific gravity: 0.863 to 0.875 at 25° C. Optical rotation: varies from +8° to +13° in a 100 mm. tube at 25° C. Refractive index: 1.4630 to 1.4760 at 20° C. Oil of Coriander meets the requirements of the test for *heavy metals in volatile oils.*

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

"Colorless or pale yellow. Odor and taste those of Coriander Fruit. Specific gravity 0.870 to 0.885; *optical rotation* +8° to +14°; *refractive index* at 25° C. 1.463 to 1.467. Soluble in 3 parts of *alcohol* (70 per cent.)." *Br.*

Oil of coriander is extensively adulterated with colorless rectified oil of orange, which can be detected by its insolubility in 90 per cent. alcohol, in which pure coriander oil dissolves in every proportion; equal parts of oil of orange and 90 per cent. alcohol make a turbid mixture. The oil has the medicinal properties of the fruit, and, like the aromatic oils generally, may be used to cover the taste or correct the nauseating or griping properties of other medicines. It has the great advantage of being more stable and retaining its agreeable odor longer than any other oil of its class.

Dose, one to three minims (0.06–0.2 cc.).

Off. Prep.—Spiritus Aurantii Compositus, *U. S.;* Elixir Aromaticum (from Spirit), *U. S.*

OLEUM CUBEBÆ. Br.

OIL OF CUBEBS

"Oil of Cubebs is the oil distilled from Cubebs." *Br.*

Oleum Cubebarum; Cubeb Oil; Huile volatile (Essence) de Cubèbe, *Fr.;* Kubebenöl, *G.*

The oil is obtained from cubeb by grinding the berries, and then distilling with water. The yield is from 10 to 18 per cent. When recently distilled from the fruit, the oil is somewhat greenish, becoming yellowish by age, but when carefully redistilled it is colorless. It has the odor of cubeb, a warm, aromatic, camphoraceous taste, and a neutral reaction, is of a consistence approaching that of almond oil, is lighter than water, and when exposed to the air is said to thicken without losing its odor.

"Colorless, pale green, or greenish-yellow. Odor and taste those of Cubebs. Specific gravity 0.910 to 0.930; *optical rotation* −25° to −40°; *refractive index* at 25° C. 1.486 to 1.500. Not less than 60 per cent. distils between 250° and 280° C." *Br.*

The oil consists chiefly of sesquiterpenes which distil over between 250° and 280° C., one of which is cadinene, $C_{15}H_{24}$, with some dipentene, and probably pinene or camphene. Upon standing, it sometimes deposits rhomboidal prismatic crystals of a stearopten. The *camphor of cubeb* is a crystalline substance having the formula $C_{15}H_{26}O$, is fusible at from 66° to 68° C., and volatilizes without change at from 148° to 150° C. It appears to occur only in old specimens of the oil and is probably a product of the oxidation of a sesquiterpene.

The oil has the aromatic properties of cubeb, but it is much less pungent than the fluidextract or the oleoresin and does not, therefore, completely represent the crude drug. It may, however, often be advantageously substituted for the powder, the dose to be gradually increased until its effects are obtained, or until it proves offensive to the stomach. It may be given suspended in water by means of sugar, in the form of emulsion, or enclosed in capsules of gelatin.

Dose, five to fifteen minims (0.3–0.9 cc.).

OLEUM EUCALYPTI. U. S., Br.

OIL OF EUCALYPTUS Ol. Eucalypt.

[Eucalyptus Oil]

"The volatile oil distilled from the fresh leaves of *Eucalyptus Globulus* Labillardière, and from some other species of *Eucalyptus* (Fam. *Myrtaceæ*). Oil of Eucalyptus yields not less than 70 per cent. of eucalyptol (cineol) [$C_{10}H_{18}O$]." *U. S.* "Oil of Eucalyptus is the oil distilled from the fresh leaves of Eucalyptus Globulus, *Labill.,* Eucalyptus dumosa, *A. Cunn.,* and other species of Eucalyptus, and rectified." *Br.*

Oil of Eucalyptus Globulus; Huile volatile (Essence) de Eucalyptus, *Fr. Cod.;* Eucalyptusöl, *G.;* Esencia de eucalipto, *Sp.*

Various species of the genus *Eucalyptus,* grown in Australia and Algeria, yield volatile oils in sufficient quantity to be commercial products. There are more than one hundred different kinds of eucalyptus oil known. These are classified according to the predominant constituent as follows: Eucalyptus-pinene oils of which fifty-one varieties have been described; eucalyptus-pinene oils containing no phellandrene, of which there are seven varieties; pinene-sesquiterpene oils, containing no phellandrene, of which there are fourteen varieties; oils containing *aromadendral* but no phellandrene of which there are nine varieties; phellandrene containing oils with *piperotone* present, of which there are eleven varieties; phellandrene containing oils with sesquiterpene present, of which there are twenty-two varieties and unclassified oils containing geraniol and its acetic ester, citral, citronellal, etc., of which there are four varieties.

Aromadendrol is an aldehyde-like body which Baker and Smith reported along with *australol,* a phenolic compound. (*Ph. Ztg.,* 1922, lxvii, 611.) *Cryptol,* a lævorotatory compound, is responsible for the optical activity of certain eucalyptus oils according to Read and Smith. These oils differ radically in therapeutic properties (see *Eucalyptus*). The oils officially intended are those containing preponderating proportions of cineol. There are very few species which produce an oil as rich in cineol as required by the U. S. X (70 per cent.) but the standard of the Br. is considerably lower (55 per cent.). Oils reaching the latter figure have been distilled from the *E. incinata* Turcz., and *E. cneorifolia* DC., in addition to those named by the Pharmacopœia. The oils from *E. odorata* Behr. and *E. amygdalina* Labill. also yield oils fairly rich in cineol but rarely, if ever, reach the proportion official.

Description and Physical Properties.—"A colorless or pale yellow liquid, having a characteristic, aromatic, somewhat camphoraceous odor, and a pungent, spicy, cooling taste.

"The Oil is soluble in 4 volumes of 70 per cent. alcohol, by volume. Specific gravity: 0.905 to 0.925 at 25° C. Optical rotation: varies from −10° to +10° in a 100 mm. tube at 25° C. Refractive index: 1.4600 to 1.4690 at 20° C. A solution of the recently distilled Oil in 70 per cent. alcohol (1 in 4) is neutral to moistened litmus paper. Mix 2 cc. of Oil of Eucalyptus with 4 cc. of glacial acetic acid, and gradually add 3 cc. of a 20 per cent. aqueous solution of sodium nitrite. When the mixture is gently stirred with a glass rod, crystals of phellandrene nitrite do not form (*eucalyptus oils containing large amounts of phellandrene*). The Oil meets the requirements of the test for *heavy metals in volatile oils.*

"The congealing point of Oil of Eucalyptus does not fall below −15.4° C. as determined by the method described on page 1536.

"Preserve it in well-stoppered amber-colored bottles in a cool place protected from light." *U. S.*

"Colorless or pale yellow. Aromatic, camphoraceous odor; taste pungent, leaving a sensation of cold. Specific gravity 0.910 to 0.930; *optical rotation* −10° to +10°. Soluble in 5 parts of *alcohol* (70 per cent.). Contains not less than 55 per cent. by volume of cineol as determined by the process described under 'Oleum Cajuputi.' When 1 millilitre is mixed with 2 millilitres of *glacial acetic acid* and 5 millilitres of *petroleum spirit,* 2 millilitres of a saturated aqueous solution of *sodium nitrite* being added, and the mixture gently shaken, no crystalline precipitate forms in the upper layer (absence of oils containing much phellandrene)." *Br.*

Assay.—The assay of oil of eucalyptus for its cineol content has long been a matter of research. The earlier methods depended upon fractional distillation, freezing the proper fraction and subsequently weighing the crystallized cineol. Later a method was used in which strong phosphoric acid was added to the oil. This produced a crystalline magma of cineol phosphate, which was collected, pressed between sheets of filter paper and subsequently decomposed with hot water in a graduated tube which enabled the proportion of separated cineol to be read off. This was the test used in the U. S. P. VIII. This test was subsequently changed by the substitution of arsenic acid for the phosphoric acid previously used, the cineol arsenate being believed to be more easily separated and purified. This was known as Turner and Holmes' modification. (*Perf. and Essent. Oil Rec.,* 1915, p. 21.)

Schimmel and Co. later recommended the use of a cassia flask and the absorption of the cineol by a 50 per cent. aqueous solution of resorcinol. Still another method was proposed by Dodge in which potassium permanganate was employed as the reagent.

Parry reviewed the arsenic acid method and condemned it as not satisfactory as to its accuracy.

The U. S. P. Revision Committee, finding no method of assay for cineol that can be considered reliable, has included none in the tenth revision, simply relying on the congealing point of the oil for an approximate idea of its value.

The assay process of the U. S. IX was as follows: "Measure 10 mils of the Oil, from a pipette, into a round-bottom glass dish of 50 mils capacity, which is embedded in finely broken ice. Add 10 mils of arsenic acid T.S. and stir until precipitation is complete. When the mixture ceases to congeal further, allow it to stand for ten minutes in the ice bath. (If at this point a hard mass is formed, add 5 mils of purified petroleum benzin, and mix the mass well before proceeding with the assay.) Then transfer it immediately to a hardened filter paper, about 18.5 cm. in diameter, by means of a pliable horn spatula; spread it evenly over the surface of the paper and lay a second hardened filter paper over the top. Wrap several thicknesses of absorbent or filter paper around the hardened filters, and place the whole between the plates of a press and bring to bear all the pressure possible for about one minute. Change the outside absorbent papers and press again, repeating the operation, if necessary, until the eucalyptol arsenate is apparently dry, and separates readily when touched with a spatula. The pressing is not complete until a hard mass remains which is broken up with difficulty; and usually two changes of filter paper are required, pressing each time for about two minutes; if left too long in the press the compound may decompose. Now, transfer the compound completely by means of the horn spatula to a glass funnel inserted into a 100 mil cassia flask with a neck graduated to 10 mils into tenths. Wash the last portions of the precipitate into the flask with a stream of hot distilled water from a wash bottle, assisting the disintegration with a glass rod, place the flask in boiling water and rotate it until the compound is thoroughly broken up. Then add enough distilled water to cause the eucalyptol to rise into the neck of the flask, cool it to room temperature and read its volume. This volume, multiplied by 10, shows the percentage of eucalyptol (cineol) in the Oil." *U. S. IX.*

Power has modified the test for phellandrene so as to make it more delicate. According to his directions, 1 cc. of the oil is mixed with 5 cc. of petroleum benzin, 1 or 2 cc. of a concentrated solution of sodium nitrite added, and subsequently glacial acetic acid added, a drop or two at a time, with vigorous agitation after each addition. If phellandrene is present in any considerable amount, its crystalline nitrosite, $C_{10}H_{16}(NO)NO_2$, will separate from the benzin solution.

The oil from *Eucalyptus Globulus* contains pinene, $C_{10}H_{16}$, and *eucalyptol* (or *cineol*). Schimmel & Co. also state (*B. Chem. G.,* April, 1888) that they have obtained several of the aldehydes of the fatty series, notably valeraldehyde, and probably butyraldehyde and capronaldehyde, in their distillation of the oil from *Eucalyptus Globulus.*

Eudesmol, $C_{10}H_{16}O$ (possibly a ketone), is the name given to a crystalline camphor obtained from the oil from *E. piperita* Smith, by H. G. Smith and R. T. Baker. It also occurs in the oil from *E. Globulus.* It is isomeric with camphor, but has its oxygen atom combined in a different way.

Whether or not the medicinal virtues of the official oil are due entirely to its cineol is uncertain, but many prefer to use the pure eucalyptol to the oil itself.

Uses.—Oil of eucalyptus is an active germicide, although surpassed in power by many of the other volatile oils. Cineol is probably a less efficient antibacterial agent than oil of eucalyptus. It is absorbed from the intestinal tract, eliminated partially through the breath to which it imparts its odor, and also, as an oxidation product, through the urine to which it gives an odor resembling that of violets.

A number of cases of poisoning from oil of eucalyptus have been reported. Barker and Rowntree (*J. H. H. B.*, 1918, xxix, 215) have collated 29 cases of eucalyptus poisoning of which 7 were fatal. The smallest fatal dose was 3.5 cc. (57 minims), but doses of 5 fluidrachms and in one case 1 fluidounce were recovered from. The most common symptoms were epigastric burning with nausea and usually vomiting; dizziness and muscular weakness also occurred almost uniformly. The skin was pale, or sometimes cyanotic, the extremities cold, pulse rapid and small, pupils generally much contracted; the intellection almost always affected, in most instances the patients were dazed and usually drowsy. In the very severe types delirium was common and occasionally associated with convulsions. One of the earliest symptoms is a feeling of suffocation. The odor of the drug was strong on the breath, often remaining for one or two days, and was sometimes also perceptible in the urine and feces. There are some people with idiosyncrasies in whom ordinary therapeutic doses give rise to dermatitis.

The oil of eucalyptus is used locally as an antiseptic, especially in the treatment of infections of the upper respiratory tract and in certain forms of *skin disease.* Internally it is used as a stimulating expectorant in *chronic bronchitis* and *tuberculosis.* In these conditions it is also frequently given by inhalation; a few drops of the oil may be added to boiling water and the mixed vapors and steam inhaled. It has been especially praised in *asthma,* given internally or preferably by inhalation by means of cigarettes, which may be made by rolling up the dried leaves, or the vapor from boiling water containing the oil may be inhaled. It is also used as a remedy against the *hookworm,* but is probably of inferior value. It possesses also some antiperiodic power and may be used in *malarial fever* when for any reason quinine or methylthionine are not available.

Dose, three to ten minims (0.2–0.6 cc.), best administered in emulsion.

Off. Prep.—Unguentum Eucalypti, *Br.;* Curatio Paraffini, *N. F.*

OLEUM FŒNICULI. U. S.

OIL OF FENNEL Ol. Fœnic. [Fennel Oil]

"The volatile oil distilled from the dried ripe fruit of *Fœniculum vulgare* Miller (Fam. *Umbelliferæ*). If solid material has separated, carefully warm the Oil until completely liquefied and thoroughly mix it before dispensing." *U. S.*

Huile volatile de Fenouil, *Fr. Cod.;* Essence de Fenouil, *Fr.;* Oleum Fœniculi, *P. G.;* Fenchelöl, *G.*

Fennel seeds yield about 2.5 per cent. or, according to Zeller, from 3.4 to 3.8 per cent., of oil. That used in this country is imported.

Description and Physical Properties.—"A colorless or pale yellow liquid, having the characteristic odor and taste of fennel.

"The Oil is soluble in 8 volumes of 80 per cent. alcohol, by volume, and in 1 volume of 90 per cent. alcohol by volume. Specific gravity: 0.953 to 0.973 at 25° C. Optical rotation: varies from +12° to +24° in a 100 mm. tube at 25° C. Refractive index: 1.5280 to 1.5380 at 20° C. A solution of the recently distilled Oil in 80 per cent. alcohol (1 in 8) is neutral to moistened litmus paper. The Oil meets the requirements of the test for *heavy metals in volatile oils.* The congealing point of Oil of Fennel does not fall below 3° C. when determined by the method described on page 1536.

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

It congeals below 10° C. into a crystalline mass—especially if a small crystal of solid anethol be added—separable by pressure into a solid and a liquid portion, the former heavier than water, and less volatile than the latter, which rises first when the oil is distilled. It contains anethol (see *Oleum Anisi*), usually in amounts of about 60 per cent., d-pinene, phellandrene, dipentene, *fenchone,* $C_{10}H_{16}O$ (a liquid ketone), chavicol, anisic aldehyde, and anisic acid. Fenchone is the constituent which when present gives the disagreeable bitter taste to many of the commercial oils. *Schimmel's Report* for April, 1897, mentions limonene as also at times present as a constituent. The proportion of the different ingredients in oil of fennel varies considerably according to its source. Umney (*Proc. A. Ph. A.*, 1897, p. 516) finds that the Japanese oil contains about 75 per cent. of anethol and 10 per cent. of fenchone. The French (sweet or Roman) oil is practically free from fenchone, that from the Russian and Saxon fruits contains from 18 to 22 per cent. of fenchone. It is slightly dextrogyrate.

Dose, three to five minims (0.2–0.3 cc.).

OLEUM GAULTHERIÆ. Br.

OIL OF GAULTHERIA [Oil of Wintergreen]

"Oil of Gaultheria is the oil distilled from the leaves of Gaultheria procumbens, *Linn.*, or from the bark of Betula lenta, *Linn.*" *Br.*

Oil of Teaberry; Huile volatile (Essence) de Winter-green, *Fr. Cod.;* Essence de Gaulthérie, *Fr.;* Wintergrünöl, Bergtheeöl, *G.*

Oil of gaultheria is no longer official in the U. S. P. Under *Methylis Salicylas* the U. S. Pharmacopœia directs that oil of gaultheria and oil of betula or sweet birch may be used.

The volatile oil of gaultheria is largely obtained in the United States by distillation of the plant. It probably does not exist in the plant, but is formed by a reaction between water and a neutral principle analogous to amygdalin, to which Procter has given the name of *gaultherin.* (*A. J. P.*, xv.) This substance, which was called by Schneegans *bétulase,* probably exists in all the numerous plants which yield methyl salicylate on distillation. The oil occurs in various of our native plants, and has been detected in *Polygala paucifolia* Willd., *Spiræa Ulmaria* L., *Spiræa lobata* Jacq., and *Chiogenes hispidula* Torr. and Gray. T. E. de Vrij found it in considerable proportion in the *Gaultheria leucocarpa* Blume. and *G. fragrantissima* Wall., plants which are abundant in the volcanic regions of Java (*A. J. P.*, 1879); while Bourquelot (*C. R. S. B.*, iii, 1896) detected it in *Monotropa Hypopitys* Walt., in *Polygala Senega* L., and in other species of Polygala. (See also *A. J. P.*, 1898, 412.) Much of the so-called oil of wintergreen is obtained from the sweet birch, *Betula lenta* L., which yields a product physically and chemically indistinguishable from methyl salicylate. It is mostly distilled in rather crude receptacles in those parts where the plants are abundant, as the mountains of North Carolina and Tennessee. For description of these stills see *U. S. D.*, 20th ed., p. 764.

Occasionally the oil is very highly colored, and the wholesale dealers have three ways of "cleaning" it—redistillation, filtration, and decolorization. In the last method the oil to be decolorized is put into a bottle, crystals of citric acid are added, and the whole is allowed to stand, agitating occasionally, until the oil is colorless, or nearly so.

Oil of gaultheria when freshly redistilled is nearly colorless, but as found in commerce has a brownish-yellow or reddish color.

"Colorless or nearly colorless. Strong, characteristic odor; taste pungent. Specific gravity 1.180 to 1.187; *optical rotation* at 25° C. 0° to −1°; *refractive index* 1.537 to 1.539. Soluble in 6 parts of *alcohol* (70 per cent.) at 25° C. Contains not less than 99 per cent. of esters, calculated as methyl salicylate, $CH_3C_7H_5O_3$." *Br.*

Cahours found in addition to methyl salicylate a peculiar hydrocarbon, which he called *gaultherilene.* Trimble and Schroeter (*A. J. P.*, 1889, 398) found that the amount of the hydrocarbon *gaultherilene* was about 0.3 per cent. By analysis and vapor density determination they fixed its formula as $C_{15}H_{24}$, but they state that it may consist of a solid and a liquid portion. Power and Kleber (*Fritzsche Bros. Circ.*, No. 7) assert that this hydrocarbon belongs to the paraffin series, and state that it is probably triacontane, $C_{30}H_{62}$. They also find in the oil an aldehyde or ketone, with an odor like enanthic aldehyde, an apparently secondary alcohol, $C_6H_{16}O$, and an ester, $C_{14}H_{24}O_2$. To the alcohol and the ester are attributed the characteristic odor of the oil. True oil of gaultheria contains about 99 per cent. of methyl salicylate. (For methods of distinguishing the natural from synthetic oil see under *Methylis Salicylas.*)

Uses.—The therapeutic properties of this oil are precisely the same as those of methyl salicylate.

Dose, ten to twenty minims (0.6–1.3 cc.).

OLEUM GOSSYPII SEMINIS. U. S.

COTTONSEED OIL Ol. Gossyp. Sem. [Cotton Seed Oil]

"A fixed oil obtained from the seeds of cultivated varieties of *Gossypium herbaceum* Linné, or of other species of *Gossypium* (Fam. *Malvaceæ*)." *U. S.*

Oleum Gossypii; Cotton Oil; Huile de Semences de cotonnier, *Fr.*; Baumwollsamenöl, Baumöl, *G.*

This oil is produced in large quantities by the expression of cotton seed either hot or cold. The annual production amounts to upwards of 230,000,000 gallons. The residue left after the expression of the oil is known as *oil-cake* and is largely used as a food for cattle; the latter sometimes produces toxic effects which is due to the presence of a plant pigment of the phenol group called *gossypol* (see Carruth, *J. Am. Chem. S.*, 1918, xl, p. 647, and Alsberg and Schwartze, *J. P. Ex. T.*, 1921, xvii, p. 344). For a description of the process of extraction, see *A. J. P.*, 1896, 42; also 1898, 497.

This oil is obtained by expression from the seeds previously deprived of their shells. In this state they yield two gallons of oil to the bushel. As first obtained, it is thick and turbid, but it deposits a portion of its impurities on standing.

Besides this crude oil, there are three varieties in commerce, more or less purified, recognized as the *clarified,* the *refined,* and the *winter bleached.* The last mentioned corresponds to the official requirements.

The oil is clarified by first boiling it with water, to separate the mucilage, and then heating it with a weak solution of sodium hydroxide, which combines with the coloring matter and saponifies a part of the oil. The mixture becomes filled with black flecks, which deposit on standing and leave the oil but slightly colored. The loss in refining is usually from 4 to 7½ per cent., but occasionally amounts to 12 or 15.

Among the improvements in the purification of cottonseed oil are the processes of Chisholm using silicate of soda for clarifying and of Baskerville using a paper pulp or cellulose fiber.

The oil is used in the preparations of woollen cloth and morocco leather, and for oiling machinery. It has been found to be an excellent substitute for almond and olive oils in most pharmaceutical preparations in which they are employed, but it does not answer so well in the formation of lead plaster. Citrine ointment carefully prepared with it, too great heat being avoided, retains a rich orange color and proper unctuous consistence.

Cotton-seed oil belongs among the semi-drying group.

Description and Physical Properties.—"A pale yellow, oily liquid. It is odorless or nearly odorless, and has a bland taste. Cottonseed Oil is slightly soluble in alcohol, but is miscible with ether, chloroform, petroleum benzin, and with carbon disulphide.

"Specific gravity: 0.915 to 0.921 at 25° C. At a temperature below 12° C. particles of solid fat separate from the Oil, and at about 0° to –5° C. it becomes solid or nearly so. Dilute Cottonseed Oil with an equal volume of carbon disulphide, and add sulphuric acid (specific gravity 1.6 to 1.7): a reddish-brown color is rapidly produced. Mix 2 cc. of the Oil in a test tube with 2 cc. of a mixture of equal volumes of amyl alcohol and a 1 per cent. solution of precipitated sulphur in carbon di-sulphide, and immerse the test tube to one-third of its depth in a boiling, saturated aqueous solution of sodium chloride: a red color develops in from ten to fifteen minutes. Saponification value: not less than 190 and not more than 198. Iodine value: not less than 105 and not more than 114.

"Preserve in well-closed containers." *U. S.*

As this oil has been much used for adulterating olive oil, tests to distinguish it are very desirable. The test most depended upon is that known as *Halphen's test,* a mixed solution of amyl alcohol and carbon disulphide containing 1 per cent. of dissolved sulphur. This is given in the official test. It is stated that cotton seed oil, which has been heated to 250° C. no longer gives many of the characteristic reactions for detecting the oil.

Cottonseed oil possesses the nutritive and emollient properties of the fixed oils. Its value for some purposes is lessened by its flavor and its tendency to become gummy on exposure to the air.

Dose, two to six fluidrachms (7.5–22.5 cc.).

Off. Prep.—Linimentum Camphoræ, *U. S.;* Linimentum Ammoniæ, *N. F.*

OLEUM GRAMINIS CITRATI. Br.

OIL OF LEMON GRASS

"Oil of Lemon Grass is the oil distilled from Cymbopogon citratus, *Stapf,* and Cymbopogon flexuosus, *Stapf.*" *Br.*

Lemon-grass Oil; Malabar- or Cochin-grass Oil.

Both of these grasses are awnless and indigenous to India. *Cymbopogon citratus* is the genuine *Lemon grass* while *Cymbopogon flexuosus,* also called *Lemon grass,* is more properly designated *Malabar-* or *Cochin-grass.* The latter is claimed to yield the oil of best quality.

The *East Indian Lemon Grass Oil* comes from Malabar, Cochin, India and the Malay Peninsula. A product of the *C. citratus* comes from Ceylon, Burma and adjacent countries, as well as from Java, West Africa, Tonkin, Brazil and the West Indies.

It is officially described in the British Pharmacopœia, 1914, as "Dark yellow. Odor resembling that of verbena. Specific gravity 0.880 to 0.905; *optical rotation* –3° to +3°. Contains not less than 70 per cent. of aldehydes as determined by the process described under 'Oleum Cinnamomi.'" *Br.*

The chief aldehyde present is citral, of which it contains 70 to 85 per cent. Linalool, geraniol and methyl heptenone are also reported present in small amounts. The principal use of the oil is as a source for manufacturing ionone and in perfuming cheap soaps. (See also *Oil of Citronella,* Part II.)

Oil of lemon grass is sometimes used in Eastern countries as a carminative and stimulant in *doses* of one-half to three minims (0.03–0.2 cc.).

OLEUM JUNIPERI. U. S., Br.

OIL OF JUNIPER Ol. Junip. [Juniper Oil]

"The volatile oil distilled from the ripe fruit of *Juniperus communis,* Linné (Fam. *Pinaceæ*)." *U. S.* "Oil of Juniper is the oil distilled from the ripe fruit of Juniperus communis, *Linn.,* and rectified." *Br.*

Oleum Fructus (vel Baccæ) Juniperi; Oil of Juniper Berries; Huile volatile (Essence) de Genièvre, *Fr.;* Oleum Juniperi, *P. G.;* Wachholderöl, Wachholderbeeröl, *G.;* Essenza di ginepro, *It.*

The proportion of oil which juniper berries afford is variously given as from 0.3 to 2.3 per cent.; the usual yield is probably about 1 per cent.

Description and Physical Properties.—"A colorless or faintly green or yellow liquid, having the characteristic odor and taste of juniper berries.

"The Oil is soluble in 4 volumes of alcohol, with not more than a slight cloudiness. Specific gravity: 0.854 to 0.879 at 25° C. Optical rotation: varies from 0° to –15° in a 100 mm. tube at 25° C. Refractive index: 1.4790 to 1.4840 at 20° C. A solution of the recently distilled Oil in alcohol (1 in 4) is neutral or only slightly acid to moistened litmus paper. The Oil meets the requirements of the test for *heavy metals in volatile oils.*

"Preserve in well-stoppered, completely filled, amber-colored bottles, in a cool place, protected from light." *U. S.*

"Colorless or pale yellowish-green. Odor that of the fruit; taste warm, aromatic and bitter. Specific gravity 0.862 to 0.890, increasing with age; *optical rotation* –3° to –15°; *refractive index* at 25° C. 1.472 to 1.488. Soluble, when freshly distilled, in 4 parts of a mixture of equal volumes of *alcohol* (90 per cent.) and *absolute alcohol,* becoming less soluble with age." *Br.*

Oil of Juniper consists chiefly of pinene and cadinene. Its characteristic aroma, however, is due to small quantities of some unknown ingredient. It was at one time believed that this was an ester, but this cannot be the case as the odor persists after the complete saponification of the small amount of ester. On cooling the oil deposits a crystalline substance known as *juniper camphor;* this has a melting point of 165° to

166° C. Oil of turpentine is often fraudulently added, but may be detected by the specific gravity of the mixture being less than that of the unadulterated oil of juniper.

Uses.—In its medicinal properties oil of juniper apparently resembles the oil of turpentine. It is chiefly used for its stimulant action in chronic disorders of the genito-urinary tract. It is sometimes employed as a diuretic in certain forms of *dropsy* especially in conjunction with other drugs. On account, however, of its local irritant action, it may exercise injurious effects upon the kidneys, especially when these organs are inflamed. Its widespread use as an ingredient of patent medicines intended for disorders of the kidney is greatly to be deprecated. It is frequently combined with potassium bitartrate.

Dose, one to five minims (0.06–0.3 cc.).

Off. Prep.—Spiritus Juniperi, *Br.;* Acetum Aromaticum, *N. F.*

OLEUM LAVANDULÆ. U. S., Br.

OIL OF LAVENDER Ol. Lavand.

" The volatile oil distilled from the fresh flowering tops of *Lavandula Spica* Linné (*Lavandula officinalis* Chaix, *Lavandula vera* DeCandolle) (Fam. *Labiatæ*). Oil of Lavender yields not less than 30 per cent. of esters calculated as linalyl acetate $[C_{10}H_{17}.C_2H_3O_2]$." *U. S.* " The oil distilled from the flowers of Lavandula vera, *DC.*" *Br.*

Oleum Lavandulæ Florum, *U. S. VIII;* Oil of Lavender Flowers; Huile volatile de Lavande officinale, *Fr. Cod.;* Essence de Lavande, *Fr.;* Oleum Lavandulæ, *P. G.;* Lavandelöl, *G.;* Essenza di lavanda, *It.;* Esencia de espliego, *Sp.*

This oil is usually distilled from the flowers (see *Lavender Flowers,* Part II) and flower stems conjointly, though of finer quality when obtained from the former exclusively. Dried lavender flowers are said to yield from 1 to 1.5 per cent. of oil According to Zeller, the fresh flowers yield 1.03, the dried 4.3, the whole fresh herb in flower 0.76 per cent. It is said that the portion of oil first distilled is most fragrant, and is often kept separate, and sold at a higher price.

Description and Physical Properties.—" A colorless or yellow liquid, having the characteristic odor and taste of lavender flowers.

" The Oil is soluble in 3 volumes of 70 per cent. alcohol, by volume. Specific gravity: 0.875 to 0.888 at 25° C. Optical rotation: varies from –3° to –10° in a 100 mm. tube at 25° C. Refractive index: 1.4600 to 1.4640 at 20° C. Shake 5 cc. of Oil of Lavender with an equal volume of distilled water in a narrow, graduated, 10 cc. glass-stoppered cylinder: the volume of the Oil does not diminish (*alcohol*). Shake 20 cc. of the Oil with 40 cc. of 5 per cent. alcohol in a 100 cc. glass-stoppered cylinder. When the mixture has cleared, withdraw 30 cc. of the alcoholic solution, by means of a pipette, and place it in a 125 cc. Erlenmeyer flask. Neutralize the solution with half-normal potassium hydroxide, using 2 drops of phenolphthalein T.S. as indicator, add 5 cc. of half-normal potassium hydroxide, and heat the mixture on a bath of boiling water under a reflux condenser during one hour. Allow the mixture to cool, remove the flask from the bath, and titrate the excess of alkali with half-normal hydrochloric acid: not less than 4.7 cc. is required for neutralization (*acetins*).

" Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

" Pale yellow or yellowish-green. Odor that of the flowers; taste pungent, slightly bitter. Specific gravity 0.883 to 0.900; *optical rotation* –3° to –10°. Soluble in 4 parts of *alcohol* (70 per cent.). Contains from 7 to 11 per cent. of *esters* (Engish oil), or not less than 30 per cent. of *esters* (foreign oil), calculated as linalyl acetate, $C_{10}H_{17}C_2H_3O_2$." *Br.*

The principal constituent is linalool. It also contains linalyl acetate (from 30 to 45 per cent. in the oil from French flowers, and from 7 to 10 per cent. in the oil from English flowers), the butyric ester of the same alcohol, geraniol, a very small amount of cineol (more in the English than in the French oil), and sometimes traces of pinene, limonene, and a sesquiterpene.

Oil of Spike is procured from the broad-leaved variety of lavender which grows wild in Europe, the *Lavandula Spica* of De Cavanilles. Its odor is less fragrant than that of common oil of lavender, and is somewhat analogous to that of oil of turpentine, with which it is said to be often adulterated. It is used by artists in the preparation of varnishes. The oil of spike contains about 30 per cent. of cineol and but small quantities of esters.

Oil of lavender is used chiefly as a perfume, though possessed of carminative and stimulant properties, and sometimes useful in cases of *nervous languor* and *headache.*

Dose, from one to five minims (0.06–0.3 cc.).

Off. Prep.—Spiritus Lavandulæ, *U. S., Br.;* Tinctura Lavandulæ Composita, *U. S., Br.;* Acetum Aromaticum, *N. F.;* Spiritus Odoratus, *N. F.;* Mistura Oleo-balsamica, *N. F.*

OLEUM LIMONIS. U. S., Br.

OIL OF LEMON Ol. Lemon. [Lemon Oil]

" The volatile oil obtained by expression from the fresh peel of the fruit of *Citrus Medica* var. *Limonum* (Risso) Hooker filius (Fam. *Rutaceæ*). Oil of Lemon yields not less than 4 per cent. of the aldehydes of Oil of Lemon calculated as citral $[C_{10}H_{16}O]$. Oil of Lemon having a terebinthinate odor must not be dispensed." *U. S.* " Oil of Lemon is the oil obtained from Lemon Peel by various methods of expression." *Br.*

Oleum Limonum; Huile volatile de Citron, *Fr. Cod.;* Essence de Citron, *Fr.;* Oleum Citri, *P. G.;* Citronenöl, *G.;* Olio de limone, *It.;* Esencia de limon, *Sp.*

The exterior rind of the lemon abounds in a volatile oil, which, being contained in distinct cells, may be separated by simple expression. The rind is first grated from the fruit, and then submitted to pressure in a bag of fine cloth. The oil thus obtained is allowed to stand till it becomes clear, when it is decanted, and kept in stoppered bottles. By a similar process, the oil called by the French *huile de cédrat* is procured from the citron. These oils may also be obtained by distillation, but thus procured, though clearer, and, in consequence of the absence of mucilage, less liable to change on keeping, they have less of the peculiar flavor of the fruit, and the mode by expression is generally preferred. A third method of separating the oil, used in Calabria and Sicily, is to put the grated rind into hot water and skim off the oil as it rises to the surface. (*A. J. P.*, 1868, p. 27.) The method employed to obtain the finest oil is, however, that known as the écuelle process. The écuelle is an instrument usually made of tinned copper, bowl-shaped, and armed with concentric rows of short spikes. Attached to the bottom of the bowl is a hollow handle, closed at the bottom. This acts as a reservoir for the oil as the fruit is rubbed by the workmen over the sharp teeth. The oils are brought from Italy, Portugal, or Southern France.

The oils of lemons and oranges, as well as those of the other *Aurantiaceæ,* will keep indefinitely upon admixture with a small proportion of alcohol (one ounce to a pound of the oil). When wanted for use, a quantity of water equal to that of alcohol, added to the mixture, will unite with the alcohol, and subside, leaving the oil free of the alcohol for all practical purposes. The best method of preservation is to add 10 per cent. of a bland fixed oil such as olive or cottonseed, which must subsequently be allowed for in measuring the oil for use.

Description and Physical Properties.—" A pale yellow or greenish-yellow liquid, having the characteristic odor and taste of the outer part of fresh lemon peel.

" The Oil is soluble in 3 volumes of alcohol, and in all proportions in dehydrated alcohol, carbon disulphide, and in glacial acetic acid. Specific gravity: 0.851 to 0.855 at 25° C. Optical rotation: varies from +57° to +64° in a 100 mm. tube at 25° C. Refractive index: 1.4744 to 1.4755 at 20° C. A solution of the recently expressed Oil in alcohol (1 in 3) is neutral or only slightly acid to moistened litmus paper. Oil of Lemon when distilled as described under *Oleum Aurantii,* gives the following results: The angle of rotation of the first 5 cc. is not more than 5 degrees less than that of the original Oil. The refractive index of this same portion is not less than 0.0020 and not more than 0.0027 lower than that of the original Oil.

" Preserve in completely filled, well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

" Pale yellow. Volatile; odor that of lemons; taste warm, afterwards slightly bitter. Specific gravity 0.857 to 0.860: *optical rotation* + 58° to + 64°; *refractive index* at 25° C. 1.473 to 1.476. Contains not less than 4 per cent. by weight of aldehydes, calculated as citral, $C_{10}H_{16}O$, as determined by the following process." *Br.*

Assay.—" Place about 15 cc. of Oil of Lemon in a tared, 250 cc. Erlenmeyer flask, and weigh accurately. Add 10 cc. of an alcoholic solution of phenylhydrazine (1 in 10) (not darker in color than pale yellow), and allow it to stand for thirty minutes at room temperature. Then add 3 drops of methyl-orange T.S., and neutralize the liquid by the addition of half-normal hydrochloric acid. If difficulty is experienced in determining the end point of the reaction, continue the titration until the liquid is distinctly acid, transfer it to a separatory funnel, and after the layers have separated draw off the alcoholic portion. Wash the oil remaining in the funnel with distilled water, adding the washings to the alcoholic solution, and titrate the latter with half-normal sodium hydroxide. Carry out a blank test identical with the foregoing, omitting the Oil of Lemon, and note the amount of half-normal hydrochloric acid consumed. Subtract the number of cc. of half-normal sodium hydroxide from the number of cc. of half-normal hydrochloric acid consumed in the test containing the Oil of Lemon, and this result from the number of cc. of half-normal hydrochloric acid consumed in the test without the Oil of Lemon. Each cc. of this difference corresponds to 0.07609 Gm. of aldehydes calculated as citral." *U. S.*

" To 20 grammes of the Oil contained in a flask add 20 millilitres of *N/2 solution of hydroxylamine hydrochloride,* 8 millilitres of *N/1 alcoholic solution of potassium hydroxide* and 20 millilitres of *alcohol* (90 per cent.). Attach a reflux condenser, boil for thirty minutes, cool, and dilute with 250 millilitres of *water,* rinsing the condensing tube into the flask with part of this quantity. Neutralise the solution thus obtained with *N/1 alcoholic solution of potassium hydroxide, solution of phenolphthalein* being used as indicator, and then titrate with *N/2 solution of sulphuric acid, solution of methyl orange* being used as indicator. Repeat the experiment, omitting the Oil of Lemon. The quantity of *N/2 solution of sulphuric acid* required in the second experiment exceeds that required in the first experiment by not less than 10.5 millilitres (presence of not less than 4 per cent. of aldehydes, calculated as citral, $C_{10}H_{16}O$)." *Br.*

Constituents.—Oil of lemon consists chiefly of dextrogyrate limonene, which, together with phellandrene, makes up nearly 90 per cent. of the oil. Its pleasant aroma is due to the presence of about 7 or 8 per cent. of the aldehyde citral and a small amount of citronellal, $C_{10}H_{18}O$. Pinene, higher aldehydes, as octyl and nonyl, terpineol, octylene, camphene, methyl heptenone, citronellal, linalyl acetate, bisabolene, cadinene, methyl anthranilate and geranyl acetate have also been reported in small amounts.

Also a lemon-camphor, *citraptene*, which appears to be *dimethoxy coumarin*, is present to the extent of 2 per cent. This constituent has been found to be identical with *limettin*. Of these the citral is the constituent to which the oil chiefly owes its aroma and value. Umney and Swinton (*P. J.*, 1898, 196) state that citral, citronellal, and an ester of geraniol are all necessary to form the true odor of oil of lemon. Citral boils under normal atmospheric pressure at from 228° to 229° C. without decomposition if pure, and, like aldehydes, forms stable compounds with alkaline bisulphites. Schimmel & Co. now prepare the citral in a pure state, and recommend its use for enriching the ordinary oil of lemon.

For use in perfumery there have been placed on the market oils of lemon from which the terpenes have been removed. Parry (*Ch. & Dr.*, 1913, p. 378) discusses at some length the relative advantages of terpeneless and sesquiterpeneless oils and normal oils. The ordinary terpeneless oils contain from 42 to 45 per cent. of citral, while those that are sold as sesquiterpeneless contain from 65 to 72 per cent. citral. He states that the latter products lack the sweetness and softness of odor of those containing less citral, the overpowering odor of the latter constituent destroying the balance of harmony in the odor of the oil. He states that users of these products claim to get the best results from oils containing slightly less than 40 per cent. of citral and from which the whole of the terpenes have not been removed. The characters of the commercial terpeneless oils are as follows: sp. gr. at 15° C., 0.8935 to 0.899; optical rotation, $-5°$ to $-8° 30'$; refractive index, 1.4810; citral, 42 to 48 per cent. The sesquiterpeneless oils are slightly higher in specific gravity, lower in optical rotation and always run above 65 per cent. of citral.

Oil of lemon is often adulterated by the fixed oils and by alcohol, and sometimes with purified oil of turpentine, which is difficult of detection, from its similar composition and specific gravity, except with the polariscope. One of the tests for the presence of this oil is the terebinthinate odor produced when the adulterated oil is evaporated from heated paper; the official quantitative test defining the percentage of citral will be of service in detecting these adulterations. The most insidious adulteration of oil of lemon is the use of *citrene*, the terpene left after the extraction of citral from oil of lemon which has been used in making terpeneless oil.

Parry (*Schim. Rep.*, Apr., 1912, p. 78) reports several shipments of lemon oil which upon investigation were found to be adulterated with Greek turpentine oil. They were noted by their low optical rotation, $+50°$ to $+54°$, and their low citral content, 3.3 to 4.1 per cent.

In consequence of some seizures of lemon oil alleged to be adulterated with turpentine, in 1906, a number of importers stated their belief that pinene was normally present in appreciable amounts in some lemon oils. In consequence of this the U. S. Dept. of Agriculture undertook a special investigation of the subject, sending a trained observer and analyst to the producing countries, and published the results of the investigation in a special bulletin called "Circular 46, by E. M. Chace." The investigation showed conclusively that lemon oil shows no appreciable amount of pinene.

Spirit of Lemon (*Spiritus Limonis, U. S.* 1890) was made by dissolving 50 cc. of oil of lemon in 900 cc. of deodorized alcohol, to which 50 Gm. of freshly grated lemon peel were added, the whole macerated for twenty-four hours, filtered, and enough deodorized alcohol added through the filter to make the whole measure 1000 cc.

Uses.—The oil of lemon is much less active than most of the other official volatile oils, and is used almost exclusively for its flavoring properties.

Dose, two to five minims (0.12–0.3 cc.).

Off. Prep.—Elixir Aromaticum (from Spirit), *U. S.;* Spiritus Aurantii Compositus, *U. S.;* Acetum Aromaticum, *N. F.;* Spiritus Odoratus, *N. F.;* Mistura Oleo-balsamica, *N. F.*

OLEUM LINI. U. S., Br.

LINSEED OIL. Ol. Lini. [Oil of Flaxseed, Raw Linseed Oil]

"A fixed oil obtained from Linseed. Linseed Oil which has been 'boiled' must not be used nor dispensed." *U. S.* "Linseed Oil is the oil expressed from Linseed." *Br.*

Huile de Semence de Lin, *Fr.;* Oleum Lini, *P. G.;* Leinöl, Leinsamenöl, *G.;* Olio di lino, *It.;* Aceite de linaza, *Sp.*

This oil is obtained by expression from the seeds of *Linum usitatissimum*, or common flax, which contain from 30 to 40 per cent. In its preparation for commerce, the seeds are usually roasted before being pressed, in order to destroy the gummy matter contained in their coating, and expressed hot. The oil is thus obtained more free from mucilage, but more highly colored and acrid than when procured by cold expression. For medicinal use, therefore, it should be prepared without heat, and, as it is apt to become rancid quickly on exposure, it should be used as soon after expression as possible. It is said to be obtained purer and in larger proportion by treating the crushed seeds with carbon disulphide than by expression.

Description and Physical Properties.—"A yellow, oily liquid, having a peculiar odor, and a bland taste. When exposed to the air, it gradually thickens, darkens in color, and acquires a more pronounced odor and taste. Linseed Oil is slightly soluble in alcohol, but is miscible with ether, chloroform, petroleum benzin, carbon disulphide, and with oil of turpentine.

"Specific gravity: 0.925 to 0.935 at 25° C. Linseed Oil, when spread in a thin layer on a glass plate and allowed to stand in a warm place, is gradually converted into a hard, transparent film (*non-drying oils*). Dissolve 2 Gm. of Linseed Oil in 20 cc. of a mixture of equal volumes of alcohol and ether, which has previously been neutralized with tenth-normal sodium hydroxide, using 5 drops of phenolphthalein T.S. as indicator, and titrate with tenth-normal sodium hydroxide to the production of a pink color, which persists for fifteen seconds: not more than 1.5 cc. of tenth-normal sodium hydroxide is required (*free acid*). To 10 cc. of the Oil, add 3 Gm. of potassium hydroxide, 10 cc. of alcohol and 10 cc. of distilled water, and heat the mixture on a water bath with frequent agitation until a clear solution results: the addition of 100 cc. of distilled water to this solution yields a clear liquid, free from oily drops (*mineral* or *rosin oils*). Warm 2 cc. of the Oil with an equal volume of glacial acetic acid in a test tube, agitating frequently, and after cooling add to the mixture 1 drop of sulphuric acid: a greenish color is produced (a violet color under these circumstances indicates the presence of *rosin* or *rosin oils*). Unsaponifiable matter: not more than 1.5 per cent. Saponification value: not less than 187 and not more than 195. Iodine value: not less than 170.

"Preserve in well-stoppered containers." *U. S.*

"Yellowish-brown. Characteristic odor; taste bland. Specific gravity 0.930 to 0.940; *saponification value* 187 to 195; *iodine value* not less than 170; *acid value* not more than 3.0; *unsaponifiable matter* not more than 1.0 per cent.; *refractive index* at 40° C. 1.4725 to 1.4748. Does not congeal at temperatures higher than $-20°$ C. Gradually thickens on exposure to the air, forming, when spread in thin layers, a hard transparent varnish. A mixture of 2 millilitres of the Oil with an equal volume of *acetic anhydride,* warmed and shaken, and then cooled to 15.5° C., is not colored violet by the addition of 2 drops of a cooled mixture of 2 parts by weight of *sulphuric acid* and 1 part by weight of *water* (absence of resin and resin oils)." *Br.*

It has the property of drying or becoming solid on exposure to the air, acquiring during the process a strong odor and taste, and increasing as much as 12 per cent. of its weight, owing to the formation of *linoxyn* by atmospheric oxidation. The drying property resides in a constituent which, to distinguish it from the olein of the non-drying oils, is named *linolein,* and is the glyceride of *linoleic acid.* Linseed oil contains about 10 to 15 per cent. of glycerides of solid fatty acids, palmitic, myristic, and stearic, and 85 to 90 per cent. of liquid glycerides. Hazura (*J. Soc. Chem. Ind.,* 1888, 506) states that the liquid fatty acids consist of about 5 per cent. of oleic acid, $C_{18}H_{34}O_2$, 15 per cent. of *linoleic acid,* $C_{18}H_{32}O_2$, 65 per cent. of *isolinolenic acid,* $C_{18}H_{30}O_2$, and 15 per cent. of *linolenic acid,* $C_{18}H_{30}O_2$. Boiled with litharge, red lead, manganese dioxide, and other so-called "driers," it absorbs oxygen still more rapidly, and gains 14 per cent. in weight. Its acridity is owing to the presence of a small portion of an acrid oleoresin. From its drying property, it is useful in painting and in making printers' ink and in linoleum and oil cloth manufacture. The chief adulteration of linseed oil is with mineral oils and rosin oil. For their detection, see official tests already given.

The prohibition of the use of boiled linseed oil for medicinal purposes has its origin in the fact that much of the boiled linseed oil of commerce contains a compound of lead or manganese as a drying agent. Instances are on record where lead-containing boiled linseed oils caused the death of cattle to which the oil had been administered.

Uses.—The oil is laxative in the dose of a fluidounce (30 cc.), but, on account of its disagreeable taste, is seldom given internally. It has, however, been highly recommended as a cure for *piles,* in the dose of two fluidounces (60 cc.) of the fresh oil, morning and evening. It is sometimes added to purgative enemata. Particular care must be observed not to use boiled linseed oil for any medicinal purposes, as the latter frequently contains compounds of lead which give it poisonous properties.

Dose, one to two fluidounces (30–60 cc.).

OLEUM MENTHÆ PIPERITÆ. U. S., Br.

OIL OF PEPPERMINT Ol. Menth. Pip. [Peppermint Oil]

"The volatile oil distilled from the fresh, over-ground parts of the flowering plant of *Mentha piperita* Linné (Fam. *Labiatæ*), rectified by steam distillation. Oil of Peppermint yields not less than 5 per cent. of esters, calculated as menthyl acetate [$C_{10}H_{19}.C_2H_3O_2$], and not less than 50 per cent. of total menthol [$C_{10}H_{19}.OH$], free and as esters." *U. S.* "Oil of Peppermint is the oil distilled from fresh flowering peppermint, Mentha piperita, *Sm.,* and rectified, if necessary." *Br.*

Huile volatile de Menthe poivrée, *Fr. Cod.;* **Essence de Menthe poivrée,** *Fr.;* **Oleum Menthæ piperitæ,** *P. G.;* **Pfefferminzöl,** *G.;* **Essenza di menta,** *It.;* **Escencia de menta piperita,** *Sp.*

For account of the peppermint plant and its cultivation see *Mentha Piperita.*

Peppermint varies considerably in the quantity of oil which it affords. Zeller gives as the product of the fresh herb, from 0.37 to 0.68 per cent., of the dried 1.14 per cent. The yield is generally less than 1 per cent. This oil is largely distilled in the States of Michigan, Indiana, and New York, Michigan producing the largest quantity. The oil is also largely produced in Japan. (See illustrated paper, *C. D.,* 1896, 601.)

Description and Physical Properties.—"A colorless liquid, having a strong, penetrating odor of peppermint, and a pungent taste, followed by a sensation of cold when air is drawn into the mouth.

"The Oil is soluble in 4 volumes of 70 per cent. alcohol, by volume, showing not more than a slight opalescence and no separation of oil globules (*dementholized or impure peppermint oil*). Specific gravity: 0.896 to 0.908 at 25° C. Optical rotation: varies between −23° and −33° in a 100 mm. tube at 25° C. Refractive index: 1.4600 to 1.4710 at 20° C. A solution of the recently rectified Oil in 70 per cent. alcohol (1 in 4) is neutral to moistened litmus paper. Distil 1 cc. from 25 cc. of Oil of Peppermint, and carefully superimpose the distillate on 5 cc. of mercuric chloride T.S. in a test tube: a white film does not form at the zone of contact within one minute (*dimethyl sulphide found in non-rectified peppermint oils*).

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

"Colorless, pale yellow, or greenish-yellow. Odor that of peppermint herb; taste pungent and aromatic followed by a sensation of cold. Specific gravity 0.900 to 0.920; *optical rotation* −20° to −35°. Soluble in 4 parts of *alcohol* (70 per cent.). Contains not less than 50 per cent. of total *alcohols*, free and combined, calculated as menthol, $C_{10}H_{20}O$, and not less than 5 per cent. of esters, calculated as menthyl acetate, $C_{10}H_{19}O_2H_3O_2$." *Br.*

"**Assay for Esters.**—Place 10 cc. of Oil of Peppermint in a tared, 125 cc. Erlenmeyer flask, and weigh accurately. Add 25 cc. of half-normal alcoholic potassium hydroxide, connect the flask with a reflux condenser, and boil the mixture on a water-bath for one hour. Allow the mixture to cool, disconnect the flask from the condenser, and titrate the excess of alkali with half-normal sulphuric acid, using 10 drops of phenolphthalein T.S. as indicator. Subtract the number of cc. of half-normal sulphuric acid required for neutralization from the 25 cc. of half-normal alcoholic potassium hydroxide taken, multiply the difference by 9.912, and divide this product by the weight of Oil of Peppermint taken: the result shows the per cent. of esters calculated as menthyl acetate.

"**Assay for Total Menthol.**—Place 10 cc. of Oil of Peppermint in an acetylization flask of 100 cc. capacity, add 10 cc. of acetic anhydride and 1 Gm. of powdered anhydrous sodium acetate. Boil the mixture gently for one hour, cool, disconnect the flask from the condenser, transfer the mixture to a small separatory funnel, rinsing the acetylization flask with three successive 5 cc. portions of warm distilled water, and add the rinsings to the separatory funnel. When the liquids have completely separated, remove the aqueous layer, and wash the remaining oil with successive portions of sodium carbonate T.S., diluted with an equal volume of distilled water, until the mixture is alkaline to 2 drops of phenolphthalein T.S. Dry the resulting Oil with fused calcium chloride, and filter. Transfer 5 cc. of the dry acetylized oil to a tared, 100 cc. Erlenmeyer flask, note the exact weight, add 50 cc. of half-normal alcoholic potassium hydroxide, connect the flask with a reflux condenser, and boil the mixture on a water bath for one hour. Allow the mixture to cool, disconnect the flask from the condenser, and titrate the excess of alkali with half-normal sulphuric acid using 10 drops of phenolphthalein T.S. as indicator. Calculate the per cent. of menthol by the following formula:

$$\text{Per cent. of total menthol} = \frac{A \times 7.811}{B - (A \times 0.021)} \times [1 - (E \times 0.0021)]$$

"A is the result obtained by subtracting the number of cc. of half-normal sulphuric acid required in the above titration from the number of cc. of half-normal alcoholic potassium hydroxide originally taken, B is the weight of acetylized oil taken, and E is the per cent. of esters calculated as menthyl acetate." *U. S.*

Upon cooling or long standing it deposits a stearopten called *peppermint camphor* or *menthol*, $C_{10}H_{19}OH$. (See *Menthol.*) A complete summary of the composition of American peppermint oil, on the authority of Power and Kleber, given in *Schimmel & Co.'s Report* for April, 1897, shows the following constituents: acetaldehyde, isovaleraldehyde, dimethyl sulphide, amyl alcohol, isovaleric acid, pinene, phellandrene, cineol, limonene, *menthone*, $C_{10}H_{18}O$, menthol, the acetate and isovalerate of menthyl, *a-lactone*, $C_{10}H_{16}O_2$, and cadinene. Menthol, its oxidation product menthone, and the acetic and isovaleric esters of menthol have been identified as present in English and French peppermint oils, which probably also contain most of the other constituents mentioned above. Menthol and its esters are regarded as the main constituents of oil of peppermint and an official assay for determining the percentage of menthol will be found above. The dimethyl sulphide and some of the other constituents are objectionable from the flavoring standpoint, and are largely removed by the steam distillation which is required for rectification. The polariscope has been shown to be an uncertain guide in determining the quality of oil of peppermint. (A. B. Stevens, *Proc. A. Ph. A.*, 1888, p. 97.)

Power and Kleber first proposed (*Ph. Rund.*, 1894, 157) to estimate the menthol in oil of peppermint by acetylizing a sample and saponifying an exactly weighed portion of the acetylized oil after washing, drying, and filtering the same. Kebler (*A. J. P.*, 1897, 192) proposed to take instead a weighed quantity of the oil, acetylize it, and then saponify the product after washing and neutralizing it. In *Schimmel & Co.'s Report* for October, 1897, Kleber criticizes Kebler's modification, and claims greater accuracy for the original method. Of course, this determination gives the total menthol; a determination of the combined menthol is had by titrating with alcoholic alkali.

Peppermint oil has been variously mixed and adulterated with the following substances: alcohol, oil of turpentine, oil of copaiba, oil of erigeron (from the erigeron plant growing with the peppermint plant, and being collected with it for distillation), oil of eucalyptus, oil of pennyroyal, and others. Most of these are detectable by the official tests, or when present lower the assay strength, or are readily recognized by the odor or taste, which they communicate to the oil. For further details concerning some of these adulterants and their detection, see *U. S. D.*, 19th ed., p. 854, 855.

Uses.—Oil of peppermint possesses the physiological properties and therapeutic virtues of menthol, and may be used for practically all those conditions in which menthol is of service but is, proportionally, a more active local irritant. It is generally preferred for internal use because of its more pleasant taste. It is an excellent carminative and gastric stimulant, and is widely employed in *flatulence, nausea,* and *gastralgia.* It adds to a stimulating effect upon the alimentary canal an antiseptic and local anesthetic influence. Heinz (*Therap. Halbmonatsh.*, April 1, 1920) asserts that it is an active cholagogue and recommends its use in *gall-stones.* As a local application for *coryza* it may be used in strengths of from three to ten minims to an ounce of liquid petrolatum or olive oil. Incorporated into a lozenge it offers a pleasant and efficient antiseptic and anesthetic in *pharyngitis.* Internally it may be given either rubbed up with sugar and then dissolved in water, or more commonly in the form of the spirit. It is extremely popular as a flavoring agent.

Dose, one to five minims (0.06–0.3 cc.).

OLEUM MENTHÆ VIRIDIS. U. S., Br.

OIL OF SPEARMINT Ol. Menth. Vir. [Spearmint Oil]

"The volatile oil distilled from the fresh, overground parts of the flowering plant of *Mentha spicata* Linné (*Mentha viridis* Linné) (Fam. *Labiatæ*). Oil of Spearmint yields not less than 43 per cent. by volume, of carvone [$C_{10}H_{14}O$]." *U. S.* "Oil of Spearmint is the oil distilled from fresh flowering spearmint, Mentha viridis, *Linn.*, or Mentha crispa, *Roth.*" *Br.*

Huile volatile (Essence) de Menthe verte, *Fr.;* Römischminzöl, Krauseminzöl, *G.*

According to Lewis, ten pounds of spearmint yield an ounce of oil; by others the product is stated not to exceed one part from five hundred. The oil is largely distilled in this country, the whole plant being used. It is pale yellow or greenish when recently prepared, but becomes red with age, and ultimately almost of a mahogany color.

Description and Physical Properties.—"A colorless, yellow or greenish-yellow liquid, having the characteristic odor and taste of spearmint.

"The Oil is soluble in 1 volume of 80 per cent. alcohol, by volume, forming a clear solution, which becomes cloudy on dilution with more of the alcohol. Specific gravity: 0.917 to 0.934 at 25° C. Optical rotation: varies from $-38°$ to $-56°$ in a 100 mm. tube at 25° C. Refractive index: 1.4820 to 1.4900 at 20° C. A solution of the recently distilled Oil in an equal volume of 80 per cent. alcohol is neutral or only slightly acid to moistened litmus paper.

"**Assay.**—Proceed as directed under *Oleum Cari,* using 10 cc. of Oil of Spearmint. The oily layer measures not more than 5.7 cc., indicating the presence of not less than 43 per cent. by volume, of carvone.

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

"Colorless, pale yellow, or greenish-yellow, becoming darker on keeping. Odor and taste those of spearmint herb. Specific gravity 0.925 to 0.940; *optical rotation* $-30°$ to $-50°$. Soluble in 3 parts of *alcohol* (90 per cent.). Forms a clear solution with 1 part of a mixture of equal volumes of *alcohol* (90 per cent.) and *alcohol* (70 per cent.), the solution becoming turbid on further dilution." *Br.*

Oil of spearmint contains a terpene, l-limonene, $C_{10}H_{16}$, and l-carvone, $C_{10}H_{14}O$. Baeyer found the l-carvone in both German and American oils to the amount of from 35 to 56 per cent. (*A. Pharm.*, ccxii, 238.) Schimmel & Co., in an investigation of Russian oil, found from 5 to 10 per cent. of carvone only, but 50 to 60 per cent. of linalool, together with some cineol and l-limonene. (*Schim. Rep.*, April, 1898.) It is used chiefly for its flavor, especially in chewing gum.

The peculiar odor of spearmint oil has not yet been definitely associated with any of its constituents. It was for a time thought to be due to an acetic derivative of dihydrocuminyl, but this has recently been denied so far as the oil of American origin is concerned.

Dose, one to six minims (0.06–0.4 cc.).

Off. Prep.—Aqua Menthæ Viridis, *U. S. Br.;* Spiritus Menthæ Viridis, *U. S.*

OLEUM MORRHUÆ. U. S., Br.

COD LIVER OIL Ol. Morrh.

"The fixed oil obtained from the fresh livers of *Gadus morrhua* Linné and of other species of *Gadus.* Cod Liver Oil may be assayed for its vitamine A potency, and should then contain at least 50 units per Gm. Cod Liver Oil so assayed must be labeled 'This unit is not a measure of the antirachitic activity of Cod Liver Oil.'" *U. S.* "Codliver Oil is the oil expressed from the fresh liver of the cod, Gadus morrhua, *Linn.*, at a temperature not exceeding 85° C., and from which solid fat has been separated by filtration at about −5° C." *Br.*

Oleum Jecoris Aselli; Oleum Hepatis Morrhuæ; Cod Oil; Huile de Foie de Morue, *Fr. Cod.;* Huile de Morue, *Fr.;* Oleum Jecoris Aselli, *P. G.;* Leberthran, Stockfischleberthran, Dorschleberthran, Kablianleberthran, *G.;* Olio di fegato di merluzzo, *It.;* Aceite de higado de bacalao, *Sp.*

Gadus morrhua Linn.; *Morrhua vulgaris* Storer.—The *common cod* is between two and three feet long, with brown or yellowish spots on the back. The body is moderately elongated and somewhat compressed, and covered with soft, rather small scales, being quite conspicuous also on the head. Of the fins, which are soft, there are three on the back (dorsal), two anal, and a distinct caudal, and the fin (ventral) under the throat is narrow and pointed. The jaws are furnished with pointed irregular teeth, in several ranks. The gills are large, with seven rays. This species of cod inhabits the cold waters of the northern Atlantic, and is especially abundant on the Banks of Newfoundland, where it finds food adapted to its wants.

Besides the common cod, several other species of *Gadus,* frequenting the seas of northern Europe and America, contribute to furnish the cod liver oil of commerce. Among these De Jongh mentions *Gadus callariaus* L., or *dorsch* (*Morrhua americana* of Storer), *G. molva* L., or *ling, G. carbonarius* L., or *coal fish,* and *G. pollachius* L., or *pollack,* as affording the oil on the coast of Norway, where from 17,000,000 to 35,000,000 of codfish are annually taken. For an account of the mode of fishing for cod and of preparing the oil practised in Norway and Denmark, see *Ph. Ztg.,* 1900, 261; *Ph. Era,* 1904, 111; *C. D.,* 1904, 21.

Holmes (*J. Metab. R.,* 1922, ii, No. 1) has experimentally found that the oil obtained from the livers of the pollack, hake and haddock are equal in vitamin content to that from the true cod.

On the American coast, in addition to the pollack above mentioned, it is obtained also from the *hake* (*G. merluccius* L.) and the *haddock* (*G. æglefinus* L.). It is produced on our coast north of Boston. The oil is also largely produced in Newfoundland, Great Britain, Norway, and to some extent in Iceland.

The exact habits of the codfish still remain to be discovered. It is known that annually enormous schools or shoals of codfish visit the northern seas and are found along the coasts of Norway, Scotland, Iceland, Newfoundland and New England, Alaska, Japan and Siberia. The most noted fishing grounds are along the coast of Norway. In the vicinity of the Lofoten Islands the fish appear in February and remain for about two months. At Finmarken the fish do not appear until June and seem to be much less mature and are accompanied by other varieties of fish which are also caught by the fishermen for the sake of their livers. For this reason the Lofoten oil is of better quality than any other Norwegian oil. The codfishing industry originally had for its object the "cured" meat of the fish and the livers were at first thrown away with other putrescible and non-edible portions of the fish. From the empiric use of the oil which naturally exuded from the heaps of decomposing livers has risen an industry in which many thousands of barrels of the oil are produced annually, and from a small Norwegian district it has spread to all the countries bordering the Northern seas. The fish are usually caught by hook and line, rarely by nets or traps. The head of the fish is severed, the abdomen split and the liver removed by a deft twist of the operator's wrist.

Preparation.—In the early days of the industry the livers were allowed to accumulate in tanks or barrels and underwent a process of spontaneous decomposition in which the cells were ruptured and the oil exuded. The oil thus obtained was contaminated with basic decomposition products and possessed a disagreeable odor and a nauseating taste. Later the oil was obtained by steaming or by pressure and as sanitary conditions improved and scientific knowledge advanced the effort has been made to extract the oil from the livers while they are in as fresh a condition as possible. For this reason some of the former grades of cod liver oil such as the "raw" oil and "brown" oil are no longer seen or heard of. For a detailed description of the earlier methods of production and of the properties of the oil thus obtained see *U. S. D.,* 20th ed., p. 773.

The first high quality medicinal oil was obtained by treating the livers with steam to rupture the cell membranes, much in the same manner in which lard is "rendered." In the best equipped establishments the livers are "extracted" immediately after being taken from the fish, it having been found that exposure even if only for a few hours is very detrimental to the quality of the oil that is obtained. The livers are carefully sorted, all stained or abnormal livers being rejected. They are then placed in tin lined tanks provided with open steam coils and low pressure steam is blown through the mass which causes an immediate separation of oil. Patents have been obtained for the application of vacuum extraction methods or the extraction in an atmosphere of carbon dioxide but the steam extraction method just described is used in the majority of establishments.

The oil separated as described is filtered to separate cellular tissue fragments and is then bleached by treatment with fuller's earth or by exposure to sunlight. The oil thus prepared will congeal at low temperatures owing to the presence of stearin. In some establishments this is removed by chilling to −10° C. and expression, the separated stearin being sold for soap making, and the oil being called "non-congealing oil."

Some lower grades of oil are produced from livers which are unsuitable for the production of the high grade medicinal oil, and from livers which are mixed with other fish livers.

Cod liver oil prepared by the putrefactive method had a brown color and a strong offensive odor and flavor. It contained a large proportion of free fatty acids and of animal bases of the ptomaine type. The color of the modern oil is from the slightest tint of transparent yellow to a fine golden yellow. It is of a rather thin consistence, and has a characteristic odor and taste, by which it may be distinguished from other oils. When a decided odor of ordinary fish oil is perceived, the genuineness may always be suspected; it is quite distinct from that peculiar to the cod liver oil.

Description and Physical Properties.—"A pale yellow, thin, oily liquid. It has a peculiar, slightly fishy, but not a rancid odor, and a fishy taste.

"Cod Liver Oil is slightly soluble in alcohol, but is soluble in ether, chloroform, carbon disulphide, and in ethyl acetate.

"Specific gravity: 0.918 to 0.927 at 25° C. A solution of 1 drop of the Oil in 1 cc. of chloroform, when shaken with 1 drop of sulphuric acid, acquires a violet-red tint, gradually changing to reddish-brown. Dissolve 2 Gm. of Cod Liver Oil in 20 cc. of a mixture of equal volumes of alcohol and ether, which previously has been neutralized with tenth-normal sodium hydroxide, using 5 drops of phenolphthalein T.S. as indicator, and titrate with tenth-normal sodium hydroxide to the production of a pink color which persists for fifteen seconds: not more than 1 cc. of tenth-normal sodium hydroxide is required (*free acid*). Unsaponifiable matter: not more than 1.5 per cent. Saponification value: not less than 180 and not more than 190. Iodine value: not less than 140 and not more than 180.

"Preserve in a cool place, in well-closed containers which have been thoroughly dried before filling.

"**Assay.**—Proceed as directed under the vitamine A assay for *Cod Liver Oil.*" *U. S.* (See Part III.)

"Pale yellow. Slight, fishlike, but not rancid odor; taste bland, fishlike. Specific gravity 0.920 to 0.930; *saponification value* 179 to 192; *iodine value* 155 to 173; *acid value* not more than 2.5; *refractive index* at 40° C. 1.4704 to 1.4745; *unsaponifiable matter* not more than 1.5 per cent. When exposed for three hours to a temperature of 0° C., no solid fat separates." *Br.*

Composition.—The chemical composition of cod liver oil is very complicated. It consists in larger part of the glycerides of two unsaturated fatty acids, *jecoleic* ($C_{19}H_{36}O_2$) and *therapic* ($C_{17}H_{26}O_2$); smaller amounts of the glycerides of palmitic and stearic acids are present. But the so-called "stearin" separating from cod liver oil on cooling contains some unknown unsaturated compounds, as the cod liver stearin has a very high iodine value (113.4, Heyerdahl; 94, Lewkowitsch). The glycerides of the lower fatty acids, such as acetic, butyric, valeric, and capric acids, stated by various authors to occur in cod liver oil, are, according to Salkowski and Steenbuch, secondary products due to the putrefaction of the livers. The researches of Heyerdahl (*Cod Liver Oil and Chemistry,* P. Möller, London, 1895) give as present in the mixed fatty acids about 4 per cent. of palmitic acid, 20 per cent. of jecoleic acid, and 20 per cent. of therapic acid; *morrhuic acid,* $C_9H_{13}O_3N$, and *asellic acid,* $C_{17}H_{32}O_2$, have also been reported. Bull has stated (*B. Chem. G.,* 1906, xxxv, 70) that Heyerdahl's jecoleic acid does not exist, but that it is a mixture of *dihydroxystearic acid* and *dihydroxygadoleic acid.* Heyerdahl states that in the fresh state cod liver oil contains no hydroxy-acids.

A characteristic constituent of cod liver oil is *cholesterol,* which can be isolated by saponifying the oil and exhausting the soap with ether. The quantity of cholesterol, according to Allen and Thomson, is from 0.46 to 1.32 per cent. By reaction with ammonia in distillation the oil yields a volatile alkaloid, trimethylamine (see Part II), which has a strong pungent odor, recalling that of herring pickle, of which the same alkaloid is an ingredient. No other official fatty oil yields a similar product. (See *A. J. P.,* xxiv, 343.) Gautier has obtained from cod liver oil the leucomaines *butylamine, iso-amylamine, hexylamine,* and *dihydrolutidine,* and two fixed bases, *aselline,* $C_{25}H_{32}N_4$, and *morrhuine,* $C_{19}H_{27}N_3$. Aselline was found by its discoverer to be relatively feeble physiologically; morrhuine, of which about 2 milligrammes are believed to exist in a tablespoonful of ordinary cod liver oil, is affirmed to have the properties of exciting the appetite and acting as a powerful diuretic and diaphoretic. Besides these bases, an acid containing nitrogen has been found. This acid, *morrhuic acid,* $C_9H_{13}NO_3$, is probably identical with De Jongh's *gaduine. Gaduol* and *Morrhuol* are names which have been applied to the inspissated alcoholic extract of cod liver oil or of the alcoholic extraction of the livers themselves. It is described as a brown oily liquid, possessing a bitter, acrid taste. It was formerly claimed to possess the therapeutic virtues of cod liver oil and to contain iodine, bromine, phosphorus and alkaloids.

Some have been disposed to ascribe the virtues of cod liver oil to its iodine and bromine, but these are in too small proportion for any effect, and the oil has produced results which have never been obtained from iodine and bromine themselves. The presence of iodine cannot be detected by the usual tests. It is necessary to convert the oil into a soap and to carbonize this, before it will give evidence of iodine. The proportion never exceeds 0.05 per cent., or 1 part in 2000, and it is by no means certain that iodine is always, if ever, present in pure oil. The proportion of iodine present has been investigated by E. C. Stanford (*P. J.* [3], xiv, 353), who found it to be extremely minute, ranging from 0.00138 to 0.00433 per cent. with an average of 0.00322 per cent. The oil is capable of dissolving a larger proportion of iodine, and, if any specimen contain more than 0.05 per cent., there is reason to suspect that iodine has been added. Cod liver oil becomes rancid so easily that it contains varying amounts of free fatty acids, frequently showing their presence, even when freshly rendered. Medicinal oils, however, should not show more than from 0.3 to 0.7 per cent. of free acid, calculated as oleic acid.

The so-called active principles of cod liver oil which are found in the market under various names indicative of their origin are usually made by alcoholic extraction of the oil or of the livers themselves. They consist almost entirely of crude fatty acids, no iodine, bromine or phosphorus is detectable, the bases which are sometimes present are in very minute amount, and are probably of the ptomaine type, derived from partly decomposed products. These so-called alcoholic extracts or active principles are themselves scarcely soluble in diluted alcoholic menstrua, such as are used in preparing the so-called "tasteless" preparations of cod liver oil, so that such preparations can possess little or no activity due to cod liver products.

A preparation derived from cod liver oil, called *sodium morrhuate* has appeared in commerce. It is said to be prepared by the following method: Boil 100 Gm. of cod liver oil, 20 Gm. of sodium hydroxide (dissolved in the same volume of water), and 200 cc. of rectified spirit on a water bath under a reflux condenser for about four hours. The solution is then mixed with a little water, and exactly neutralized with dilute sulphuric acid. Some of the alcohol is then recovered and the solution mixed with nearly 200 Gm. of fairly large grained sand (washed with hydrochloric acid and water), and the whole quickly evaporated to dryness on the water bath. The dry residue is then extracted with ether in Soxhlet's apparatus (using ice water in the condenser), and the fatty acids liberated by a slight excess of the calculated quantity of dilute sulphuric acid (say, a diluted solution of nearly 18 cc. of strong sulphuric acid of sp. gr. 1.82). The fatty acids liberated are washed several times with water to free them from sulphuric acid, and then neutralized with an alcoholic solution of pure sodium hydroxide, using phenolphthalein as indicator. The neutral solution of sodium morrhuate is quickly evaporated to dryness at as low a temperature as possible. A three per cent. solution is used hypodermically and intravenously. Sodium morrhuate was suggested by Rogers (*B. M. J.*, 1919, i, 146) as a remedy for tuberculosis; it has since been tried with more or less success by a number of physicians, especially in India both in *tuberculosis* and in *leprosy* (see Davies, *Ind. Med. Gaz.*, 1921, lvi, 283).

Tests of Purity.—In consequence of the great demand for this oil, it has not infrequently been adulterated with other fixed oils, and occasionally others have been fraudulently substituted for it. The importance, therefore, of ascertaining some mode of testing its purity and genuineness is obvious.

There is reason to believe that all the oils from the livers of the *Gadidæ* have analogous properties. They have been indiscriminately used, and upon the results of their employment is based, in part, the present reputation of the medicine. They may, therefore, be considered as in fact one oil, so far as their medicinal use is concerned. Unfortunately, chemistry has yet discovered no perfectly reliable test. The furthest it has gone is to point out certain reactions which may be considered as evidences of the presence of biliary principles in the oil, thus indicating its hepatic origin. Among these probably the most characteristic is that of Hager and Salkowski, in which a drop of sulphuric acid, added to fresh cod liver oil, on a porcelain plate, causes a centrifugal movement in the oil, and gives rise to a fine violet color soon passing into a yellowish or brownish-red. Sometimes, instead of assuming the violet hue, the color immediately becomes a clear red or a dark brownish-red. This is said to be especially the case with those specimens of the oil which have been prepared by boiling the livers with water. Shark liver oil responds in like manner to the test of sulphuric acid, but is said to have the sp. gr. 0.866, which is much lower than that of any variety of the genuine oil. Rauitz (*Ph. Ztg.*, 1900, 261) states that Norwegian oil prepared by the cold process is often adulterated with the oil from a species of shark, *Scymnus vulgaris*. According to Kremel, fuming nitric acid causes instantly, when agitated with cod liver oil, a pinkish or rose-red color, which soon becomes brown, while no such effect is produced on other animal or vegetable oils. According to Winckler, the oil should afford the odor of herring pickle when heated with potassium hydroxide, lime and ammonium chloride. But the most reliable tests are the sensible properties of odor and taste. If there be none of the peculiar shoe leather odor and taste, or if a strong lamp oil odor be perceptible, the oil may be suspected. Little of importance can be inferred from the color.

Uses.—Although cod liver oil had been used as a folk remedy by the Dutch peasants for a long time, its introduction into regular medicine is attributable chiefly to the researches of Professor Bennett of Edinburgh in the middle of the nineteenth century. While its therapeutic value is not open to question, we are still ignorant as to what its medicinal properties are due. The idea, at one time quite prevalent, that its virtues resided in the small amount of iodine or phosphorus it contained, is scarcely tenable today; equally fallacious is the view that would attribute its efficacy to the organic bases such as morrhuine, etc. In 1914 Osborne and Mendel (*J. Bi. Chem.*, xvii, p. 401) showed that cod liver oil is very rich in fat soluble Vitamin-A, and a number of authorities have attempted to explain its value on the ground of its vitamin content. While this may be true of certain uses, it will not explain all the purposes for which the oil has been found useful. A most reasonable statement is that of Kirschner (*Amer. Rev. Tuberculosis,* 1922, vi, p. 401); he believes that the peculiar value is due in part to the fact that the unsaturated fatty acids are not only more completely absorbed in the intestines but also promote the absorption of other fats, and in part to the effects of some vitamin; he suggests also that there is some evidence that the unsaturated fatty acids directly increase the bodily resistance against tubercle bacilli.

The conditions in which cod liver oil is most frequently of service are: diseases of the bone, especially *rickets;* various forms of *tuberculosis;* and many forms of general *malnutrition.* That cod liver oil encourages the deposition of calcium salts in rickety bones has been demonstrated beyond cavil by researches of Hess (*J. A. M. A.,* 1921, lxxvi, p. 698), McCollum (*J. Bi. Chem.,* 1921, xlv, p. 343) and many others. Brown, MacLacklen and Simpson (*Amer. Journ. Dis. Child.,* June, 1920) have found that the use of cod liver oil in conjunction with calcium salts is of much benefit in the treatment of *tetany.*

While our faith in its usefulness in *phthisis* and other forms of tuberculosis must at present be based chiefly on empirical evidence, it seems, nevertheless, well established. The view commonly held today is that its benefit in these states is owing to its being a readily absorbed food stuff, but Williams (*B. M. J.,* 1912, ii, p. 700) believes that the unsaturated fatty acids have a direct inhibiting effect on the growth of the tubercle bacilli which may in part explain its action in tuberculosis. The idea of a specific influence in this infection is probably incorrect, but in the reaction against its use the pendulum has swung too far and it is ofttimes neglected or even condemned in cases in which it might be well employed. Cod liver oil is valuable in many conditions of undernourishment. Thus it is of service in those types of *chronic rheumatism* or *gout* which are associated with malnutrition, in some cases of *neurasthenia* and *neuralgia,* in infantile *marasmus* and nearly all wasting diseases in which it is acceptable to the digestive tract. It is unique among the oils in that it is absorbable through the skin, at least by young infants, in sufficient quantity to have a perceptible influence upon nutrition.

Various measures have been recommended for overcoming the objectionable taste which is a great obstacle to the wider use of this remedy. None of these, however, are entirely successful. It is most frequently exhibited in the form of one of the numerous emulsions upon the market, of which that with malt extract is one of the best. It is sometimes given in flexible capsules, but these have the objection that they can only hold comparatively small doses.

Dose, one to four fluidrachms (3.75–15 cc.).

OLEUM MYRCIÆ. N. F.

OIL OF MYRCIA

"A volatile oil distilled from the leaves of *Pimenta Acris* (Swartz) Wight (Fam. *Myrtaceæ*)." *N. F.*

Oil of Bay; Bayöl, *G.;* Essence de Bay, *Fr.*

This oil is obtained from the *Pimenta acris* Wight. The common name of "oil of bay" is very unfortunate as it is liable to lead to confusion with the aromatic oil obtained from the sweet bay (*Laurus nobilis*) or with that from the bay laurel (*Umbellularia Californica*). The official name of oil of myrcia is not much better, for it has long been recognized that the plant from which it is derived does not belong to the genus *Myrcia.*

The *Pimenta acris,* from the leaves of which this oil is obtained, is a small tree, native in the West India Islands. The flowers are white and borne in cymes. The fruit is a small globular berry resembling allspice. The large leathery leaves yield in the neighborhood of 3 per cent. of volatile oil. Two varieties of *P. acris* occur in coastal districts where the pure species abounds, and which are locally known as "Bois d'Inde Citronelle" and "Bois d'Inde Anise." The leaves of these are said to be frequently admixed with the leaves of the true bay to the great detriment of the oil subsequently distilled. The oil from the "Citronelle" variety (*P. acris* var. *citrifolia*) contains citral and possesses the flavor of lemon (*Kew Bull.,* No. 5, p. 158, 1918). According to the account of Franck (*P. J.,* 1921, cvi, 318), "The picking is best done in June, when men and boys break off smaller branches and carry them to the distilleries. Here the leaves are cooked in immense brass decanters, from which the bay oil is drawn off, and the leaves tossed out, apparently unchanged, except from green to coppery brown. One hundred and thirty pounds of leaves are required to produce a quart of oil."

Proper *bay rum* is the product directly distilled from the leaves of the bay tree. As described by Fishlock (*C. D.,* 1912, lxxxi, 714) either the fresh or dried leaves are employed; 200 pounds of the dried leaves are mixed with 65 gallons of rum and about 100 gallons of water, containing a little salt, and the whole of the distillate from this collected.

The commercial oil of bay is a mixture of both heavy and light oils, as G. M. Beringer found the specific gravity of two samples of undoubted purity to be 0.975 and 0.994. (*A. J. P.*, 1887, 286.) This is due to the complex character of the oil and the erratic manner in which it is distilled in the West Indies. The loss of the heavier fraction produces an inferior oil.

Description and Physical Properties.—"Oil of Myrcia is a yellow or brownish yellow liquid having a pleasant, aromatic odor and a pungent, spicy taste. With an equal volume of alcohol, glacial acetic acid, or carbon disulphide, it yields slightly turbid solutions. An alcoholic solution is slightly acid to litmus paper.

"Specific gravity: 0.962 to 0.990 at 25° C. It is lævorotatory, the angle of rotation not exceeding −3°, in a 100 mm. tube, at 25° C. When mixed with an equal volume of a concentrated solution of sodium hydroxide it forms a semi-solid mass. Dissolve 2 drops of the Oil in 4 cc. of alcohol, and add a drop of ferric chloride T.S.; a light green color is produced; if the same test is made with a drop of dilute ferric chloride T.S., prepared by diluting the test solution with 4 times its volume of distilled water, a light bluish coloration is produced, which soon disappears. Shake 1 cc. of the Oil with 20 cc. of hot distilled water and filter; the filtered aqueous solution does not give more than a scarcely perceptible acid reaction with litmus paper and on adding a drop of ferric chloride T.S. it yields only a transient, grayish green but not a blue or violet color (*phenol*).

"Preserve it in small, well-stoppered amber-colored bottles, in a cool place, protected from light." *N. F.*

Mittmann (*A. Pharm.*, 1889, 529) reported the following constituents: 1, pinene; 2, possibly dipentene; 3, a polyterpene, probably diterpene (insoluble in alcohol); these three in small quantity only; 4, eugenol, the chief constituent; and, 5, methyl-eugenol, in smaller quantity. It has since been examined by Power and Kleber (*Ph. Rund.*, 1895, 60) who state that it contains from 60 to 65 per cent. of phenols, of which two were identified: eugenol and chavicol, two phenol esters, methyl-eugenol, $C_{11}H_{14}O_2$, and methyl-chavicol, phellandrene and a newly discovered terpene which they named *myrcene*, $C_{10}H_{16}$, and citral, $C_{10}H_{16}O$. (*Ph. Rund.*, 1895, 60.)

Uses.—The oil of bay is an active antiseptic, 1 part in 1000, according to Peck (*J. A. M. A.*, 1899, xxxii, p. 6) being sufficient to prevent the growth of bacteria. It is, however, almost never employed in its unmixed state. In the form of the compound spirit, which is practically equivalent to bay-rum, it affords a pleasant perfume for various external medicines. It has also been used in cases of *nervous headache, faintness* and other *nervous disorders*, either held to the nostrils, or applied on soft linen to the head and forehead. According to Berger (*Th. M.*, 1907, xxi, p. 221), it is a valuable local application in various diseased conditions of the skin, especially in *seborrhea* of the scalp. It is also grateful to the feeble and convalescent patient, by being sprinkled on the bed covering or otherwise made to impregnate the air of the chamber. The oil of bay is often adulterated, and is frequently sold by smugglers.

OLEUM MYRISTICÆ. U. S., Br.

OIL OF MYRISTICA Ol. Myrist. [Myristica Oil Oil of Nutmeg]

"The volatile oil distilled from the dried kernels of the ripe seed of *Myristica fragrans* Houttuyn (Fam. *Myristicaceæ*)." *U. S.* "Oil of Nutmeg is the oil distilled from Nutmeg and rectified." *Br.*

Volatile oil of Nutmeg; Oleum Myristicæ Æthereum, Oleum Nucis Moschati, Oleum Nucistæ Æthereum; Huile volatile (Essence) de Muscade, *Fr.*; Oleum Macidis, *P. G.*; Aetherisches Muskatöl, Aetherisches Muskatnussöl, *G.*

This oil is obtained from nutmegs, after powdering them, by distillation with water, usually after the removal of their fat. Schimmel & Co. (1899) state that oil of nutmeg is made from the light, worm-eaten nuts, of which large quantities are rejected in sorting the different qualities in Holland; the worm robs the nutmeg of its fat oil, while the essential oil remains in the nut in full. According to Cushny (*Proc. Royal Soc. Med.*, 1908), nutmeg yields from 3 to 8 per cent. of volatile oil.

Description and Physical Properties.—"A colorless or pale yellow liquid, having the characteristic odor and taste of nutmeg.

"The oil is soluble in an equal volume of alcohol and in 3 volumes of 90 per cent. alcohol, by volume. Specific gravity: 0.859 to 0.924 at 25° C. Optical rotation: varies from +12° to +30° to a 100 mm. tube at 25° C. Refractive index: 1.4780 to 1.4895 at 20° C. A solution of the recently distilled Oil in an equal volume of alcohol is neutral or only slightly acid to moistened litmus paper. Evaporate 3 Gm. of the Oil in a small tared dish on a bath of boiling water: the weight of the residue does not exceed 0.006 Gm.

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

"Colorless or pale yellow. Odor and taste those of Nutmeg. Specific gravity 0.870 to 0.925; *optical rotation* +13° to +30°; *refractive index* at 25° C. 1.474 to 1.484. Soluble in 3 parts of *alcohol* (90 per cent.). Leaves not more than 5 per cent. of residue when evaporated on a water-bath." *Br.*

Power and Solway (*Tr. Chem. Soc.*, 1907, 2037) have analyzed the volatile oil of nutmeg and find that about 80 per cent. of it is dextro-pinene and dextro-camphene with about 8 per cent. of dipentene, besides small proportions of eugenol and iso-eugenol, linalool, borneol, terpineol, geraniol and safrol; they found about 4 per cent. of *myristicin*, small amounts of free myristic acid, and traces of esters of this and other fatty acids. Semmler (*B. Chem. G.*, 1890,

1803) examined an oil of myristica of sp. gr. 0.8611 which contained only terpenes; these boiled at about 50° C. under a pressure of 8 mm.

Myristicin, $C_{12}H_{14}O_3$, is of interest as the poisonous ingredient of nutmeg (see under *Uses*). It is the 3:4:5-trioxybenzene-methyl-methylene ether and has a melting point of 30° C.

Uses.—The oil of nutmeg unites to the common properties of the aromatics considerable narcotic power. It causes in the lower animals dilatation of the pupils, unsteadiness of the gait followed by sleepiness, with slow respiration, and, if the dose be large enough, loss of reflexes. According to Dale (*Proc. Royal Soc. Med.*, Feb., 1909), doses large enough to produce narcosis in the cat are invariably fatal through fatty degeneration of the liver. A number of fatal cases of nutmeg poisoning have been reported in human beings. For references to cases of nutmeg poisoning see Power and Solway (*A. J. P.*, 1908, 563). Cullen (quoted by above) reports a case in which 2 drachms of powdered nutmeg produce drowsiness deepening into stupor, the patient continuing for several hours alternately delirious and sleeping. Dale found that dose of 1.9 Gm. per kilo caused in a cat a semi-comatose condition with death in 24 hours with fatty degeneration of the liver.

The toxic ingredient in oil of nutmeg is undoubtedly myristicin. Dale found that myristicin caused similar symptoms but the quantity required was much larger than would be contained in a toxic dose of powdered nutmeg, the fatal dose of myristicin for a cat being between 0.5 and 1 cc. per kilo; Power and Solway suggest that this difference may be due to imperfect absorption and state that 2 minims (0.12 cc.) hypodermically, will produce in the cat extensive degeneration of the liver.

The oil of nutmeg is used to correct the taste of various drugs and as a local stimulant to the gastro-intestinal tract. It probably has also some value as a nerve sedative.

Dose, one-half to three minims (0.03–0.2 cc.).

OLEUM OLIVÆ. U. S., Br.

OLIVE OIL Ol. Oliv.

"The fixed oil obtained from the ripe fruit of *Olea europæa* Linné (Fam. *Oleaceæ*)." *U. S.* "Olive Oil is the oil expressed from the ripe fruit of Olea europæa, *Linn.,* and refined." *Br.*

Sweet Oil; Huile d'Olive, *Fr. Cod.;* Olivarum Oleum, *P. G;* Olivenöl, *G.;* Olio di olive, *It.;* Aceite de olivas, *Sp.*

Olea europæa L. is one of the leading fruit trees of the world. It is usually from fifteen to twenty-five feet in height, though sometimes much larger, especially in Greece and the Levant. It has a solid, erect, unequal stem, with numerous straight branches, covered with a grayish bark. The leaves are evergreen, firm, oblong or lanceolate, entire, two or three inches in length, smooth and of a dark green color on their upper surface, whitish and almost silvery beneath. The flowers are small, yellowish white, and disposed in opposite axillary clusters, about half as long as the leaves, and accompanied with small, obtuse, hoary bracts. The fruit, or olive, is a smooth, oblong or oval drupe, greenish at first, but of a deep violet color when ripe, with a fleshy mesocarp and a very hard endocarp. Clusters of not less than thirty flowers yield only two or three ripe olives.

The olive tree, which is probably native to western Asia or the eastern Mediterranean district, flourishes at present in all the countries bordering on the Mediterranean, and has been cultivated from time immemorial in Spain, the south of France, and Italy. It begins to bear fruit after the second year, is in full bearing at six years, and continues to flourish for a century. There are forty varieties, distinguished by the form of the leaves and the shape, color, and size of the fruit. The variety *longifolia* of Willdenow is said to be chiefly cultivated in Italy and the south of France, and the *latifolia* in Spain. The latter bears much larger fruit than the former, but the oil is less esteemed. The olive is largely cultivated in the north of Africa, especially in the vicinity of Tunis, southern California and other warm regions.

Olives are cultivated especially in Spain in the district of Cadiz. Two classes are produced, the one known as the "Queen olive," a large olive, which is mostly exported to the United States; the other the Manzanillo, or small olive, which is chiefly consumed in Spain, South America and Cuba.

Pickled olives, made by soaking green olives first in dilute solution of sodium hydroxide and then in salt water, are largely used as an article of food; the ordinary green olive of commerce has been picked before ripening. The ripe olive, which, in the United States, is chiefly obtained from California, is dark-purple, often almost black, very different in taste from the ordinary unripe pickled fruit, and is said to contain about 50 per cent. of olive oil, so that it affords an excellent method of administering fat.

There have been reported several epidemics of a peculiar form of food poisoning, known as *botulism,* from the eating of ripe olives which had been improperly preserved. This disease is caused by the *Bacillus botulinus,* or the toxins produced by it. It follows the use not only of olives, but of many other foods which have not been properly sterilized. The most prominent symptoms, which usually begin a few hours after the ingestion of the peccant food, are: Nausea, vomiting and diarrhea, with abdominal cramps, followed by constipation: there are severe nervous disturbances, especially of the visual apparatus—dilatation of the pupils, diplopia, and ptosis—loss of voice, dryness of the throat and great thirst, followed by exhaustion and, in many cases, death, sometimes preceded by delirium.

The leaves and bark of the olive tree have an acrid and bitter taste, and have been employed as substitutes for cinchona, though with no great success. In hot countries, a substance resembling the gum-resins exudes spontaneously from the bark. It was thought by the ancients to possess useful medicinal properties, but is not now employed. Analyzed by Pelletier, it was found to contain resin, a little benzoic acid, and a peculiar principle analogous to gum, which has been named *olivile*. But the fruit is by far the most useful product. In the unripe state the fruit is hard and insupportably acrid, but when macerated in water or an alkaline solution, and afterwards introduced into a solution of common salt it loses these properties, and becomes a pleasant and highly esteemed article of diet. Mannite has been found in all parts of the tree while in vital activity, as in the green leaves and unripe fruit, but cannot be detected in the yellow fallen leaves or in the perfectly ripe fruit.

The pericarp, or fleshy part of the ripe olive, abounds in a fixed oil, from 10 to 20 per cent., which constitutes its greatest value, and for which the tree is chiefly cultivated in southern Europe. The olives ripen from November to March, and the oil is obtained by first bruising them in a mill and then submitting them to pressure. The product varies much, according to the state of the fruit and the circumstances of the process. The best, called *virgin oil*, is obtained from the fruit picked before perfect maturity, and immediately pressed. It is distinguished by its greenish hue. The common oil used for culinary purposes and in the manufacture of soaps is procured from very ripe olives, or from the pulp of those which have yielded the virgin oil. In the latter case the pulp is thrown into boiling water, and the oil removed as it rises. An inferior kind, employed in the arts, especially in the preparation of the coarser soaps, plasters, unguents, etc., is afforded by fruit which has been thrown into heaps, and allowed to ferment for several days, or by the marc left after the expression of the finer kinds of oil, broken up, allowed to ferment, and again introduced into the press.

Description and Physical Properties.—" A pale yellow, or light greenish-yellow, oily liquid, having a slight, peculiar odor and taste, with a faintly acrid after-taste. Olive Oil is slightly soluble in alcohol, but is miscible with ether, chloroform, and carbon disulphide.

" Specific gravity: 0.910 to 0.915 at 25° C. When cooled to from 10° to 8° C., the Oil becomes somewhat cloudy from the separation of crystalline particles, and at 0° C. it usually forms a whitish granular mass. Mix 5 cc. of the Oil in a test tube with 5 cc. of a mixture of equal volumes of amyl alcohol and carbon disulphide, the latter containing 1 per cent. of precipitated sulphur in solution, and immerse the test tube to one-third of its depth in boiling, saturated aqueous solution of sodium chloride: no reddish color develops in fifteen minutes (*cottonseed oil*). Mix 2 cc. of the Oil with 1 cc. of hydrochloric acid containing 1 per cent. of sucrose, shake the mixture for half a minute, and allow it to stand for five minutes: on adding 3 cc. of distilled water to the mixture and shaking it, the acid layer shows no pink color (*sesame oil*). Saponify 10 Gm. of Olive Oil by heating it under a reflux condenser with a solution of 4 Gm. of potassium hydroxide in 80 cc. of alcohol for one hour. Neutralize exactly with diluted acetic acid, using phenolphthalein T.S. as indicator, and wash into 120 cc. of boiling lead acetate T.S. Boil the mixture for one minute, and cool by immersing the flask in cold water, occasionally rotating the contents to cause the precipitate to adhere to the sides of the flask. Decant the liquid, wash the precipitate with cold water to remove excess of lead acetate, then wash with 90 per cent. alcohol (by volume). Add 100 cc. of ether, cork well, and allow to stand until the precipitate is disintegrated. Connect with a reflux condenser, boil for five minutes, cool to about 15° C. and allow to stand over night. Filter, and thoroughly wash the precipitate of lead soaps with ether. Wash the precipitate into a 500 cc. separator by means of a jet of ether, alternating with diluted hydrochloric acid at the end, if a little of the precipitate adheres to the filter paper. Add enough diluted hydrochloric acid to make the total acid layer about 100 cc., and enough ether to make the total ether layer about 100 cc. and shake vigorously for several minutes. Allow the layers to separate, draw off the acid layer, and wash the ether once by shaking with 50 cc. of diluted hydrochloric acid and then with several portions of water until the water washings are no longer acid to methyl orange T.S. Transfer the ether solution to a dry flask, evaporate the ether, add a little dehydrated alcohol and evaporate on a steam bath. Dissolve the dry fatty acids by warming with 50 cc. of 90 per cent. alcohol (by volume), slowly cool the solution to 15° C., shaking frequently to aid crystallization, and allow the mixture to stand at 15° C. for thirty minutes. No crystals separate (*peanut oil*). Saponification value: not less than 190 and not more than 195. Iodine value: not less than 79 and not more than 90.

" Preserve in well-closed containers, in a cool place." *U. S.*

" Pale yellow or greenish yellow. Faint but not rancid odor; taste bland. Frequently assumes a pasty consistence when maintained for some time at a temperature of 10° C., and at a lower temperature may become a soft granular mass. Specific gravity 0.915 to 0.918; *saponification value* 188 to 197; *iodine value* 79 to 87; acid value not more than 6.0; *refractive index* at 40° C. 1.4605 to 1.4635. A mixture of 2 millilitres of the Oil with 1 millilitre of *amylic alcohol* and 1 millilitre of a solution (1 in 100) of *precipitated sulphur in carbon disulphide,* placed in a test-tube immersed in boiling *water*, does not assume a red color within thirty minutes (absence of cottonseed oil). When a mixture of 2 millilitres of the Oil and 1 millilitre of *hydrochloric acid* containing 1 per cent. of *refined sugar* is shaken for half a minute, and allowed to stand for five minutes, the acid layer does not become pink (absence of sesame oil). When 1 millilitre of the Oil and 15 millilitres of *N/1 alcoholic solution of potassium hydroxide* are boiled for twenty minutes in a flask provided with a reflux condenser, set aside for twenty-four hours at a temperature not exceeding 15.5° C., and afterwards heated on a water-bath for three minutes, the solution does not deposit crystals on standing for twenty-four hours further (absence of arachis oil)." *Br.*

The concrete portion, about 28 per cent of the oil, which separates at a freezing temperature, consists chiefly of the glyceride of palmitic acid, together with a smaller amount of glyceride of arachidic acid (stearic acid is stated by Hehner and Mitchell to be absent entirely); the liquid portion is essentially olein, with a small amount (seven parts for ninety-three of olein) of the glyceride of the less saturated linoleic acid. According to Braconnot, the oil contains 72 per cent. of olein and 28 of palmitin. A small quantity of phytosterin has also been found in the oil. Olive oil is solidified by nitrous acid and mercuric nitrate, and converted into *elaidin.* (See under *Olea Fixa.*)

The greenish color is owing to the presence of a trace of chlorophyll, and a trace of cholesterin is also extracted by repeated agitation with glacial acetic acid.

For discussion of the spectra of olive oil, see *P. J.*, 3d series, vii, 22, 110.

Olive oil, when exposed to the air, is prone to become rancid, acquiring a disagreeable odor, a sharp taste, and a thicker consistence; it also loses its color, and the change is promoted by heating it.

It is frequently adulterated with the cheaper fixed oils, especially with cottonseed oil, peanut oil, sesame oil and poppy seed oil. Of these, sesame is easily recognized; for peanut oil there is as yet no reliable color reaction, and while Bechi's reaction may, under certain conditions, answer well for the detection of cottonseed oil, this, under others, has also proven unreliable. (*Ph. Ztg.*, 1904, 104.) According to Kreis and Grob (*S. W. P.*, 1901, 88), Billier's test is very sensitive. It is carried out by shaking the suspected oil with a solution of resorcinol in benzene and afterwards with nitric acid. Olive oil under these circumstances remains unchanged in color, cottonseed and nut oil become red violet and maw seed oil is turned brown red. (See also official test for peanut oil.) Bechi's test for ascertaining the admixture of cottonseed oil with olive oil has received the approval of the Commission of Florence after most exhaustive experiments, and is as follows: One grain (0.065 Gm.) of silver nitrate is dissolved in fifteen minims (0.9 cc.) of water, and six and a half fluidounces (195 cc.) of alcohol are added. Two fluidounces (60 cc.) of ether may be added to render the solution more easily miscible with the oil, but it is not absolutely necessary. A solution of eighty-five parts of amyl alcohol and fifteen parts of rape seed oil is prepared. These reagents should not be kept on hand any length of time. To ten cc. of the oil to be examined one cc. of the solution of silver nitrate is added, and then from eight to ten cc. of the amyl alcohol reagent; the mixture is agitated strongly, and heated on a water bath for five or ten minutes. In the case of pure oils the color is unaltered by the addition of the reagents; if cottonseed oil be present, a brownish color or turbidity, varying from a light brown to a deep maroon or black (according to the extent of the adulteration), will be produced. (*A. J. P.*, 1887.) Milliau's test is a modification of the foregoing. If the fatty acids instead of the oil itself are treated with the same reagents, the same reduction of the silver salts occurs and the same brown color as in the Bechi test. Halphen's test with a mixture of amyl alcohol and carbon disulphide containing about 1 per cent. of sulphur in solution is now regarded as the most distinctive for cottonseed oil. For details see the official test. Lewkowitsch (*Chemical Analysis of Oils, Fats, and Waxes,* 2d ed., 1898, 462) says that the color reactions proposed by various authors are altogether unreliable and yield no definite results, with the exception of the color test (Baudoin's test, see *Oleum Sesami*) for sesame oil and perhaps Bechi's and Milliau's or Halphen's for cottonseed oil. Bulletin 77 (1905), of the Bureau of Chemistry, United States Department of Agriculture, showed that most of the spurious and adulterated olive oil in the United States was of domestic origin and that the oil as imported in original packages was mostly genuine. This has been verified by numerous other investigators during recent years. Since the passage of the Food and Drugs Act in 1906 it is rare to find a labelled container of olive oil adulterated, although much that is sold in bulk is still found to be spurious. In several states it has been judicially decided that the synonyms "sweet oil" and "salad oil" when unqualified mean olive oil. A low grade of olive oil used for soap making and other technical purposes is imported at a less rate duty than is collected on edible olive oil. The frequent use of such low grade oil for table purposes by those who are not particular about quality and flavor led to the requirement on the Part of the U. S. Treasury Department that such "technical oil" must be denatured for admission. There are three alternative and optional methods of denaturing. They consist in adding to the oil a small portion of oleoresin of capsicum, of oil of rosemary or of kerosene. Arachis oil, which is produced in large quantities in Marseilles, has been found in numerous samples of imported olive oil. According to

Tambon, the present-day adulterations do not consist in the addition of a single cheaper oil, but of ingeniously prepared mixtures of different oils in such proportions to each other that on analysis it becomes difficult or impossible to distinguish the adulterated from the genuine oil by the chemical and physical constants accepted for the latter.

Uses.—Olive oil is nutritious and mildly laxative and is often used in milder cases of chronic *constipation*, especially when associated with malnutrition. (See *J. A. M. A.*, 1919, lxxiii, 1441.) In the form of enema it is often a useful remedy in *fecal impaction*. It was formerly largely used in the treatment of *gall stones* with the idea that it stimulated the secretion of bile. The concretions which were passed by these patients, however, were shown to be masses of hardened soap and it is extremely questionable whether the oil has any real value in this disease. Externally it is useful to soften and relax the skin and to protect it against the action of the air. The most extensive use of olive oil is in pharmacy as a constituent of liniments, ointments, cerates, and plasters.

Dose, as a laxative, from one-half to two fluidounces (15–60 cc.).

Off. Prep.—Linimentum Ammoniæ, *Br.;* Linimentum Calcis, *Br.;* Linimentum Camphoræ, *Br.;* Oleum Phenolatum, *N. F.;* Unguentum Fuscum, *N. F.*

OLEUM PHOSPHORATUM. Br.

PHOSPHORATED OIL

"Phosphorated Oil contains 1 per cent. by weight of Phosphorus. It should be freshly prepared." *Br.*

Huile phosphorée, *Fr. Cod.;* Liniment phosphoré, *Fr.;* Phosphorhaltiges Oel, *G.;* Aceite fosforado, *Sp.*

"Phosphorus, 1 *gramme;* Almond Oil, previously heated to 150° C., cooled and filtered, 98 *grammes;* Oil of Lemon, 1 *gramme.* Add the Phosphorus to the Almond Oil contained in a stoppered bottle capable of holding rather more than the required quantity; warm to about 80° C., and shake until the Phosphorus is entirely dissolved; cool, and add the Oil of Lemon. A clear, pale-yellow liquid, phosphorescent in the dark." *Br.*

Phosphorated oil was not retained in the U. S. P., but has been admitted to the N. F. (see Part III).

The object of heating the oil is to expel air and traces of water, which would oxidize the phosphorus. The ether not only assists in the preservation of the finished preparation, but is also of use in rendering the oil less disagreeable to the taste. E. R. Squibb passes a current of carbon dioxide through the oil contained in the bottle in which it is to be kept, to expel the air and prevent oxidation.

This is a clear and colorless or but slightly colored oil, phosphorescent in the dark, and having the odor and taste of phosphorus quite distinctly. It should be perfectly free from any particles of undissolved phosphorus. It may be administered in the form of an emulsion, like the official almond emulsion, and flavored with oil of bitter almond, or preferably in capsules; each minim contains a little less than one one-hundredth of a grain of phosphorus.

Dose, one to two minims (0.06–0.13 cc.).

OLEUM PICIS RECTIFICATUM. U. S.

RECTIFIED OIL OF TAR Ol. Pic. Rect. [Oleum Picis Liquidæ Rectificatum, U. S. P. IX]

"The volatile oil from pine tar rectified by steam distillation." *U. S.*

Rectified Tar Oil; Oil of Tar; Oil of Pine Tar; Huile volatile de Goudron, *Fr.;* Theeröl, Pechöl, *G.*

This oil is prepared by distilling wood tar, the residue left in the still being known as pitch. It represents thoroughly the medicinal properties of tar, and is preferable on account of its less offensive taste.

Description and Physical Properties.—"A thin liquid, having a dark reddish-brown color, and a strong, empyreumatic odor and taste.

"The oil is soluble in all proportions in alcohol. Specific gravity: 0.960 to 0.990 at 25° C. An alcoholic solution of the Oil is acid to moistened blue litmus paper." *U. S.*

For composition of this oil see *Pix Pini.*

The thick tarry oil of high viscosity and almost black color, found upon the market and frequently supplied for oil of tar, does not comply with the U. S. P. requirements of sp. gr., as it is usually much heavier than water, while the U. S. P. is lighter.

Uses.—The oil of tar is used chiefly in the treatment of *chronic bronchitis.* Its action is practically the same as that of creosote, which is indeed its most important constituent. It may be administered either in emulsion or by dropping it on sugar. It is often added to boiling water for inhalation in the proportions of five to ten minims to a pint. It is also used externally in various *skin diseases.*

Dose, one to five minims (0.06–0.3 cc.), administered in capsule or in emulsion.

Off. Prep.—Unguentum Picis Compositum, *N. F.;* Syrupus Picis Pini, *U. S.*

OLEUM PIMENTÆ. N. F.

OIL OF PIMENTA Ol. Piment. [Oil of Allspice Pimento Oil]

"A volatile oil distilled from the fruit of *Pimenta officinalis* Lindley (Fam. *Myrtaceæ*), yielding not less than 65 per cent., by volume, of eugenol [$C_{10}H_{12}O_2$ (164.15)]." *N. F.*

Oleum Amomi; Oil of Pimento; Huile volatile (Essence) de Piment de la Jamaïque, *Fr.;* Nelkenpfefferöl, Pimentöl, *G.*

Oil of pimenta was deleted from the British Pharmacopœia 1914, and from the U. S. X, but is recognized by the N. F. V.

The berries of the allspice (see *Pimenta*) yield from 1 to more than 4 per cent. of the volatile oil, which as found in commerce is brownish-red, and has the odor and taste of pimenta, though warmer and more pungent. It has a slightly acid reaction.

Description and Physical Properties.—"Oil of Pimenta is a colorless, yellow or reddish liquid, becoming darker with age and having the characteristic odor and taste of allspice. It is soluble in an equal volume of 90 per cent. alcohol; also soluble in 2 volumes of 70 per cent. alcohol.

"Specific gravity 1.018 to 1.048 at 25° C. The optical rotation varies from 0° to –4° in a 100 mm. tube at 25° C.

"**Assay.**—Introduce 10 cc. of the oil into a flask with a long graduated neck (cassia flask) add 50 cc. of sodium hydroxide T.S., shake the mixture for five minutes and then heat it on a water bath during ten minutes, cool and when the liquids have separated completely add sufficient sodium hydroxide T.S. to raise the lower limit of the oily layer within the graduated portion of the neck and note the volume of the residual liquid. The residual liquid measures not more than 3.5 cc. indicating the presence of not less than 65 per cent. by volume, of eugenol.

"Preserve it in well-stoppered amber-colored bottles, in a cool place, protected from light." *N. F.*

Oil of pimenta contains from 60 to 75 per cent. of eugenol; the remainder is chiefly a sesquiterpene, whose exact composition has not been determined. There is present also a small amount of resin and an unknown odorous principle. Oil of pimenta, therefore, is analogous in its constitution to oil of clove (see *Oleum Caryophylli*). Nothing is known of the constituents which give oil of pimenta its characteristic odor.

Oil of pimenta is given for the same purposes as are the other stimulant aromatic oils.

Dose, from one to five minims (0.06–0.3 cc.).

Off. Prep.—Liquor Pepsini Aromaticus, *N. F.;* Spiritus Myrciæ Compositus, *N. F.*

OLEUM PINI PUMILIONIS. U. S.

OIL OF DWARF PINE NEEDLES Ol. Pin. Pumil.

"The volatile oil distilled from the fresh leaves of *Pinus montana* Miller (*Pinus Pumilio* Haenke) (Fam. *Pinaceæ*). Oil of Dwarf Pine Needles yields not less than 5 per cent. of esters calculated as bornyl acetate [$C_{10}H_{17}.C_2H_3O_2$]." *U. S.*

Oleum Pini, *Br., 1898;* Oil of Pine; Dwarf Pine Oil; Pine Needle Oil; Latchenkieferöl, Krummholzöl, *G.;* Oleum templinum, Pumiline.

Beissner, in his *Handbuch der Nadelholzkunde,* considers *P. Pumilio* Haenke, a synonym of *P. montana* Mill., whereas in the *Index Kewensis* the latter is brought under the former. Most authors agree with De Candolle and Beissner in bringing *P. Pumilio* Haenke, under *P. montana* Mill. The latter known as *Swiss Mountain Pine* varies in habit from a low shrub to a pyramidal tree which attains a height of 40 feet. Its branchlets are brownish and bear bright green acute leaves in fascicles of 2 and up to 2 inches in length. Its cones are ovate or conic-ovate and from ¾ to 2¼ inches long. It is a native of the mountains of Central Europe. The exudate obtained by cutting off the branches is called *Hungarian Balsam.*

The volatile oils of several of the coniferous trees are used for medicinal purposes and different ones have from time to time been official in several countries.

The Br. 1885 recognized, under the name of *Oleum Pini,* an oil from the leaves of the *P. sylvestris* L. but this has been replaced by a similar product from the Siberian Fir (see *Oleum Abietis*). The U. S. P. recognizes that from the leaves of the *mountain pine.*

Description and Physical Properties.—"A colorless or faintly yellowish liquid, having a pleasant, aromatic odor, and a bitter, pungent taste.

"The Oil is soluble in 10 volumes of 80 per cent. alcohol, by volume. Specific gravity: 0.853 to 0.869 at 25° C. Optical rotation: varies from –4° 30′ to –9° in a 100 mm. tube at 25° C. Refractive index: 1.4750 to 1.4800 at 20° C. A solution of the recently distilled Oil in 80 per cent alcohol (1 in 10) is neutral or only slightly acid to moistened litmus paper. Less than 1 per cent. of the Oil distils below 165° C.

"**Assay.**—Proceed as directed for esters under *Oleum Menthæ Piperitæ,* using 10 cc. of Oil of Dwarf Pine Needles. Multiply the number of cc. of half-normal alcoholic potassium hydroxide consumed in the saponification, by 9.811, and divide the product by the weight of the Oil taken. The result shows the per cent. of esters calculated as bornyl acetate.

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Pine oil contains lævo-pinene, lævo-phellandrene, sylvestrene, *bornyl acetate,* and in the last portions of the distillate, cadinene. (Gildemeister and Hoffmann, *Aetherische Oele,* p. 338.) It is supposed that the pine oil owes its odor to the presence of the acetic ester of borneol, which is ordinarily present to the amount of about 3.5 per cent., and Schimmel & Co. (*Schim. Rep.* for Oct., 1897) found in a sample of American fir oil as much as 12.1 per cent.

Under the name of *templin oil* a volatile oil from the cones is sold. It is much lighter in density than the leaf oil and has a higher optical rotation, and contains a greater proportion of esters. (*Perf. & Ess. Oil Rec.,* 1915, vi, p. 165.) Both the cones and leaves of *Abies Picea* yield oils known respectively as *pine cone oil* and *pine needle oil.* According to *Schimmel's Report* for April, 1897, they both contain pinene, limonene, and bornyl acetate. The oil from *Pinus sylvestris,* known as *fir oil,* also contains bornyl acetate to the amount of 12 per cent. according to *Schimmel's Report* for October, 1897, 47. On the other hand, the oil from *Larix Europæa,* known as *larch needle* *oil,* contains 8.1 per cent. of bornyl acetate and 6.14 per cent. of free borneol. (*Ibid.,* 61.)

Uses.—In medicine it may be employed for many of the purposes for which oil of turpentine has been used. As an expectorant in *chronic bronchitis* it may be administered by the mouth but is especially prized as an inhalant because of its pleasant odor. For this purpose a few drops may be placed in boiling water and the vapors inhaled. It has also been employed internally in the treatment of *chronic rheumatism.*

The leaves of the *Pinus sylvestris,* with those of other European firs and pines, by pounding are converted into a fibrous substance, known as *fir wool* (*Fichtenwolle*), which is used in Germany as a local application in *chronic rheumatism,* the affected part being enveloped in a thick batting of the fir wool, which is also sometimes made into clothing for rheumatic persons. An extract of the leaves is also sold under the name of *fir wool extract,* for use in rheumatism.

Dose, of oil of pine needles, five to ten minims (0.3–0.6 cc.).

OLEUM RICINI. U. S., Br.

CASTOR OIL Ol. Ricin.

"The fixed oil obtained from the seeds of *Ricinus communis* Linné (Fam. *Euphorbiaceæ*)." *U. S.* "Castor Oil is the oil expressed from the seeds of Ricinus communis, *Linn.*" *Br.*

Huile de Ricin, *Fr. Cod.;* Oleum e semine Ricini, *Fr.;* Ricinusöl, *G.;* Olio di ricino, *It.;* Aceite de ricino; Oleum Palmæ Christi, *Sp.*

The castor oil plant, or *palma Christi,* is a native of India and is now extensively cultivated in the warmer regions throughout the world. In India there are about seventeen different varieties grown which are grouped into two types: The first consists of tall shrubs or small trees, being usually planted as a shade for other crops and yielding large seeds which contain an abundance of inferior oil. The second type includes the herbaceous annuals, which, while they produce small yields, yield a much better grade of fixed oil.

The following description applies to the plant as cultivated in cool latitudes. The stem is of vigorous growth, erect, round, hollow, smooth, glaucous, somewhat purplish towards the top, branching, and from three to eight feet or more in height. The leaves are alternate, peltate, palmately six to eleven lobed, the lobes acute or acuminate and serrate, smooth on both sides, and of a bluish-green color. The flowers are monœcious, stand upon jointed peduncles, and form a pyramidal terminal raceme, of which the lower portion is occupied by the male flowers, the upper by the female. Both are destitute of corolla. In the staminate flowers the calyx is divided into five oval, concave, pointed, reflected, purplish segments, and encloses numerous stamens, united into fasciculi at their base. In the pistillate the calyx has three or five narrow lanceolate segments, and the ovary, which is roundish and three-sided, supports three linear, reddish stigmas, forked at their apex. The fruit is a roundish, glaucous capsule, with three projecting sides, covered with tough spines, and divided into three loculi, each containing one seed, which is expelled by the bursting of the capsule. The seeds are now produced in commercial quantities in India, the Islands of West Indies, South America, and southern, middle and western United States. Those supplies received from India have contained less impurities than the supplies of castor seeds from the West Indies and South America. The impurities found in commercial supplies include hulls, sand, stones, pebbles, black, broken, decorticated and immature castor seeds. Black "beans" (seeds) are those whose kernels have become discolored as a result of the seeds having been wet. Black, decorticated and broken beans, if not removed from the stock, have the effect of increasing the acidity of the oil produced therefrom. An interesting and valuable article on the cultivation of the castor bean in the United States appears in the *Proc. P. Ph. A.,* 1916, p. 209, by Joseph L. Lemberger. The flowers appear in July, and the seeds ripen successively in August and September. A decoction or poultice of the leaves is sometimes used as a local galactagogue, and an infusion has been given internally for a similar purpose.

1. The Seeds.—These are from 8 to 18 mm. long and 4 to 12 mm. broad, oval, compressed, obtuse at the extremities, very smooth and shining, and of a grayish or ash color, marbled with reddish-brown spots and veins. At one end of the seed is a small yellowish caruncle, from which an obscure longitudinal ridge proceeds to the opposite extremity, known as the raphe. In its general appearance the seed is thought to resemble the insect called the *tick,* the Latin name of which has been adopted as the generic title of the plant. Its variegated color depends upon a very thin pellicle closely investing a hard, brittle, blackish, tasteless, easily separated shell, within which is the kernel, highly oleaginous, of a white color, and of a sweetish taste succeeded by a slight degree of acrimony. The seeds easily become rancid, and are then unfit for the extraction of the oil, which is acrid and irritating. G. J. Scattergood found the odor of castor oil to be developed in the beans when bruised with water, and much more powerfully in those long kept than in the fresh. The water distilled from the seeds has a peculiar nauseous odor, quite distinct from that of the oil.

The seeds are active poisons; three have produced fatal gastro-enteritis in the adult. Their poisonous action, as first shown by Stillmark in 1889, is due to an albumose called *ricin.* This has been obtained as a white amorphous powder soluble in water, neutral in reaction. It is so actively poisonous that 0.002 milligramme is sufficient to kill a rabbit. It is a peculiarly interesting substance because when injected in small doses the body produces an antitoxin precisely analogous to those produced against bacteria. Commercially ricin has been employed for the detection of pepsin. For details of the method see Solms. (*Z. K. M.*, 1907.)

The most important constituent of the castor bean is the fixed oil, of which they yield about 50 per cent. The cake left after the expression of the oil known as *castor pomace* contains a nitrogenous crystallizable body which differs from the alkaloids in not forming salts with acids. This substance, which was first described by Tuson in 1864 and named by him *ricinine,* has been reinvestigated by Phillippe and Maquerme (*Proc. A. Ph. A.*, 1904, 950); they regard it as a dimethyl-ester of ricinic acid and assign a formula $C_8H_8O_2N_2$. Böttcher who prepared 450 grammes of the alkaloid from 300 kilos of castor beans finds the pure alkaloid to melt at 200° C. and upon hydrolysis with potassium carbonate to yield ricininic acid melting at 298° C. He questions the formula assigned by Phillippe and Maquerme. A typical zymogen is also present. It is soluble in fats and in a mixture of fats and ethyl ether, and is activated by acids.

Castor seeds consist of 20 per cent. of husks, which are rich in mineral constituents but contain no oil, and 80 per cent. of kernels. The whole seeds contain about 50 per cent. of oil. One of the early methods of obtaining castor oil was boiling the seeds with water and skimming off the separated oil. This has long since been abandoned for less wasteful methods. Two methods may be economically used—extraction with an appropriate solvent, or expression. Some oil has been produced in European countries by extracting the ground seed with petroleum benzin or alcohol but the oil as obtained by extraction is not as satisfactory for medicinal use as that obtained by expression.

The expression may be hot or cold. The seeds are first decorticated by being passed between properly adjusted rollers and the kernels are separated from the husks by an air blast. The medicinal oil is expressed cold, or with the kernels not warmer than 50° C. as above this temperature ricinine is dissolved. The residue is sometimes expressed a second or even a third time, with elevation of the temperature. These later fractions of oil are used for industrial or soap making purposes. The press cake called *castor pomace* is unfit for feeding animals as it contains the poisonous constituents of the seed. Attempts have been made to free the press cake from these poisonous principles by different methods of treatment, but no castor press cake has been produced on the large scale that is safe for feeding purposes. The press cake therefore finds its principal use as a fertilizer. About 40 per cent. of oil is obtained by expression, 33 per cent. in the first pressing and the balance in the later pressings. A "cage" hydraulic press is used in the pressing operation. Extraction of the remaining oil from the press cake is frequently accomplished by the use of very elaborate extraction apparatus known as a "rotary extractor."

The albuminous principles which may have accompanied the oil are then removed by steaming, which also destroys any of the enzyme that might be present and it is finally filtered. If not of satisfactory color it may be bleached by treatment with fuller's earth and filtration.

India was for many years the world's principal production point for castor oil, Marseilles, France, coming next. During the World War castor oil was used extensively as a motor lubricant for aeroplanes. The supplies from India were cut off in the early part of the war by the destruction of shipping and a great scarcity was threatened. In both Great Britain and the United States all stocks of high grade castor oil were seized, the lower grades being left for medicinal use. Its qualities as an aeroplane lubricant are discussed by C. Frabot, *Ann. Chim.,* 1918, 81. The cultivation of the castor plant was urged in many parts of the United States, particularly in the southern States, but the attempts were usually unsuccessful. See Grosh, *D. C.,* 1914, p. 197 and J. L. Lemberger, *Proc. Penna. Ph. A.,* 1920, p. 155. In 1918 supplies began to come in more rapidly. India furnished eight million pounds to Great Britain alone and the rest of the world was supplied principally by Japan, and Java, each of which countries exported nearly two million pounds. The United States produced some but not very much.

Properties.—Pure castor oil is a thick, viscid, colorless liquid, with little odor, and a mild though somewhat nauseous taste, followed by a slight sense of acrimony. As found in commerce it is often tinged with yellow and has an unpleasant odor, and parcels are sometimes, though rarely, met with of a brownish color and hot acrid taste. It does not readily congeal by cold. When exposed to the air it slowly thickens, without becoming opaque. When exposed to the air in a thin layer, it slowly dries to a varnish-like film. It is heavier than most of the other fixed oils. It differs also from most other fixed oils in being miscible in all proportions with cold absolute alcohol.

It is officially described as: "A pale yellowish or almost colorless, transparent, viscid liquid. It has a faint, mild odor, and a bland, afterwards slightly acrid and usually nauseating taste. Castor Oil is miscible with dehydrated alcohol and with glacial acetic acid.

"Specific gravity: 0.945 to 0.965 at 25° C. Castor Oil is only partly soluble in petroleum benzin (*difference from most other fixed oils*), but it yields a clear liquid with an equal volume of alcohol (*foreign fixed oils*). Dissolve 2 Gm. of Castor Oil in 20 cc. of alcohol, which previously has been neutralized with tenth-normal sodium hydroxide, using 5 drops of phenolphthalein T.S. as indicator, and titrate with tenth-normal sodium hydroxide to the production of a pink color which persists for fifteen seconds: not more than 1.5 cc. of tenth-normal sodium hydroxide is required (*free acid*). Saponification value: not less than 179 and not more than 185. Iodine value: not less than 83 and not more than 88.

"Preserve in well-closed containers." *U. S.*

"Nearly colorless, or with a yellowish tinge, viscid. Liable to solidify at low temperatures. Slight odor; taste at first bland, but afterwards acrid and unpleasant. Specific gravity 0.958 to 0.970; *saponification value* 177 to 187; *iodine value* 83 to 90; *acid value* not more than 4.0; *refractive index* at 40° C. 1.4695 to 1.4730. Soluble in all proportions of *absolute alcohol,* and in 3.5 parts of *alcohol* (90 per cent.). 10 millilitres shaken with 7 millilitres of *petroleum spirit* in a stoppered glass cylinder form a clear mixture at 15.5° C.; on shaking with a further addition of 3 millilitres of *petroleum spirit* a turbid mixture is formed, which becomes clear when maintained for five minutes at 21° C., but again becomes turbid when the temperature falls below 18° C. (absence of other fixed oils)." *Br.*

The bulk of castor oil is *ricinolein,* which is the *ricinoleic acid* ($C_{18}H_{34}O_3$) glyceride. At the same time it also contains a small quantity of tristearin and of the glyceride of dihydroxystearic acid, together with from 0.30 to 0.37 per cent. of unsaponifiable matter. Ricinoleic acid, as obtained from the decomposition of the glyceride is a viscid oil, which solidifies below 0° C., does not solidify in contact with the air by absorption of oxygen, and is not homologous with oleic or linoleic acid, neither of which is found in castor oil. On warming with 1 part of starch and 5 parts of nitric acid (sp. gr. 1.25) castor oil thickens, owing to the formation of *ricinelaidin.* From this *ricinelaidic acid* may be obtained in brilliant crystals. Ricinoleic acid is converted by potassium hydroxide into caprylic alcohol and sebacic acid, with disengagement of hydrogen, and the same products are obtained by the reaction of potassium hydroxide with the oil itself. (See *J. P. C.,* 1885, 113.) Castor oil differs from most other fixed oils in turning the plane of polarized light to the right.

By the action of concentrated sulphuric acid upon castor oil is formed a valuable product known as "*Turkey-red oil,*" much used in dyeing and printing with madder and alizarine (See *Sodium Sulphoricinate,* Part II.)

Castor oil which is acrid to the taste may sometimes be rendered mild by boiling it with a small proportion of water. If turbid, it should be clarified by filtration through coarse paper. On exposure to the air it is apt to become rancid, and is then unfit for use.

Twombly finds that the best method for removing the odor and taste of castor oil is by washing a cold pressed oil several times with boiling water. After separating, the oil is filtered cold very slowly through a thick layer of powdered animal charcoal. Any effort to quicken the method gives poor results. Several manufacturers are now producing a castor oil which is practically free from the characteristic unpleasant flavor and which appears to be equally efficacious as a medicine.

Uses.—The cathartic effects of castor oil are due to its ricinoleic acid which is split off in the intestinal tract. This, by gentle irritation of the mucous membrane, excites active peristalsis in the upper bowel and probably also somewhat increases the intestinal secretions, although the main action appears to be due to the increased peristalsis. Because of the thoroughness with which it empties the enteric canal there is on the following day an insufficient accumulation of intestinal contents and hence constipation is liable to follow. Because it cleans out the whole alimentary system and that with relatively small degree of irritation, it is especially valuable in conditions of irritation or inflammation of the bowels, as *colic, enteritis,* or *dysentery;* on account of the tendency to subsequent constipation it is not to be recommended as a habitual laxative. It is frequently resorted to in cases of *pregnant* and *puerperal women,* and is decidedly, as a rule, the best and safest cathartic for children. Infants usually require a larger relative dose than adults.

Externally it is useful for its emollient effects in *seborrhea* and other *skin diseases,* having the advantage over other oils of being soluble in alcohol.

The *dose* for an infant is from one to three fluidrachms (3.75–11.25 cc.). It is difficult of administration from its peculiarly disagreeable taste and from its oleaginous and viscid character. In a few cases, the disgust which it excites is utterly unconquerable by any effort of resolution. A common method of disguising the taste is to give it floating in cinnamon water or orange-juice but that which we have found, upon the whole, the least offensive is to give it floating on the froth of sarsaparilla syrup mixed with carbonic acid water. It is sometimes administered advantageously in a sweetened, aromatized emulsion. It is stated (*Bull. Pharm.,* 1920, xxxiv, p. 479) that the Arabs successfully mask the taste of castor oil by stirring it with heated milk, which forms a perfect emulsion, and flavoring this with syrup of orange flowers. Another method of disguising its taste is to add a drop of one of the aromatic oils, as cloves or wintergreen, and pour the oil in a chilled spoon which is laid on a cake of ice, when the oil becomes semi-solid and can be swallowed in a mass before it melts. Tragacanth has been recommended as producing a better emulsion than gum arabic. Castor oil may also be used as an enema, in the quantity of two or three fluidounces (60 or 90 cc.), mixed with some mucilaginous liquid.

Dose, from one-half to two fluidounces (15–60 cc.).

OLEUM ROSÆ. Br.

OIL OF ROSE

"Oil of Rose is the oil distilled from the fresh flowers of Rosa damascena, *Linn.*" *Br.*

Oleum Rosarum; Attar or Otto of Rose; Huile volatile de Rose pâle, *Fr. Cod.;* Essence de Rose, *Fr.;* Oleum Rosae, *P. G.;* Rosenöl, *G.;* Essenza de rose, *It.*

Fats and oils saturated with the rose perfume have been used since the earliest times. Of the seven thousand or more cultivated varieties of rose only a few are used for the production of oil. The chief of these is *Rosa damascena* or *damask rose,* a shrub whose habitat is unknown but which was introduced to Europe from Asia Minor in the 16th century. It attains a height of 5 feet and is further characterized by possessing stems covered with many stout, hooked prickles and glandular bristles, imparipinnate leaves with 5 to 7 ovate-oblong, serrate leaflets, pubescent on their lower surfaces, prickly petioles, red, pink or white flowers, borne in corymbs, and obovate hip fruits. The volatile oil from this species is commonly called *attar, otto,* or *essence of roses.* It is prepared on a large scale in Europe, especially in the Balkan Mountains, in Egypt, Persia, Cashmere, India, and other countries of the East, but European and American commerce is at present supplied chiefly from the region constituting the southern slope of the Balkans in Bulgaria, the town of Kizanlik being the most important center of production. The roses are gathered in May, and are distilled with the green leaves of the calyx. From thirty to sixty pounds are put into a tinned copper boiler, of the capacity of about 150 pounds, nearly filled with water. The heat is applied over an open fire, and a boiling temperature is continued for two hours, when the first part of the distilled fluid is returned to the boiler, and the process is continued to completion. The oil collects on the top of the water in the receiver, when it is removed from time to time as it accumulates. In the south of France a small quantity of oil of rose is prepared by distilling the petals with water and separating the oil which floats to the surface. The annual output of oil is small, most of it being marketed in the form of rose water.

The quantity of oil yielded by roses is very small, from 150 to 300 pounds being required to produce a single ounce of the oil. The price is correspondingly high; at present (1924) it is about $20 to $30 an ounce.

The experiments of Schimmel are said to indicate that the oil of rose can be prepared from German-grown flowers with commercial success. It is affirmed that the product is superior to the Turkish oil in fineness and strength of aroma, and also that it differs in having a higher congealing point, German oil solidifying at 32° C., Turkish oil at 20° C. For an account of its production, see *P. J.,* 1893, 262; also *J. S. C. I.,* 1919, xxxix, 43A.

For accounts of the modern rose industry see Tschirch, *Seifenseider Ztg.,* 1921, xlviii, and Chipkoff, *Bull. Sc. Pharm.,* 1921, xxviii, 389. Srivastava and Sinha give an account of the manufacture of otto from Indian rose. (*Perf. & Ess. Oil Rec.,* 1921, xii, 14.) Lorgues (*C. D.,* 1920, xciii, 1629) describes the French rose industry.

Oil of rose is nearly colorless, or presents some shade of green, yellow, or red, but, according to Polier, the color is no criterion of its value. Its odor is very powerful and diffusive. Alcohol dissolves it, although not freely when cold. Although described by the Br. as a "semi-solid," at the temperatures ordinarily met with in the United States it is liquid.

"A pale yellow or yellowish-green crystalline mass, semi-solid at ordinary temperatures. Strong, fragrant, rose-like odor; taste sweetish. Specific gravity at 30° C. (compared with *water* at 15.5° C.) 0.854 to 0.862; *optical rotation* –2° to –4°; *refractive index* at 25° C. 1.456 to 1.465; melting point 20° to 23° C." *Br.*

Oil of rose consists of two portions, one liquid, the other solid at ordinary temperatures. These may be separated by freezing the oil and compressing it between folds of blotting paper, which absorbs the liquid oil and leaves the concrete stearopten. The liquid portion is oxygenated, while the solid portion, which is odorless when pure, consists of a mixture of several hydrocarbons, one of which melts at from 35.5° to 36.5° C., and is a paraffin of the formula $C_{16}H_{34}$. "The addition of 70 per cent. alcohol precipitates the paraffin hydrocarbons of the oil, but forms a clear solution with its other constituents, the solution being slightly acid to litmus T.S." *U. S. VIII.* The oxygenated portion consists of the two alcohols, geraniol, and citronellol, together constituting 75 per cent. of the oil. The *rhodinol* of Eckart was a mixture of these two alcohols. (*Schim. Rep.,* April, 1898, 40.) While these two alcohols are mainly found in rose oil in the free state, esters of the same are also present in amounts varying from 2.5 to 3.5 per cent. (Gildemeister and Hoffmann, *Aetherische Oele,* p. 565.) Linalool, citral and phenyl ethyl alcohol are also present in small amounts as are also nerol, farnesol, eugenol, linalol and nonylic aldehyde.

The U. S. P. VIII considered the saponification value as of sufficient importance to incorporate it as an official test, as follows:

Assay.—"Place in a weighing-bottle about 2 cc. of the Oil of Rose, and weigh accurately. Transfer it, with the aid of a little alcohol, to a 100 cc. flask, and add 20 cc. of half-normal alcoholic potassium hydroxide V.S. Connect the flask with a reflux condenser, and boil the mixture during thirty minutes on a water-bath. When cool, add 50 cc. of distilled water and a few drops of phenolphthalein T.S., and titrate with half-normal sulphuric acid V.S. Subtract the number of cc. of half-normal sulphuric acid V.S. required, from 20 (the 20 cc. of half-normal alcoholic potassium hydroxide V.S.

taken), multiply the difference by 27.87, and divide by the weight of the Oil to obtain the saponification value." *U. S. VIII.*

Oil of rose is frequently, one might almost say usually, adulterated with various fixed or volatile oils; among those most commonly met are spermaceti, oil of rose-geranium (see *Pelargonium,* Part II) and oil of palmarosa (see *Oil of Citronella,* Part II). Some of these falsifications are very difficult of detection. An adulteration with a fixed oil produces a permanent greasy stain upon paper, and spermaceti is left behind on the evaporation of a few drops of the oil from a watch crystal in a water bath. Massatsch (*Ph. Ztg.,* 1923, lxviii, 832) states that to be certain of the purity of rose oil, the following characters must be determined: specific gravity, optical rotation, congealing point, refractive index, stearopten content, saponification number and alcohol content. He gives the following constants for a good oil: sp. gr. 0.849–0.862, congealing point 18–23.5° C., acid number 0.5–3.0, ester number 7–16, saponification number 7.5–19, alcohol content 66–75 per cent., stearopten 17–21 per cent.

Tedermann (*Zeit. An. Chem.,* 1895, 5) reached the conclusion, after much experimenting that there is no reliable chemical or physical test for the adulteration of oil of rose with geranium oil. The sense of smell, according to Conroy, furnishes the best means of determining the quality; he recommends the dissolving of one drop of oil of rose in twenty drops of alcohol, pouring the solution in one fluidounce of warm water, shaking, and comparing the odor with that of a standard sample treated in the same way. (*P. J.,* 1896 474; see also *C. D.,* 1897, 53.) For other tests which have been suggested see *U. S. D.,* 20th ed., p. 787.

Synthetic rose oils are now manufactured and sold on a large scale. Most of them contain a certain proportion of true rose oil, for the reproduction of the odor by synthetic constituents alone has never been achieved. *Rhodinol* is the trade name for the principal constituent in most of these formulas. It consists of citronellol and geraniol in the proportion of about two of the former to one of the latter. Nerol and terpeneless oil of rose are other constituents of importance. An indispensable ingredient is *phenyl-ethyl alcohol* $C_6H_5CH_2CH_2OH$ (*benzyl carbinol*), which contributes to the similarity of the odor. Other constituents the names of which appear in formulas for synthetic rose oil, intended to imitate one or the other of special types of rose are as follows: Alpha ionone, ethyl cinnamate, benzyl acetate, isobutyl acetate, isoeugenol, cinnamic aldehyde, citronellyl acetate, nonyl aldehyde and citral.

A rose oil is said to be distilled in Germany which contains 75 per cent. of phenyl-ethyl alcohol, which is present in only small proportions in ordinary rose oil, in which it ordinarily occurs as a benzoic ester or combined with phenylacetic acid. Hjort and Kaufman (*J. P. Ex. T.,* 1920, xv, 129) have shown this oil to be a powerful local anesthetic, but its instability is said to interfere with its practical usefulness.

A rose oil obtained in the yield of 0.015 per cent. by extraction of the petals with volatile solvents was found by F. Elze to have the following constants: Sp. gr. 0.9844 at 20° C., specific rotation +0.6°; acid value 3.15; ester value 2.9; acetylation value 317.5. Phenylethyl alcohol was the chief constituent of this oil which also contained geraniol, citronellol, nerol, and farnesol (*J. Soc. Chem. Ind.,* 1919, xxxix, 43A).

Oil of rhodium (*Oleum ligni Rhodii, Aspalathum*). This oil was attributed by Lewis to the *Convolvulus Scoparius* L. but according to Holmes (*Perfume and Essential Oil Record,* 1911, ii, p. 29) is the product of a species of *Genista,* either *G. canariensis* L. or *G. virgata* Link. It is used to adulterate oil of rose. Guaiac wood oil is also occasionally used for the same purpose. A factitious oil of rhodium is sometimes sold as a lure for rats and other animals. It is made from oil of copaiba flavored with a trace of oil of rose. The synthetic oil of rose has largely replaced that obtained by distillation.

Oil of rose may be added, as a grateful perfume, to various spirituous preparations for internal use, and to cerates and ointments. It is both too expensive and too powerful for most pharmaceutic purposes.

Off. Prep.—Unguentum Aquæ Rosæ, Br.

OLEUM ROSMARINI. U. S., Br.

OIL OF ROSEMARY Ol. Rosmar. [Rosemary Oil]

"The volatile oil distilled from the fresh flowering tops of *Rosmarinus officinalis* Linné (Fam. *Labiatæ*). Oil of Rosemary yields not less than 2.5 per cent. of esters calculated as bornyl acetate [$C_{10}H_{17}.C_2H_3O_2$], and not less than 10 per cent. of total borneol [$C_{10}H_{17}OH$] free and as esters." *U. S.* "Oil of Rosemary is the oil distilled from the flowering tops of Rosmarinus officinalis, *Linn.*" *Br.*

Oleum Rorismarini, Oleum Anthos; Huile volatile de Romarin, *Fr. Cod.;* Essence de Romarin, *Fr.;* Oleum Rosmarini, *P. G.;* Rosmarinöl, *G.;* Essenza di rosmarino, *It.;* Esencia de romero, *Sp.*

For description of the plant from which this oil is obtained see under *Rosemary,* Part II. The fresh leaves of rosemary yield, according to Baumé, 0.26 per cent. of volatile oil, but the percentage is rated much higher by others. Schimmel & Co. obtained by distillation from dry French rosemary flowers 1.4 per cent. of oil.

This oil is colorless, with an odor similar to that of the plant, though less agreeable. Its sp. gr. is said to be 0.911, but reduced to 0.8886 by rectification (0.894 to 0.912, *U. S.*). Buignet gives the sp. gr. of the rectified oil at 0.896, and states that it is moderately dextrogyrate. Its reaction is neutral. It is soluble in all proportions in alcohol of 0.830, but requires for solution at 17.7° C. forty parts of alcohol of 0.887. (Berzelius.)

Description and Physical Properties.—" A colorless or pale yellow liquid, having the characteristic odor of rosemary, and a camphoraceous taste.

" The Oil is soluble in 10 volumes of 80 per cent. alcohol, by volume. Specific gravity: 0.894 to 0.912 at 25° C. Optical rotation: varies from 0° to +15° in a 100 mm. tube at 25° C. Refractive index: 1.4660 to 1.4720 at 20° C. A solution of the recently distilled Oil in 80 per cent. alcohol (1 in 10) is neutral or only slightly acid to moistened litmus paper." *U. S.*

" Colorless or pale yellow. Odor that of rosemary; taste warm, camphoraceous. Specific gravity 0.895 to 0.920; *optical rotation* –2° to +15°; *refractive index* at 25° C. 1.463 to 1.473. Soluble in 1 part of *alcohol* (90 per cent.), and in 5 to 10 parts of a mixture of equal volumes of *alcohol* (90 per cent.) and *alcohol* (70 per cent.). Contains not less than 10 per cent. of total *alcohols,* calculated as borneol, $C_{10}H_{18}O$, and not less than 1.8 per cent. of *esters,* calculated as bornyl acetate, $C_{10}H_{17}C_2H_3O_2$." *Br.*

Kept in bottles imperfectly stoppered, it deposits a stearopten, sometimes amounting, according to Proust, to one-tenth of the oil.

Both Gladstone and Flückiger find that most of the oil consists of a hydrocarbon, which Schimmel & Co. (*Schim. Rep.,* Oct., 1889) identified as pinene, but there is a smaller fraction boiling at from 200° to 210° C., which at low temperatures deposits a camphor, identified as borneol. Weber examined oil of rosemary in Wallach's laboratory (*Ann. Ch. Ph.,* ccxxxviii, 89), and found that the fraction boiling between 176° and 182° C. contains cineol. The oil is therefore recognized at present as containing d-pinene, camphene, cineol, borneol (10–15 per cent.), and camphor. It is said to be sometimes adulterated with oil of turpentine, which may be detected by mixing the suspected liquid with an equal volume of pure alcohol, the oil of rosemary is dissolved, and that of turpentine left.

Assay for Esters.—" Proceed as directed for esters under *Oleum Menthæ Piperitæ,* using 10 cc. of Oil of Rosemary. Multiply the number of cc. of half-normal alcoholic potassium hydroxide consumed in the saponification of the Oil by 9.811, and divide the product by the weight of the Oil taken. The result shows the per cent. of esters, calculated as bornyl acetate.

" **Assay for Total Borneol.**—Proceed as directed for total menthol under *Oleum Menthæ Piperitæ,* using 10 cc. of Oil of Rosemary. Use the following formula in calculating the per cent. of total borneol.

Per cent. of total borneol =

$$\frac{A \times 7.710}{B - (A \times 0.021)} \times [1 - (E \times 0.0021)]$$

" *A* is the result obtained by subtracting the number of cc. of half-normal sulphuric acid required in the titration from the number of cc. of half-normal alcoholic potassium hydroxide originally taken, *B* is the weight of the acetylized oil taken, and *E* is the per cent. of esters calculated as bornyl acetate.

" Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Oil of rosemary is used, chiefly in combination with other drugs, as a carminative. It is also employed as an ingredient in rubefacient liniments. For a case of fatal poisoning, see *A. J. P.,* xxiii, 286.

Dose, three to six minims (0.2–0.4 cc.).

Off. Prep.—Spiritus Rosmarini, *Br.;* Tinctura Lavandulæ Composita, *U. S., Br.;* Spiritus Odoratus, *N. F.*

OLEUM SANTALI. U. S., Br.

OIL OF SANTAL Ol. Santal. [Oil of Sandalwood Santalwood Oil]

" The volatile oil distilled from the dried heart-wood of *Santalum album* Linné (Fam. *Santalaceæ*). Oil of Santal yields not less than 90 per cent. of alcohols calculated as santalol [$C_{15}H_{24}O$]." *U. S.* " Oil of Sandal Wood is the oil distilled from the wood of Santalum album, *Linn.*" *Br.*

Oleum Ligni Santali; Oleum Santali Flavi; Oil of Sandal Wood; Huile volatile (Essence) de Santal, *Fr.;* Oleum Santali, *P. G.;* Ostindisches Sandelholzöl, Santelöl, *G.;* Esencia de sandalo, *Sp.*

Sandalwood has been used medicinally since the middle of the 15th century.

Santalum album, or *yellow sandalwood,* is a small, evergreen, parasitic tree with opposite, elliptic-ovate or ovate-lanceolate leaves, and panicles of straw colored to blood red flowers, and black globular drupaceous fruits about the size of a cherry. It is indigenous to the mountainous districts of India and the Malay archipelago and has been cultivated in southern India for its wood and oil. For an interesting account of the cultivation of the plant see J. L. Pigot in *Schimmel's Report,* 1900.

Nearly all the sandalwood of commerce is obtained in Mysore, India. Here the tree is torn up and deprived of its bark and a portion of its sapwood. The trunks are then sawed into segments of about a metre, and trimmed, and the roots deprived of their bark.

A quantity of the oil is distilled in Mysore but most of the wood is exported to Great Britain and other countries directly from Mysore or Bombay, where it is used alike for the production of the volatile oil of santal and the manufacture of various articles.

Other varieties of sandalwood are collected in the Hawaiian Islands from *Santalum Freycinetianum* Gaud., and *S. pyrularium* A. Gray; in the Fiji Islands from *S. Freycinetianum* Gaud. (*S. Yasi* Seem.), in New Caledonia from *S. austrocaledonicum* Vieillb.; in Queensland from *Eremophila Mitchelli* Benth. (Fam. *Myoporaceæ*); and in East Africa from *Osyris tenuifolia* Engl.

Australian Sandalwood Oil.—Under this title there has appeared in commerce a variety of products, some of which seem to bear little relation to the true santal oil. From western Australia come two oils, one, also called *oil of amyris,* is obtained from the *Amyris balsamifera* L. (Fam. *Rutaceæ*) and does not contain any santalol, its most important constituent being a sesquiterpene alcohol called *amyrol,* $C_{15}H_{26}O$ (Vansoden, *Ph. Ztg.,* 1900, xlv, 878). It is used as an adulterant of santal oil from which it differs in its physical properties, especially in not being soluble in 70 per cent. alcohol. The second West Australian oil is from the *Fusanus spicatus* R. Br. (Fam. *Santalaceæ*); according to Rao and Sudborough (*J. Soc. Chem. Ind.,* 1923, xlii, 575A) it yields from 70 to 80 per cent. of santalol but will not meet the physical constants required by the British Pharmacopœia.

In Southern Australia a sandalwood is obtained from the *Santalum Preissianum* Miq. (*Fusanus acuminata* R. Br.), which yields an oil with a rose-like odor.

Venezuelan, or *West Indian Sandalwood* according to Holmes (*P. J.,* xii) is from the *Schimmelia oleifera* Holmes (*Amyris Balsamifera* L.).

Oil of santal is distilled in the United States, Germany, England, and India, the ordinary method of steam distillation being applied after the wood has been reduced to small particles by chipping or grinding. According to the Indian Pharmacopœia the yield of oil is about 2.5 per cent.

Description and Physical Properties.—"A pale yellow, somewhat viscid, oily liquid, having the characteristic odor and taste of sandalwood.

"The Oil is soluble in 5 volumes of 70 per cent. alcohol, by volume. Specific gravity: 0.965 to 0.980 at 25° C. Optical rotation: varies from –15° to –20° in a 100 mm. tube at 25° C. Refractive index: 1.5040 to 1.5080 at 20° C. A solution of the recently distilled Oil in 70 per cent. alcohol (1 in 5) is slightly acid to moistened blue litmus paper.

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

"Pale yellow or nearly colorless, somewhat viscid in consistence. Aromatic odor; taste unpleasant. Specific gravity 0.973 to 0.985; *optical rotation* –13° to –21°; *refractive index* at 25° C. 1.498 to 1.508. Soluble in 6 parts of *alcohol* (70 per cent.) at 20° C. Contains not less than 90 per cent. of total *alcohols,* calculated as santalol, $C_{15}H_{24}O$." *Br.*

Oil of santal is habitually adulterated, castor oil and other fixed oils being added, and on the continent of Europe by the volatile oil of cedar. Holmes states that the presence of more than 10 per cent. of the cedar oil can be recognized through the different solubilities of the oils in alcohol. (See *P. J.,* xvi, 820.) R. A. Cripps, after a thorough examination of the oils in the London market (see *P. J.,* 1892, 461), gives this test: "Two drops of the oil added to six drops of nitric acid, sp. gr. 1.5 on a white tile, should give a yellow to bright reddish-brown coloration, without any green, indigo, or violet tint at the edges during five minutes. For complete saponification in alcoholic solution, it requires not more than 1 per cent. of potassium hydrate." (See also *A. J. P.,* 1893, 20; *Schim. Rep.,* Oct. 1893; *P. J.,* 1895, 118; *West. Drug.,* 1897, 262.)

Assay.—"Proceed as directed for total menthol under *Oleum Menthæ Piperitæ,* page 262, using 10 cc. of Oil of Santal. Use the following formula in calculating the per cent. of santalol:

$$\text{Per cent. of santalol} = \frac{A \times 11.01}{B - (A \times 0.021)}$$

"*A* is the result obtained by subtracting the number of cc. of half-normal sulphuric acid required in the titration from the number of cc. of half-normal alcoholic potassium hydroxide originally taken, and *B* is the weight of the acetylized oil taken." *U. S.*

The following equations represent the reactions involved in the official assay:

$$C_{15}H_{25}OH + (C_2H_3O)_2O = C_{15}H_{25}OCOCH_3 + CH_3CO_2H$$

santalol + acetic anhydride = santalol acetate + acetic acid

$$C_{15}H_{25}O.COCH_3 + KOH = C_{15}H_{25}OH + CH_3CO_2K.$$

santalol acetate + potassium hydroxide = santalol + potassium acetate.

Constituents.—In the oil from *Santalum album* there exist two isomeric sesquiterpene alcohols having the formula $C_{15}H_{26}O$. One is bi-cyclic and is called *alpha-santalol,* the other is tri-cyclic and is called *beta-santalol.* The two *santalols* may be separated by careful fractional distillation and conversion of the fractions into the phthalates and subsequently into the strychnine salts of these compounds, which are finally separated by repeated recrystallizations until the melting point and rotatory power of each is constant. By the oxidation of the santalols, isomeric aldehydes are obtained called *santalals,* $C_{15}H_{24}O$.

Semmler regards nor-tricyclo-ecsantalane, $C_{10}H_{16}$, as the parent body of santalol.

Uses.—The oil of sandalwood is used largely as a perfume. In medicine its chief use is in *gonorrheal urethritis,* although it is sometimes employed in *chronic bronchitis* and *cystitis.* Its general antibacterial power is comparatively weak, but it has special relations towards certain micro-organisms; thus in the experiments of Jordan (*B. M. J.,* Sept. 13, 1913) twenty minims of oil of sandalwood three times a day had practically no effect on the growth of *B. coli* in the urine, but markedly retarded the multiplication of staphylococci. It was first recommended in medicine by Thomas B. Henderson who, however, is said to have used the oil of *S. myrtifolium.* Under the name of *arheol* a proprietary form of santalol is recognized by the *N. N. R.,* 1924. It is asserted to be less liable to upset the stomach than the whole oil. Numerous esters of this alcohol have been put on the market; these are described in Part II.

Dose, five to twenty minims (0.6–1.3 cc.), in emulsion, or in capsule, three or four times a day.

OLEUM SASSAFRAS. U. S.

OIL OF SASSAFRAS Ol. Sassaf. [Sassafras Oil]

"The volatile oil distilled from the root of *Sassafras variifolium* (Salisbury) O. Kuntze (Fam. *Lauraceæ*). If the oil has solidified in whole or in part, carefully warm it until liquefied, then thoroughly mix it before dispensing." *U. S.*

Huile volatile (Essence) de Sassafras, *Fr.;* Sassafrasöl, *G.;* Esencia de sasafras, *Sp.*

The proportion of oil yielded by the root of sassafras averages between 1 and 2 per cent.

Description and Physical Properties.—"A yellow or reddish-yellow liquid, having the characteristic odor and taste of sassafras.

"The Oil is soluble in 2 volumes of 90 per cent. alcohol, by volume. Specific gravity: 1.065 to 1.077 at 25° C. Optical rotation: varies from +3° to +4° in a 100 mm. tube at 25° C. Refractive index: 1.5250 to 1.5350 at 20° C. A solution of the recently distilled Oil in 90 per cent. alcohol (1 in 2) is neutral to moistened litmus paper. Oil of Sassafras meets the requirements of the test for ***heavy metals in volatile oils.***

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Variation in the sp. gr. of oil of sassafras may often arise through the congelation and separation of safrol, or through stratification. (LaWall and Pursel, *A. J. P.,* 1898, 340.)

The most complete investigation of sassafras oil is that made by Power and Kleber in 1896. (*Schim. Rep.,* April, 1896.) They find it to have the following composition: safrol about 80 per cent.; pinene and phellandrene, about 10 per cent.; dextrogyrate camphor about 6.8 per cent.; eugenol, about 0.5 per cent.; a high boiling portion, consisting of cadinene and residue, 3 per cent. They say that the hydrocarbon constituent of sassafras oil, to which Grimaux and Ruotte gave the name of *safrene,* is, as just stated, a mixture of pinene and phellandrene. Safrol is described in Part II.

Uses.—The oil of sassafras is much less irritant to mucous membranes than many of the other volatile oils, and is therefore of less service as a carminative. It is, however, a very powerful antiseptic. While chiefly esteemed at present for its pleasant flavor, it has a real therapeutic usefulness for its disinfectant properties. It has been highly praised by Peck (*J. A. M. A.,* 1899, xxxii, p. 6) for the disinfection of root canals in dentistry and is coming into considerable use in the treatment of nasal *catarrhs.* For the latter purpose it is generally employed dissolved in liquid petrolatum in strengths of about 1 per cent.

A teaspoonful of it produced in a young man vomiting, collapse, somewhat dilated pupils, and pronounced stupor. (*Cincinnati Lancet-Clinic,* Dec., 1888.) According to the experiments of A. Heffter (*Atti Dell' XI. Congres. Med. Internaz.,* iii, 1894), safrol is slowly absorbed from the alimentary canal, and escapes through the lungs unaltered and through the kidneys oxidized into *piperonalic acid.* When taken in sufficient dose, it quickly kills by a centric paralysis of respiration, preceded by great depression of the circulation, and when taken in smaller yet toxic amount, it causes death by widespread fatty degeneration of the heart, liver, kidneys, etc. Its isomer, *isosafrol,* is in warm-blooded animals much less active as a poison than is safrol, and is chiefly eliminated as *piperonalic acid.*

Dose, of oil of sassafras, two to six minims (0.12–0.4 cc.).

OLEUM SESAMI. N. F., Br.

SESAME OIL Ol. Sesam. [Teel Oil, Benne Oil]

"A fixed oil obtained from the seeds of one or more cultivated varieties of *Sesamum indicum* Linné (Fam. *Pedaliaceæ*)." *N. F.*

"Sesame Oil is the oil expressed from the seeds of Sesamum indicum, *Linn.*" *Br.*

Sesame oil is reputed by many pharmacists to resist rancidity better than other fixed oils of its class. For description of the plant yielding it see *Sesamum,* Part II.

Description and Physical Properties.—"Sesame Oil is a pale yellow, oily liquid, almost odorless, and having a bland taste. It is slightly soluble in alcohol, miscible with ether, chloroform, petroleum benzin, or carbon disulphide.

"Specific gravity: 0.916 to 0.921 at 25° C. Shake 1 cc. of the Oil for half a minute with a solution of 0.1 Gm. of sugar in 10 cc. of hydrochloric acid; the acid layer becomes bright red and changes to dark red on standing. Blue litmus paper previously moistened with alcohol is not more than slightly reddened by 2 cc. of the Oil (*free acid*). Mix 5 cc. of the Oil in a test tube with 5 cc. of a mixture of equal volumes of amyl alcohol and a 1 per cent. solution of sulphur in carbon disulphide, and immerse the test tube to one-third of its depth in a boiling saturated aqueous solution of sodium chloride: no reddish color develops in fifteen minutes (*cotton-seed oil*). Saponification value: not less than 188 nor more than 193. Iodine value: not less than 103 nor more than 112.

"Preserve it in well-closed containers." *N. F.*

"Pale yellow. Faint odor; taste bland. Specific gravity 0.921 to 0.924; *saponification value* 189 to 193; *iodine value* 103 to 114; *acid value* not more than 8; *refractive index* at 40° C. 1.4650 to 1.4675. When a mixture of 2 millilitres of the Oil and 1 millilitre of *hydrochloric acid* containing 1 per cent. of *refined sugar* is shaken for half a minute, and allowed to stand for five minutes, the acid layer becomes pink.

When 1 millilitre of the Oil and 15 millilitres of *N/1 alcoholic solution of potassium hydroxide* are boiled for twenty minutes in a flask provided with a reflux condenser, set aside for twenty-four hours at a temperature not exceeding 15.5° C., and afterwards heated on a water-bath for three minutes, the solution does not deposit crystals on standing for a further twenty-four hours (absence of arachis oil). When 2 millilitres of the Oil are mixed with 1 millilitre of *amylic alcohol* and 1 millilitre of a solution (1 in 100) of *precipitated sulphur* in *carbon disulphide,* and the mixture heated in a test-tube immersed in boiling *water,* no red color is developed within fifteen minutes (absence of cottonseed oil). In India, and in the Eastern, African, and North American Divisions of the Empire, Sesame Oil may be employed in making the official Liniments, Ointments, Plasters, and Soaps for which Olive Oil is directed to be used." *Br.*

The color reaction with sugar and hydrochloric acid was suggested as a distinguishing test from other oils by Schaedler (*A. Pharm.,* 1887).

Sesame oil is a non-drying oil. It contains about 75 per cent. of olein with smaller amounts of the glycerides of linoleic, palmitic, stearic, and myristic acids. Villavecchia and Fabris (*Zeit. für Ang. Chem.,* 1893, 505) found in addition: a higher alcohol of the formula $C_{25}H_{44}O$, fusing at 137° C., a finely crystallizing substance of the formula $C_{11}H_{12}O_3$, fusing at 123° C., which substance they name *sesamin,* and a thick uncrystallizable oil, non-nitrogenous, which is the cause of the cherry-red coloration which sesame oil shows with hydrochloric acid and sugar. Tocher (*P. J.,* 1893, 700), after analyzing *sesamin* and determining its molecular weight by Raoult's method in benzene and glacial acetic acid, maintains that its formula should be $C_{18}H_{18}O_5$. Tocher, as quoted by Lewkowitsch (*Chem. Anal. of Oils, Fats, and Waxes,* 2d ed., 389), also believes that the higher alcohol mentioned is cholesterol. *Sesamol* is a phenolic substance isolated by Kreis from sesame oil (*Chem. Ztg.,* 1903, p. 1030). Later investigations indicate that it does not occur in the oil in a free state but as a complex body from which sesamol is liberated by the addition of mineral acids.

Benne oil was known to the ancient Persians and Egyptians, and is esteemed by the modern Arabs and other people of the East both as food and as an external application to promote softness of the skin. In India it is generally used for cooking and anointing. It is laxative in large doses.

The name sesame oil is also sometimes applied to the oil from the cruciferous seed of *Camelina sativa.*

Sesame oil is used for pharmaceutical purposes.

Off. Prep.—Linimentum Ammoniæ, *N. F.;* Olea Infusa, *N. F.*

OLEUM SINAPIS VOLATILE. U. S., Br.

VOLATILE OIL OF MUSTARD Ol. Sinap. Vol. [Mustard Oil]

"The volatile oil obtained by maceration with water and subsequent distillation of the dried ripe seed (freed from fixed oil) of *Brassica nigra* (Linné) Koch or of *Brassica juncea* (Linné) Cosson (Fam. *Cruciferæ*), or prepared synthetically. The label must state the botanical source, or that it was made synthetically. Volatile Oil of Mustard yields not less than 93 per cent. of allyl isothiocyanate [C_3H_5NCS]. *Caution—Great care must be exercised in smelling this Oil. It should be tasted only when highly diluted." U. S.* "Volatile Oil of Mustard is the oil obtained by distillation from black mustard seeds, deprived of most of their fixed oil and macerated in water for several hours." *Br.*

Oleum Sinapis, *Br.* 1885; Oleum Sinapis Æthereum; Oil of Mustard; Huile volatile (Essence) de Moutarde, *Fr.;* Oleum Sinapis, *P. G.;* Senföl, Aetherisches Senföl, *G.;* Essenza di senape, *It.;* Esencia de mostaza negra, *Sp.*

After mustard seeds have been deprived of their fixed oil by hydraulic pressure, the cake—retaining its sinigrin and enzyme (see *Sinapis*)—when macerated in water gives rise to the characteristic volatile oil which may be collected by distillation. Most of the commercial supply of volatile oil of mustard, however, is of synthetic origin. According to Zeller mustard seeds yield from 0.33 to 0.63 of volatile oil.

Description and Physical Properties.—"A colorless or pale yellow, strongly refractive liquid, having a very pungent odor, and an acrid taste.

"Volatile Oil of Mustard is soluble in all proportions in alcohol, ether, and carbon disulphide. Specific gravity: 1.013 to 1.020 at 25° C. Optical rotation: inactive. Refractive index: 1.5268 to 1.5280 at 20° C. An alcoholic solution of the recently distilled oil is neutral to moistened litmus paper. The addition of 1 drop of ferric chloride T.S. to 1 cc. of the Oil, diluted with 5 volumes of alcohol, does not produce a blue coloration (*phenols*). The Oil distils completely between 148° and 154° C. Both the first and last 10 per cent. portions of the distillate have practically the same specific gravity as the original Oil (*alcohol, chloroform, petroleum or fatty oils*).

"Preserve in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

"Colorless or pale yellow. Intensely penetrating odor. Produces almost immediate vesication when applied to the skin. Specific gravity 1.014 to 1.025. Distils between 148° and 156° C. Contains in 100 millilitres not less than 92 grammes of allyl isothiocyanate, C_3H_5NCS, as determined by the following process." *Br.*

Assay.—"Dilute about 4 cc. of Volatile Oil of Mustard, accurately weighed, with sufficient alcohol to make exactly 100 cc. Transfer 5 cc. of this solution by means of a pipette to a 100 cc. measuring flask, and add 50 cc. of tenth-normal silver nitrate and 5 cc. of ammonia T.S. Connect the flask to a reflux condenser, and heat it on a bath of boiling water for one hour. Allow the liquid to cool to room temperature, disconnect the flask from the condenser, add sufficient distilled water to measure 100 cc., mix well, and filter. To 50 cc. of the filtrate, accurately measured, add about 5 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S., and titrate the excess of silver nitrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal silver nitrate corresponds to 0.004957 Gm. of allyl isothiocyanate." *U. S.*

"With *alcohol* (90 per cent.) prepare a solution containing 1 gramme of the Oil in 50 millilitres. To 5 millilitres of this solution in a 100 millilitre flask add 30 millilitres of *N/10 solution of silver nitrate* and 5 millilitres of *solution of ammonia.* Heat on a water-bath to 80° C. for thirty minutes, shaking frequently; cool to 15.5° C., make up to exactly 100 millilitres with *water,* and filter. To 50 millilitres of the filtrate add 4 millilitres of *nitric acid,* a few drops of *solution of ferric sulphate,* and sufficient *N/10 solution of ammonium thiocyanate* to produce a permanent red color. Not more than 5.7 millilitres of the latter reagent are required (presence of not less than 92 grammes of allyl isothiocyanate in 100 millilitres of the Oil)." *Br.*

Volatile oil of mustard consists chiefly of *allyl isosulphocyanate,* $CSNC_3H_5$ (*allyl isothiocyanate*); sometimes containing allyl cyanide and traces of carbon disulphide. This was first produced artificially by Berthelot and S. de Luca, by treating allyl iodide, C_3H_5I, with an alcoholic solution of potassium sulphocyanate. It is now extensively manufactured by this method. What first forms is allyl thiocyanate, which is not identical, but isomeric, with mustard oil (allyl isosulphocyanate). But if the sulphocyanate be heated to its boiling point 161° C., the thermometer sinks rapidly to 150° C., because of the change into the isosulphocyanate, or mustard oil. This change also takes place spontaneously at summer temperature. A small quantity of carbon disulphide seems always to be produced at the same time.

Ammonia converts the mustard oil into *thiosinamin* (see Part II), according to the reaction

$$CSNC_3H_5 + NH_3 = C_4H_8N_2S$$

The reaction is stated by Flückiger (*Pharm. Chem.,* 2d ed., 1888, p. 20) to be quantitative. Oil of mustard naturally contains about 0.56 per cent. of carbon disulphide. (*A. J. P.,* 1881, p. 572.)

Uses.—Oil of mustard is a powerful rubefacient, although liable to blister unless used with much caution. Diluted, either with alcohol or lard, it is used as a counter-irritant application in *sprains, rheumatism* and like conditions. It may be employed in strengths of from one to four per cent. According to Sollman (*J. P. Ex. T.,* 1918, xi, p. 229), the irritant effect of oil of mustard upon the skin is inverse to its solubility in the solvent employed; thus a 1 per cent. solution in olive oil caused practically no irritation, in dilute alcohol marked irritation, as an emulsion in mucilage still more.

The volatile oil of mustard has been employed as a substitute for the mustard plaster. For this purpose one part may be mixed with sixty parts of alcohol, and the mixture sprinkled, not too thickly, on muslin and covered with waxed paper. It acts speedily and efficiently.

The oil is too pungent and irritating to be given internally.

Off. Prep.—Linimentum Sinapis, *Br.;* Linimentum Sinapis Compositum, *N. F.;* Spiritus Sinapis, *N. F.;* Unguentum Sinapis, *N. F.*

OLEUM TEREBINTHINÆ. U. S.

OIL OF TURPENTINE Ol. Tereb. [Turpentine Oil "Spirits of Turpentine"]

"The volatile oil distilled from the oleoresin obtained from *Pinus palustris* Miller and other species of *Pinus* (Fam. *Pinaceæ*) which yield exclusively terpene oils." *U. S.*

Essence de Térébenthine, *Fr. Cod.;* Huile volatile de Térébenthine, *Fr.;* Oleum Terebinthinæ, *P. G.;* Terpentinöl, *G.;* Essenza di trementina, *It.;* Esencia de trementina, Aceite volatil de trementina, *Sp.*

This oil is commonly erroneously called *spirits of turpentine.* It is prepared by distillation from our common turpentine, though equally afforded by other varieties. It may be distilled either with or without water, but in the latter case a much higher temperature is required, and the product is liable to be empyreumatic. To obtain it quite pure it should be redistilled from a solution of potassium hydroxide. The turpentine of *Pinus palustris* is said to yield about 17 per cent. of oil, while that from *Pinus Pinaster* Ait. affords 25 per cent. and that from *Pinus sylvestris* L. 32 per cent.

Description and Physical Properties.—"A colorless liquid, having a characteristic odor and taste, both of which become stronger and less pleasant on aging or exposure to air. The Oil is soluble in 5 volumes of alcohol. Specific gravity: 0.854 to 0.868 at 25° C. Optical rotation: active, but variable. Refractive index: 1.4680 to 1.4780 at 20° C. An alcoholic solution of the recently distilled Oil (1 in 5) is neutral or only slightly acid to moistened litmus paper. Evaporate 5 cc. of the Oil in a small tared dish on a bath of boiling water: the weight of the residue does not exceed 0.1 Gm. (*petroleum, paraffin, or rosin oils*). Three drops of the Oil placed on white unsized paper and exposed to the air, evaporates without leaving a permanent stain (*fixed oils*). A 5 cc. portion of the Oils shaken with an equal volume of potassium hydroxide T.S. does not become darker than a light straw-yellow after standing twenty-four hours. A 5 cc. portion of the Oil shaken vigorously with an equal volume of hydrochloric acid in a glass-stoppered cylinder and allowed to stand for five minutes does not develop a color darker than a light straw yellow in either the acid or the oil layer. Place 100 cc. of Oil of Turpentine in a standard 100 cc. Engler flask, having the side tube 8 cm. above the top of the bulb, and distil the Oil at the rate of 2 drops per second: 90 per cent. of the Oil distils between 154° and 170° C., the temperature being read with the bulb of the thermometer opposite the side tube of the flask, and the top of the mercury column of the thermometer remaining within the neck of the flask. Place 20 cc. of fuming sulphuric acid in a graduated narrow-necked Babcock bottle, stopper, and place in an ice bath to cool, and then add slowly, drop by drop, from a pipette, 5 cc. of the Oil of Turpentine. Mix the acid and Oil, as added, by gently shaking or rotating the bottle, keeping the temperature at about 60° to 65° C. by continued immersion in the ice bath. When the mixture no longer becomes warm on shaking, agitate thoroughly by vigorously shaking for about one-half minute. Place the bottle in a water bath and heat at 60° to 65° C. for ten minutes, keeping the contents of the bottle thoroughly mixed by frequent vigorous shaking, not less than six times during the heating period. (*If the shaking at first is too prolonged and vigorous, there is danger of the escaping SO_2 forcing some of the mixture out of the neck of the bottle.*) Cool to room temperature, and fill the bottle with sulphuric acid (specific gravity about 1.83) until the oily layer rises into the graduated neck. Centrifuge for five minutes at 1200 revolutions per minute, or for fifteen minutes at 900 revolutions per minute, or allow to stand, lightly-stoppered, for twelve hours. The reddish or straw colored viscous layer which separates on top of the dark acid does not exceed 1 per cent. (0.05 cc.) of the volume of Oil taken (*mineral oil*). *Caution —The addition of Oil of Turpentine to the fuming sulphuric acid, must be made only drop by drop, because of the violence of the reaction.*

"Preserve in well-stoppered containers, in a cool place." *U. S.*

As found in commerce, it is always somewhat ozonized, but when perfectly pure it consists exclusively of carbon and hydrogen, and is composed of one or more terpenes, among which are pinene, which constitutes the major portion of the oil, and small amounts of camphene and fenchene with derivatives of pinene. (See p. 730.) The English or American oil (prepared from *Pinus palustris*) is composed of *dextro-pinene*, while the French oil (prepared from *Pinus Pinaster* Ait.) is composed of *lævo-pinene*. On the other hand, the Russian turpentine contains, in addition to pinene, *dipentene* (or *cinene*) and *sylvestrene*, and the Swedish turpentine contains pinene and sylvestrene. Both the American and the French oil of turpentine boil at about 156° C. On heating oil of turpentine to about 300° C. in a sealed tube for several hours it is converted into a polymer called *isoterebenthene*, $C_{20}H_{32}$, which is so oxidizable that it is converted into a viscid mass on exposure to the air for a few hours. This has a marked odor, resembling oil of lemon, and boils at 176° to 177° C. On treatment with a small portion of sulphuric acid, oil of turpentine yields an optically inactive liquid, which boils at 160° C. This is a mixture resolvable by repeated fractional distillation into *terebene*, $C_{10}H_{16}$, boiling at 150° C., *cymene*, $C_{10}H_{14}$, boiling at 175° C.; a small quantity of a camphor-like body, boiling at 200° C.; *colophene*, $C_{20}H_{32}$, boiling at 318° C., and a mixture of semi-solid products of higher boiling point. Oil of turpentine absorbs hydrochloric acid gas, forming with it two compounds, one a red dense liquid, the other a white crystalline substance resembling camphor, and hence called *artificial camphor*. Both are monohydrochlorides, $C_{10}H_{16}.HCl$, but the latter is much more stable, and can be purified by crystallization from alcohol or ether. When turpentine oil is left in contact with concentrated hydrochloric acid a dihydrochloride is formed, $C_{10}H_{16}.2HCl$. This forms rhombic plates, insoluble in water, and decomposed by boiling with alcoholic potash, with formation of *terpinol* $(C_{10}H_{16})_2.H_2O$. (Allen, *Com. Org. Anal.*, vol. ii, p. 51.) Nitric acid converts oil of turpentine into resin, and by long boiling into *terebic acid*, $C_7H_{10}O_4$. Turpentine oil and other terpenes unite with water to form crystals of *terpin hydrate*, $C_{10}H_{18}(OH)_2.H_2O$, which sublimes often from turpentine oil which has long stood in contact with water and has then been heated to water-bath temperature. These crystals are sometimes found in the natural oil also. The presence of alcohol with the water and turpentine oil facilitates their formation. Thus, a mixture of 1 part of nitric acid, 1 part of alcohol, and 4 parts of turpentine oil, spread out in flat dishes, will yield within a few days crystals amounting to 20 per cent. of the oil taken. If these crystals be fused at 116° C. they will lose water, and *terpin*, $C_{10}H_{18}(OH)_2$, will remain in crystalline needles, fusing at 104° C., and boiling at 258° C. If either of the hydrates just mentioned be boiled with sulphuric, phosphoric, or glacial acetic acid, *terpineol*, $C_{10}H_{17}OH$, will be formed along with hydrocarbons of the formula $C_{10}H_{16}$, such as terpinene, terpinolene, and dipentene. Terpineol is a thick, colorless, optically inactive liquid, with a pleasant hyacinthine odor and a bitter, feebly pungent taste. It is used extensively in perfumery. Baeyer (*B. Chem. G.*, xxvi, p. 826) has also prepared the methyl ether of terpineol. Oil of turpentine may be made to yield cymene identical with that existing in the oil of cumin and with that obtained by dehydrating camphor. (See *Cumin Seed*, in Part II; also see under *Olea Volatilia*.)

Exposed to the air the oil absorbs oxygen, becomes thicker and yellowish, and loses much of its activity, owing to the formation of resin. Hence the older Pharmacopœias directed the oil to be rectified by distilling it with about four measures of water. But the process is difficult, in consequence of the great inflammability of the vapor, and its rapid formation, which causes the liquid to boil over. In the present U. S. Pharmacopœia the oil is rectified by washing with sodium hydroxide, which saponifies the resin.

C. T. Kingzett has shown that the atmospheric oxidation of turpentine is accompanied by the formation of a body having the formula $C_{10}H_{14}O_4$, which he regards as *camphoric peroxide*. This substance, by the action of water, is converted into hydrogen peroxide and camphoric acid. The disinfectant known as *"sanitas"* is produced by passing air through Russian oil of turpentine in contact with warm water.

In this country the oil of turpentine is frequently adulterated with petroleum distillates. The adulteration is best detected by the treatment with sulphuric acid followed by steam distillation of the oil layer remaining above the sludge acid; this treatment with acid and after-distillation to be repeated if necessary. The sulphuric acid will thus completely polymerize the essential oil, leaving the paraffin hydrocarbons unaffected in the residual oily layer. A shorter and more readily executed test with sulphuric acid, though not so complete, is now given in the official test of the U. S. P. X.

Considerable quantities of a turpentine obtained by steam distillation of the so-called "lightwood," or resin saturated stumps and pieces of pine wood, have been offered in recent years. For an experimental study of this process and an account of the product see an article by Walker, Wiggins and Smith. (*Chemical Engineer,* Dec., 1905, p. 78.)

The presence of rosin oil in oil of turpentine may be detected by treating one drop of the distillate from 5 Gm. of the sample with sulphuric acid and acetic anhydride. A blue purple color indicates the presence of the impurity. Pine oil may be detected by the Heyfeld reaction, which consists of treating the sample with a few cc. of 10 per cent. sodium sulphate solution, followed by acidulation with sulphuric acid. A green-yellow fluid indicates pine oil, pure oil of turpentine remaining colorless. Hydrocarbons can best be detected by the bromine absorption test; 2.5 cc. of pure oil of turpentine decolorizing at least 25 cc. of standard bromine solution. (*Schweiz. Apoth. Ztg.,* 1915, 198.)

The several species of pine indigenous to California and the slopes of the Sierra Nevada appear to yield quite different products. Wenzell (*A. J. P.,* March, 1872) described, under the name of *abietene,* an oil distilled from the exudation of the *Pinus sabiniana* Dougl. (*Nut Pine* or *Digger Pine*). He found it to have a sp. gr. of 0.694, and to boil at 101° C. Sadtler (*A. J. P.,* April, 1879, p. 176) examined an oil of turpentine from California said to have been obtained from the *Pinus ponderosa* Dougl. (*Yellow-* or *Bull-Pine*), and found it to agree substantially with Wenzell's abietene. It was shown by Thorpe (*A. J. P.,* 1879, p. 293), and later confirmed by Schorlemmer, that the exudation of the California pine is almost pure *heptane,* C_7H_{16}, one of the chief constituents of American petroleum. It differs materially in its properties from the official oil.

Uses.—The oil of turpentine is locally irritant and feebly antiseptic. It is absorbed through the mucous membrane of the alimentary canal and apparently also of the respiratory tract, and is eliminated partly with the breath to which it imparts its own odor, and through the urine to which it gives an odor resembling that of violets. After the ingestion of large doses it produces a sense of warmth in the stomach, accelerates the circulation, and causes a feeling of exhilaration associated with more or less vertigo and a sense of fullness in the head. These symptoms are attended frequently with nausea and frequently, although not always, succeeded by brisk catharsis. When given in small doses frequently repeated it at first stimulates the kidneys, augmenting the secretion of urine, but if the administration is continued too long it produces painful irritation of the urinary vessels amounting at times to violent strangury and may cause inflammation of the kidney with scanty, albuminous, or even bloody urine. In some constitutions it produces, even when taken internally, an erythematous eruption of the skin. Apparently enough may be absorbed after the inhalation of its vapor to irritate the urinary organs and it is stated that seamen of vessels loaded with turpentine sometimes develop strangury and hematuria.

Most of the therapeutic uses of the oil of turpentine may be attributed to its local irritant influence; thus during its elimination through the mucous membrane of the lungs it acts as a stimulant expectorant and is a useful remedy in *chronic bronchitis.* In the same way it acts as a stimulant to the kidney and is occasionally used as a diuretic, although this employment has largely passed out of vogue. As a carminative in *flatulent colic* it is one of the most valuable remedies we possess. It is sometimes of service for its local stimulant action for *chronic diarrheas* or *dysentery.* In *typhoid fever* it is useful not merely in tympanitic states for its carminative effects, but appears to have a direct influence upon the disease itself. According to the observations of Omelchenko (*B. G. T.,* 1891), while it is very feeble in its general antibacterial properties it has a special toxicity for the typhoid bacillus and this organism will not grow in an atmosphere saturated with turpentine vapor.

Oil of turpentine has been used for many years in the treatment of *hemoptysis.* Of its mode of action we have no knowledge, but there is considerable clinical evidence as to its power to check bleeding; Smith (*B. M. J.,* 1908, i,

p. 1218) has even recommended it in *purpura hemorrhagica.* Among other conditions in which it has been from time to time recommended with more or less reasonableness, are *helminthiasis, leucorrhea, chronic rheumatism, amenorrhea,* and *puerperal fever.*

For ordinary purposes the dose of the rectified oil is from 5 to 10 minims (0.3–0.6 cc.) repeated every two to six hours as may be necessary. As a remedy against the *tapeworm* the dose is from one-half to one fluidounce (15–30 cc.), followed in half an hour by castor oil; the safety of these large doses is dependent upon the catharsis sweeping out the bowel before the turpentine can be absorbed. It is best administered in the form of an emulsion, although it is frequently given by dropping into a teaspoonful of sugar. The use of gelatin-coated capsules is not to be recommended because as soon as the gelatin dissolves in the stomach the undiluted oil comes in contact with the gastric mucosa and is liable to produce an undue degree of irritation.

In the form of an enema the oil of turpentine is highly useful in obstinate *constipation, tympanitis,* and *seat worms.* From one-half to two fluidounces (15–60 cc.) may be added to a pint of warm soapsuds.

Externally it is an excellent rubefacient and is widely employed in the form of liniments in various rheumatic affections as *lumbago, arthritis, neuralgias,* and the like. For this purpose it should be diluted with from one to three parts of cottonseed or other bland oil. In the form of turpentine stupe it is advantageously employed as a counter-irritant in various deep seated inflammations, especially of the abdomen. The turpentine stupe is made as follows: a piece of flannel is wrung out in hot water and then either sprinkled with or dipped in previously warmed turpentine, quickly wrung out and applied to the part. It was also formerly employed as a local application to *burns* in which it was supposed to allay the pain and promote healing. For this purpose it was usually mixed with the rosin cerate so as to form a liniment capable of being spread upon linen (see *Linimentum Terebinthinæ*).

The following is the formula adopted many years ago by the Philadelphia College of Pharmacy for the rubefacient liniment known as *British Oil,* which is still in use in some parts of the country as a popular remedy. Oil of Turpentine, Linseed Oil, of each, 8 fl. oz., Oil of Amber, Oil of Juniper, of each, 4 fl. oz., Barbados Petroleum 3 fl. oz., Crude American Petroleum 1 fl. oz.

Oil of turpentine has likewise been recommended as a local application in parasitic *skin diseases,* especially *pediculus capitis.* The inhalation of its vapors has been employed in *chronic bronchitis* and has been especially recommended by Skoda in *gangrene of the lungs.*

For internal use the rectified oil should be used. (See *Oleum Terebinthinæ Rectificatum.*)

OLEUM TEREBINTHINÆ RECTIFICATUM. U. S., Br.

RECTIFIED OIL OF TURPENTINE Ol. Tereb. Rect.
[Rectified Turpentine Oil]

"Rectified Oil of Turpentine is the oil distilled from the oleo-resin (turpentine) obtained from various species of Pinus, and rectified." *Br.*

Essence de Térébenthine purifiée, *Fr.;* Oleum Terebinthinæ Rectificatum, *P. G.;* Gereinigtes Terpentinöl, *G.*

"Oil of Turpentine, a convenient quantity. Solution of Sodium Hydroxide, an equal quantity. Mix the two liquids thoroughly in a suitable still provided with a well-cooled condenser. Recover about three-fourths of the Oil by distillation, and separate the clear oil from the water. Dry the Oil by shaking with anhydrous calcium chloride or anhydrous sodium sulphate, and filter.

"NOTE.—Rectified Oil of Turpentine is to be dispensed when Oil of Turpentine is required for internal use. Oil that has become turbid should not be dispensed." *U. S.*

When oil of turpentine is distilled in contact with sodium hydroxide solution, the distillate comes over purified and freed from the decomposition products which give the commercial oil the disagreeable odor and taste which are inseparable by ordinary distillation without alkali; hence this rectified oil is much preferable for internal administration. It has in other respects the same properties as Oleum Terebinthinæ.

Description and Physical Properties.—"A colorless liquid which conforms to the properties and tests under *Oleum Terebinthinæ,* specific gravity and non-volatile residue excepted. Specific gravity: 0.853 to 0.862 at 25° C. Evaporate 5 cc. of Rectified Oil of Turpentine rapidly in a tared dish on a bath of boiling water: the weight of the residue does not exceed 0.015 Gm.

"Preserve in well-stoppered, amber-colored bottles in a cool place protected from light." *U. S.*

"A colorless, limpid liquid. Characteristic odor; taste pungent, somewhat bitter. Specific gravity 0.860 to 0.870; *refractive index* at 25° C. 1.465 to 1.480. Distils almost entirely between 156° and 180° C., leaving no appreciable residue." *Br.*

For uses see under *Oleum Terebinthinæ.*

Dose, five to ten minims (0.3–0.6 cc.).

Off. Prep.—Emulsum Olei Terebinthinæ, *U. S.;* Linimentum Terebinthinæ, *Br.;* Linimentum Terebinthinæ Aceticum, *Br.*

OLEUM THEOBROMATIS. U. S., Br.

OIL OF THEOBROMA Ol. Theobrom. [Cacao Butter]

"The fat obtained from the roasted seeds of *Theobroma Cacao* Linné (Fam. *Sterculiaceæ*)." *U. S.* "Oil of Theobroma is a solid fat expressed from the seeds of Theobroma Cacao, *Linn.*" *Br.*

Oleum Theobromæ, *U. S.* 1880; Butter of Cacao; Cocoa butter (improperly); Beurre de Cacao, *Fr. Cod.*; Oleum concretum e semine Theobromæ Cacao, *Fr.*; Oleum Cacao, *P. G.*; Kakaobutter, *G.*; Manteca de coco, Aceite de coco, *Sp.*

For description of this tree see under *Cacao Præparata.*

Oil of theobroma is extracted either by expression, decoction, or the action of a solvent. Soubeiran recommends that the seeds, previously ground, be mixed with one-tenth of their weight of water and then pressed between hot plates of tinned iron. It is advisable that the heat should not exceed that of boiling water, and even a lower heat will answer. When the method of decoction is used, the cacao should be slightly roasted before boiling. As a solvent, carbon disulphide has been found to answer well, as recommended in the preparation of the expressed oil of nutmeg. (See *Oleum Myristicæ.*) Upon the whole, the method of expression is perhaps preferable. The presence of water in the ground seeds is said greatly to facilitate the process. The commercial supply is largely a by-product in the manufacture of cocoa. It occurs usually in the shape of oblong cakes, weighing about half a pound each.

Description and Physical Properties.—"A yellowish-white solid, having a faint, agreeable odor, and a bland, chocolate-like taste. It is usually brittle at temperatures below 25° C. Oil of Theobroma is slightly soluble in alcohol; soluble in boiling dehydrated alcohol; freely soluble in ether, chloroform, petroleum benzin, and in benzene.

"Specific gravity: about 0.973 at 25° C. It melts between 30° and 35° C. Refractive index: 1.4537 to 1.4578 at 40° C. Dissolve 1 Gm. of Oil of Theobroma in 3 cc. of ether in a test tube at a temperature of 17° C., and immerse the tube in water having the temperature of melting ice: the liquid does not become turbid or deposit white flakes in less than three minutes. After congealing, raise the temperature to 15° C.: a clear liquid is gradually formed (*wax, stearin,* or *tallow*). Saponification value: not less than 188 and not more than 195. Iodine value: not less than 33 and not more than 38." *U. S.*

"A yellowish-white solid, breaking with a smooth fracture. Odor resembling that of cocoa; taste bland, agreeable. Somewhat brittle at ordinary temperatures, but softening at 25° C. Specific gravity 0.990 to 0.998; melting point 30° to 33° C.; *saponification value* 188 to 195; *iodine value* 35.5 to 37.5; *acid value* not more than 2.0; *refractive index* at 40° C. 1.4565 to 1.4575. In ascertaining the melting point and specific gravity, seventy-two hours should be allowed to elapse between the time of melting and the time of determining the constants. When 1 gramme is dissolved at 17° C. in 3 millilitres of *ether* in a test-tube, and the tube placed in *water* at 0° C., the solution neither becomes turbid nor deposits a granular or flaky mass in less than three minutes; and if, after congealing, it is exposed to a temperature of 15.5° C., a clear solution is gradually formed (absence of certain other fats)." *Br.*

Cacao butter consists chiefly of the glycerides of stearic, palmitic, and lauric acids, with small quantities of the glycerides of arachidic, linoleic, formic, acetic, and butyric acids. The percentage of stearic acid obtainable is from 39.9 to 40.6. Kingzett believes it to contain in addition a peculiar acid which he calls *theobromic,* and to which he gives the formula $C_{64}H_{128}O_2$, but his results have not been confirmed by subsequent investigators. From its large proportion of stearin, it is one of the best fats for the preparation of stearic acid. It is said to be frequently adulterated with animal fats, which are excluded by the official tests.

Uses.—Butter of cacao is used as an ingredient in cosmetic ointments, and in pharmacy for coating pills and preparing suppositories. For the last purpose it is well adapted by its blandness, and the fact that although liquefying at a temperature below that of the body, it is of firm consistence at 20° C. It is also valuable for the reason that easily decomposable substances like silver nitrate, potassium permanganate, etc., may be incorporated in it without material change and it is therefore valuable as an excipient. It has the emollient properties of the fats and is used to soften and protect *chapped hands* or *lips.*

OLEUM THYMI. N. F.

OIL OF THYME Ol. Thymi. [Thyme Oil]

"A volatile oil distilled from the flowering plant of *Thymus vulgaris* Linné (Fam. *Labiatæ*), and containing not less than 20 per cent., by volume, of phenols." *N. F.*

Huile volatile de Thym, *Fr. Cod.*; Essence de Thym, *Fr.*; Oleum Thymi, *P. G.*; Thymianöl, *G.*; Esencia de tomillo, *Sp.*

In the south of France thyme grows wild in great abundance, and is largely collected for distillation. The oil is taken from France to England, and thence reaches this country under the name of *oil of origanum,* having, probably from its greater cheapness, been substituted for the latter. (See Part II.)

Thymus vulgaris is a common plant, indigenous to Southern Europe, and cultivated in our gardens. It possesses a subcampanulate two-lipped calyx, villous in the throat; corolla limb two-lipped, the upper erect and emarginate, the lower spreading, three-cleft. It is a low undershrub, procumbent at the base, with ovate-linear, revolute leaves, the flowers occurring in a whorled spike. The herbaceous portion, which should be gathered when the plant is in flower, has a peculiar, strong, aromatic, agreeable odor, not lost by drying, and a pungent, aromatic camphoraceous taste. The dried herb yields on distillation about 1 or 2 per cent. of volatile oil.

The oil, as prepared in Southern France, is, after one distillation, of a reddish-brown color, and called the *red oil,* but when again distilled is colorless, and in this condition is distinguished as the *white oil;* this colorless oil, however, usually reddens again on keeping.

Description and Physical Properties.—"Oil of Thyme is a colorless or red liquid, having a characteristic odor and taste. It is soluble in 2 volumes of 80 per cent. alcohol.

"Specific gravity: 0.894 to 0.930 at 25° C. It is slightly lævorotatory. Shake 1 cc. of the Oil with 10 cc. of hot distilled water, and, after cooling, pass the aqueous layer through a wetted filter; the filtrate does not assume a blue or violet color upon the addition of a drop of ferric chloride T.S.

"**Assay.**—Introduce 75 cc. of sodium hydroxide T.S. into a flask with a long graduated neck (cassia flask), add 10 cc. of the Oil to be assayed, stopper the flask tightly, shake the mixture thoroughly, and set it aside for from twelve to twenty-four hours. Then add sufficient sodium hydroxide T.S. to raise the lower limit of the oily layer within the graduated portion of the neck of the flask, and, after the alkaline solution has become clear, adjust it to the temperature at which it was measured, and note the volume of the residual liquid. This measures no more than 8 cc., indicating the presence of not less than 20 per cent., by volume, of phenols.

"Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." *N. F.*

The more volatile portion, that coming over below 180° C. in distillation, is a mixture of cymene and pinene. The less volatile and most valuable portion is chiefly thymol, a white crystalline solid, which constitutes from 20 to 30 per cent. of the oil. (See *Thymol.*) Carvacrol is also present, at times replacing part or all of the thymol, and in addition linalool and bornyl acetate have been found in small amount. (See *Proc. A. Ph. A.*, 1897, 637.)

The *Spanish oil of thyme* according to Dorronsow (*Ph. Era,* 1921, liv, p. 102) is obtained not only from the official species but also from the *T. Zygis* L., *T. Liemalis* Lg. and *Corydothymus capitatus* Robb. It differs in its composition from the official oil in containing considerable amounts of carvacrol.

The oil is commonly adulterated with the oil of turpentine, the *white oils* being especially impure. The presence of oil of turpentine, according to Duyk (*J. P. A.*, 1899, 41), is due to the fact that the French peasants place in the body of the still as a foundation for the herbs a layer of pine and fir branches.

Oil of thyme has been largely replaced in medicine by thymol. According to Camperdon, in doses of from three to fifteen grains (0.2–1.0 Gm.), oil of thyme causes mental excitement, and is a valuable diffusible stimulant in *collapse.* It is powerfully germicidal. (See *Thymol.*)

Dose, one to five minims (0.06–0.3 cc.).

Off. Prep.—Liquor Antisepticus, *N. F.;* Mistura Oleo-Balsamica, *N. F.;* Oleum Hyoscyami Compositum, *N. F.*

OLEUM TIGLII. U. S. (Br.)

CROTON OIL. Ol. Tiglii

"The fixed oil expressed from the seeds of *Croton Tiglium* Linné (Fam. *Euphorbiaceæ*). *Caution—It must be handled carefully as it causes pustular eruptions when applied to the skin.*" *U. S.* "Croton Oil is the oil expressed from the seeds of Croton Tiglium, *Linn.*" *Br.*

Oleum Crotonis, *Br.;* Huile de Croton Tiglium, *Fr. Cod.;* Huile de Graines de Tilly, *Fr.;* Oleum Crotonis, *P. G.;* Krotonöl, *G.;* Olio di crotontiglio, *It.;* Aceite de croton tiglio, Aceite de grano tiglio, *Sp.*

Croton Tiglium Willd. is a small tree or shrub, with a few spreading branches, bearing alternate petiolate leaves, which are ovate, acuminate, serrate, smooth, of a metallic green to bronze and orange or variegated color on the upper surface, paler beneath. The flowers are in erect terminal racemes, scarcely as long as the leaf—the lower being pistillate, the upper staminate—with straw-colored petals. The fruit is a smooth capsule, about the size of a filbert, with three cells, each containing a single seed.

The tree is a native of Hindostan, Ceylon, and other parts of India. It is pervaded by an acrid purgative principle, probably analogous to that found in other plants belonging to the family of *Euphorbiaceæ.* Rumphius says that the root is employed in Amboyna, in the dose of a few grains, as a drastic purge in dropsy, and, according to the same author, the leaves are so acrid that when chewed and swallowed they excite inflammation in the lips, mouth, and throat, and along the whole course of the alimentary canal. The wood is said in small doses to be diaphoretic, in larger, purgative and emetic. But the seeds are the most active part. These have been long used in India as a powerful purgative, and were employed so early as 1630 in Europe, under the names of *grana Molucca* and *grana tiglia.* But in consequence of their violent effects they fell into neglect, and had ceased to be ranked among medicines, when, at a comparatively recent period, attention was again called to them by the writings of some English physicians in India. They are now imported for their oil, which is the only official product of the plant.

It is probable that most if not all of the *Crotons* are purgatives. The oil of the Mexican *Croton morifolius* Willd. is said to be mildly purgative in doses of two or three minims (0.12–0.2 cc.). In India, under the name of *Kowli seeds* (*Kuli seeds*), are used certain beans, which have been referred by authorities to *Croton oblongifolius* Roxb., and also to the *C. persimilis* Müll.-Arg. (See *Ph. Rev.*, Oct., 1896.) Kowli seeds reach a length of 2.1 cm., a breadth of 1.2 cm., a thickness of 0.8 cm., ovate, having pointed ends with a marked caruncle. The outer side shows the grayish-brown crusty seed coat with irregular rough longitudinal stripes; the cross-section shows a large endosperm, in the middle the embryo of considerable size with flat cotyledons. Besides the fatty oil and protoplasm, the cells of the endosperm show longitudinally very large aleurone grains, which contain a considerable number of small globoids and badly formed crystalloids. Cash and Dilling (*J. P. Ex. T.*, 1914, v, p. 235) have also found a purgative oil in the seeds of the *Croton Elliottii* Chapm. which grows in British East Africa.

The seeds of the *C. Tiglium* resemble castor beans in general structure. They are oblong, rounded at the extremities, with two faces, the dorsal considerably more convex than the ventral, separated from each other by longitudinal ridges, and each divided by a similar longitudinal ridge, so that the whole seed presents an irregular quadrangular figure. Sometimes their ventral surface is flat, with a longitudinal groove, owing to the presence of only two seeds in the capsule, the groove being produced by the central column or axis. The shell is covered with a soft, yellowish-brown epidermis, beneath which the surface is black and smooth, and, as the epidermis is often partially removed by friction during their carriage, the seeds as they come to us are frequently mottled, and sometimes nearly black. The kernel or endosperm is yellowish-brown, and abounds in oil.

The commercial supplies of croton seeds come to the United States chiefly from Colombo, Ceylon. Smaller amounts are obtained from Bombay and London. In India the seeds are prepared for use by submitting them to slight torrefaction, by which the shell is rendered more easily separable. In the dose of one or two grains (0.065 or 0.13 Gm.) the kernel purges severely.

Both the U. S. and Br. direct the oil be obtained by expression from the seeds, but commercially it is also separated by decoction in water, or by the action of ether, or carbon disulphide, which dissolves the oil and leaves it behind when evaporated. It is open to question whether the oils obtained by expression and extraction are of exactly the same composition.

The seeds consist of 64 per cent. of kernel and 36 of envelope. From the seeds imported into England, about 22 per cent. of oil is obtained by simple expression. Guibourt, by his process, obtained 52 per cent. from the kernels, equivalent to about 35 per cent. from the seeds. They contain also a toxic mixture of globulin and albumose, analogous to ricin (see *Oleum Ricinus*), which is known as crotin.

Crotin is described as a yellowish powder, yielding about 21 per cent. of ash, soluble in water, and possessed of such active poisonous properties that the subcutaneous lethal dose for the rabbit is from 0.05 to 0.08 Gm. per kilo. It attacks the blood corpuscles as well as the central nervous system, and, indeed, probably affects all protoplasm. (*On Some Toxic Albumins,* Upsala, 1897.)

Croton oil, as found in commerce, varies greatly in color, from a pale yellow to a dark reddish-brown. That imported from India is usually pale, that expressed in Europe dark, like the deepest-colored sherry. Its consistence is rather viscid, and is increased by time. Its odor is faint, but peculiar, its taste hot and acrid leaving in the mouth a disagreeable sensation which continues for many hours.

Description and Physical Properties.—"A pale yellow or brownish-yellow, somewhat viscid and slightly fluorescent liquid, having a slight, characteristic odor. Croton Oil is slightly soluble in alcohol, the solubility increasing with age; freely soluble in ether, chloroform, and in fixed or volatile oils.

"When gently heated with twice its volume of dehydrated alcohol, it forms a clear solution from which the Croton Oil separates, either partially or completely, on cooling. It is acid to litmus paper previously moistened with alcohol. Specific gravity: 0.935 to 0.950 at 25° C.

"Add 1 cc. of fuming nitric acid and 1 cc. of distilled water to 2 cc. of the Oil, and shake the mixture vigorously for a few minutes: it does not solidify either completely or partially after standing for twenty-four hours (*foreign oils*). Saponification value: not less than 200 and not more than 215. Iodine value: not less than 104 and not more than 110.

"Preserve in small, well-stoppered bottles, protected from light." *U. S.*

"Brownish-yellow to dark reddish-brown; viscid, slightly fluorescent. Disagreeable odor; when cautiously tasted, acrid. Blisters the skin and mucous membrane. Specific gravity 0.940 to 0.960; *saponification value* 210 to 215; *iodine value* 102 to 106. Freely soluble in *ether* and in *chloroform*. Miscible with half its volume of *absolute alcohol*. Thickens slightly but does not solidify, either completely or partially, when vigorously shaken with half its volume of *fuming nitric acid* and the same proportion of *water* (absence of other non-drying oils)." *Br.*

Croton oil may be detected when present in admixture with other oils by the following reaction: The sample of oil is shaken with twice its volume of dehydrated alcohol; the clear solution is superimposed upon a highly concentrated solution of potassium hydroxide in a test tube, which is then carefully warmed for thirty minutes on a water bath and then examined. If croton oil is present, an intense reddish-brown or reddish-violet ring forms at the junction of the two liquids. (*J. P. C.*, 1916, xiv, 38.)

Croton oil has been often adulterated with other fixed oils, which having a different saponification and iodine number can usually be detected by those tests. There is reason to believe that the oils of allied plants such as *Jatropha Curcas* (see *Barbados Nuts,* Part II) or other species of *Croton* are sometimes substituted for it.

Constituents.—Croton oil consists chiefly of the glycerides of stearic, palmitic, myristic, lauric, and oleic acids. There are also present, in the form of glycerin ethers, the more volatile acids, as formic, acetic, isobutyric, and isovalerianic acids. The volatile part of the acid yielded by croton oil contains, moreover, an acid of the oleic series, named by Geuther and Frölich *tiglic* or *tiglinic acid,* $C_5H_8O_2$. It is isomeric with angelic acid, but the melting points (angelic acid 45° C., tiglic acid 64° C.) and the boiling points (angelic acid 185° C., tiglic acid 198.5° C.) differ. *Crotonic acid,* $C_4H_6O_2$, was thought by Schlippe to be present, but later investigation does not confirm the statement. *Crotonol,* announced by Schlippe as the vesicating principle of the oil, has likewise been found only by the discoverer.

In 1873 Buchheim found in croton oil an alcohol-soluble, oily substance which he called *crotonoleic acid* and to which he attributed the cathartic powers of the oil. (For method of its preparation see *U. S. D.,* 20th ed., p. 801.) Dunstan and Boole (*Proc. Royal Soc. of London,* 1895, lxiii) state that this is a mixture of inert oily acids and that the true active ingredient is a resinous substance for which they suggest the name of *croton resin.* This conclusion has been confirmed by Boehm (*A. E. P. P.,* 1915, lxxix, p. 138); by repeated extraction with methyl alcohol and treating the extract with barium hydroxide to get rid of the fatty acids, he obtained an intensely irritant and poisonous resin which was optically active. He suggests that a polarimetric examination of the oil would afford a useful criterion for its valuation.

Uses.—Croton oil is a powerful drastic purgative, in large doses apt to excite vomiting and severe griping pains, and capable, if immoderately taken, of producing fatal effects. It acts with great rapidity, frequently evacuating the bowels in less than an hour, and generally exciting a rumbling sensation in half that period. It possesses also great advantage in the minuteness of the dose, on account of which it may frequently be given when we should fail with more bulky medicines, as in *mania, coma,* and the cases of children. A drop placed on the tongue of a comatose patient will generally operate. Though long used in India, and known for two centuries to the Dutch physicians, it did not attract general notice till about 1820, when it was introduced into England by Conwell. It is employed in cases of *obstinate constipation,* in which other cathartics have failed or when violent or speedy purging is demanded. The seeds are said to have been used successfully in India, in *amenorrhea.* Applied externally, the oil produces inflammation of the skin, attended with pustular eruption, and has been used as a counter-irritant in *rheumatism, gout, neuralgia, bronchitis* and other inflammations. It should be diluted with three parts of olive oil, soap liniment, oil of turpentine, or other convenient vehicle, and applied as a liniment twice or oftener in twenty-four hours. It has been said that four drops, used externally by friction, will produce a purgative effect, but this is denied by Barlai of Tuscany, who states that it is only when the oil is applied to the skin divested of the cuticle that it will operate upon the bowels.

The oil is most conveniently administered in the form of pill. A safe and convenient plan is to make two drops into four pills with a crumb of bread, and to give one every hour until they operate. The oil may also be given in emulsion.

According to Kobert crotonoleic acid is a very active irritant poison, much more harsh and severe in its influence than croton oil itself. He maintains, therefore, that old, acid croton oil must be more irritant than the fresher and nearly neutral oil, and asserts that the neutral oil should always be preferred in practice, and that the acid oil should be rejected.

Dose, one-half to two minims (0.03–0.12 cc.).

OLIVERI CORTEX. Br.

OLIVER'S BARK [Black Sassafras]

"Oliver's Bark is the dried bark of Cinnamomum Oliveri, *Bailey.*" *Br.*

The genus *Cinnamomum* comprises some fifty-four species which are mostly tropical or subtropical evergreen shrubs or trees. They are mostly aromatic and comprise two principal groups: The one yielding camphor, and the other aromatic cinnamon-like barks. The tree which furnishes oliver bark is *Cinnamomum Oliveri* Bailey (Fam. *Lauraceæ*). It is indigenous to New South Wales and Queensland, where it is sometimes called *Black Sassafras.* It is much of the same habit as the trees yielding cinnamon and the bark is used as a substitute for this spice in the Australian Colonies.

"In flat pieces usually about twenty centimetres long, four centimetres wide and one centimetre thick. Cork greyish-brown, very warty. Inner surface umber-brown, satiny. Fracture short, slightly fibrous. In transverse section, umber-brown, a pale line separating the cork from the inner tissues. Aromatic odor; taste aromatic, bitter, camphoraceous." *Br.*

Oliver bark yields a yellow volatile oil which contains safrol, eugenol, cineol and cinnamic aldehyde. It also contains tannin. It is used as a substitute for cinnamon.

Off. Prep.—Tinctura Oliveri Corticis, *Br.*

OPIUM. U. S., Br.

OPIUM

"Opium is the air-dried, milky exudation obtained by incising the unripe capsules of *Papaver somniferum* Linné or its variety *album* De Candolle (Fam. *Papaveraceæ*). Opium in its normal, moist condition yields not less than 9.5 per cent. of anhydrous morphine." *U. S.* "Opium is the juice obtained by incision from the unripe capsules of Papaver somniferum, *Linn.*, inspissated by spontaneous evaporation. Any suitable variety of opium may be employed as a source of Tincture of Opium and Extract of Opium, provided that when dry it contains not less than 7.5 per cent. of anhydrous morphine; but, when used for official purposes other than the preparation of the alkaloids or their salts, opium must be of such a strength that when dried, and powdered, the resulting powder dried at 60° C. yields not less than 9.5 per cent., and not more than 10.5 per cent., of anhydrous morphine. Opium yielding when dried more than 10 per cent. of anhydrous morphine must be diluted to that percentage either with powdered Milk Sugar or with any opium containing when dried between 7.5 and 10 per cent. of anhydrous morphine." *Br.*

Lachryma Papaveris, Meconium, Succus Thebaicus, Thebaica; Opium, *Fr. Cod.;* Opium, *P. G.;* Mohnsaft, *G.;* Oppio, *It.;* Opio, *Sp.;* Affioni, *Turk.;* Ufyoon, *Arab.;* Sheerikhaskash, *Pers.;* Ufeem, *Hindost.*

Opium is generally believed to be derived exclusively from *Papaver somniferum,* though every species of poppy is capable of yielding it to a greater or less extent. The United States, British and French Pharmacopœias recognize only the first mentioned species and its varieties.

Papaver somniferum L., or *Opium Poppy,* is an annual, glabrous and glaucous herb up to four feet in height, indigenous to Asia but cultivated in many tropical, subtropical and temperate countries. It possesses large, oblong, sinuate to dentate-serrate leaves, clasping at the base, and long peduncles, with nodding buds that expand into erect flowers which while usually purplish are sometimes white, pink or red in color. Each flower consists of a receptacle bearing two green sepals, four colored petals, numerous stamens and a syncarpous pistil composed of a globose ovary showing many projecting parietal placentæ bearing the ovules and a compound, radiate, sessile stigma. The fruits are globose capsules each with an 8–12 rayed sessile stigma and containing numerous small oily seeds. There are several varieties of this species, of which the two most prominent are distinguished by the titles of the white and the black poppy, derived from the color of their seeds. The *Papaver somniferum* var. *album* DC., *white poppy,* is annual, with a cylindrical smooth, erect, glaucous, often branching stem, usually rising two or three feet in height, but sometimes five or even six feet in favorable situations. The leaves are large, variously lobed and toothed, and alternately disposed on the stem, which they closely embrace. The flowers are terminal, very large, and of a white or silver-gray color. In India they appear in February, in Europe and the United States not earlier than June, July, or August. The calyx is smooth and composed of two sepals, which fall when the four petals expand. The ovary is smooth and globular, supports a radiate stigma, and is surrounded by numerous stamens with short, slender filaments and erect, oblong, compressed anthers. The capsule is smooth and glaucous, rounded, from two to four inches in diameter, somewhat flattened at the top and bottom, and crowned with the persistent stigmas, the diverging segments of which are arranged in a circle upon the summit. It contains numerous minute white seeds, which when perfectly ripe escape through small openings between the stigma. In the *black poppy,* the flower, though sometimes white, is usually violet-colored, the capsule somewhat smaller and more globular, and the seeds of a brown or blackish color.

There occur two additional varieties, *Papaver somniferum* var. *setigerum* Elk. and *P. somniferum* var. *glaucum* O. Kuntze, which, however, are not cultivated as sources of opium.

All parts of the poppy contain a white opaque, narcotic juice, but the leaves analyzed by Blondeau, yielded none of the active principles by which opium is characterized. (*J. P. C.,* vii, 214.) It is in the capsule that the juice most abounds and the virtues of the plant chiefly reside, hence this part is sometimes employed medicinally and was official in the British Pharmacopœia of 1898 as *Papaveris Capsulæ* and in the N. F. IV as *Papaveris Fructus.* The dried poppy capsules vary in size from 5 to 7.5 cm. in diameter, and in shape from ovoid to globular, according to the variety of the poppy from which they are procured. Those commonly found in commerce are spheroidal, flattened below, and surrounded by a crown-like expansion—the persistent stigma—which is marked by numerous diverging rays that rise somewhat above the surface and appear to be prolongations of partial septa or partitions, proceeding along the interior circumference of the capsule from the top to the bottom. They are of a dirty white or purplish brown color, of a consistency somewhat like that of paper, inodorous and with little taste unless long chewed when they are decidedly bitter. They contain the same principles as opium but in much smaller amounts. The seeds are destitute of narcotic properties, and are even used as food. The Romans employed them in the preparation of various dainties. They are commercially known as *maw seed* (probably a corruption of the German *mohnsamen*) and frequently used for culinary purposes. They abound with a bland oil, called commercially *poppy seed oil,* or maw oil, which may be extracted by expression. The latter is of a straw-yellow color, without odor, and of a pleasant almond taste. It is without narcotic properties, and much resembles olive oil, as a substitute for which and an adulterant of which it is very largely used on the continent of Europe. It has a low congealing point, thickening only at –15° C. and solidifying at –20° C. The black variety is specially used for the expression of oil, as its culture is easier, and the oil percentage in both varieties is practically the same, ranging between 50 and 60 per cent. As the oil cake generally retains about 8 per cent. of the oil, the yield by expression is from 42 to 50 per cent. Poppy oil contains the glycerides of stearic and palmitic acids, together with those of linoleic, linolenic, and oleic acids. Of the liquid fatty acids, linoleic constitutes about 65 per cent., oleic 30 per cent., and linolenic 5 per cent. Myristic and lauric acid seem to be absent. The oil is an article of much importance on the continent of Europe, particularly in France and Germany, where it is employed for culinary and pharmaceutical purposes, in painting and the manufacture of soap, and in other ways, as substitute for olive oil.

The poppy does not appear to elaborate the milky fluid in which its narcotic properties reside before a certain period of its growth, for we are told that, in Persia, the young plants which are pulled up to prevent too thick a crop, are used as potherbs, and the *μήκων* of the Greeks, which is believed to be identical with the *Papaver somniferum,* is said by Hippocrates to have been nutritive.

Though generally believed to be a native of Asia Minor, this species of poppy grows wild in the south of Europe, and even in England, whither its seeds are supposed to have been brought at a very early period. It was cultivated by the ancient Greeks, and is mentioned by Homer as a garden plant. It is at present cultivated very extensively in India, Persia, Turkey, Macedonia, Bulgaria, China, and Asia Minor, for opium, and in certain parts of Europe chiefly for its seeds. Attempts have been made both in Europe and the United States to produce opium from the poppy, but although it is possible to obtain the product, commercial success has not been, and probably never will be, achieved because of the cost of labor.

For further details on this subject see *U. S. D.,* 20th ed., p. 808. True reports on some experiments in the cultivation of opium poppy in the United States and states that it yields a good crop in Vermont, and a bumper crop in the dry climate of the state of Washington. (*Proc. N. W. D. A.,* 1911, p. 17.) He also outlines a plan for converting the waste product of the poppy seed industry, the capsule, into a valuable source of opium alkaloids. (*Oil, Paint, and Drug Rep.,* 1906, lxx, p. 37.)

The following articles are of interest in connection with the cultivation of the opium poppy: Stahl "On Persian Opium" (*Chem. Zeit.,* xxxii, p. 804); van Itallie and Kerbosch "On Opium in Northern China" (*Arch. Pharm.,* 1910, p. 614); "Opium Cultivation in Turkey" (*C. D.,* lxxxiii, p. 134); "On the Cultivation of Opium at Dorpat" (Muszynski in *Apoth. Zeit.,* xxvi, p. 431).

The opinion that a hot climate is not necessary for the production of the narcotic principles would seem to be established by the facts that the opium of Anatolia is richer in morphine than that of the much hotter regions of Bengal and Upper Egypt, and that good quality of opium has been produced in the northern United States as well as in France and Germany.

Opium is obtained from the capsule of the poppy in a manner almost the same as that described by Dioscorides eighteen hundred years ago. A few days after the petals have fallen from the flower, when the capsule is approaching maturity, horizontal, vertical or spiral incisions into the capsule are made, usually with a several-bladed knife, care being taken not to penetrate the cavity. The white juice which exudes is allowed to harden for twenty-four hours, when it is scraped off by means of a large, blunt knife, a portion of the epidermis of the capsule being removed and constituting about six to ten per cent. of the product. In some places the poppy-head yields opium but once, but in Persia and probably other very hot countries the operation is repeated two or three times after periods of rest. The quality of the product depends largely upon the weather; if this is very hot and dry, the juice will be scanty and very thick, but if the weather is moist the product will be larger but more aqueous. After gathering, the poppy juice is worked up into opium in a manner which differs in different producing countries. An opium-like substance has been in past times, and perhaps even is at present in some districts, produced by making an aqueous extract from the nearly ripe capsule of the poppy. According to the writings of Dioscorides the ancient Greeks were acquainted with both processes of producing the drug from the poppy capsule. The term *ὀπίον,* derived from *ὀπος, juice,* they applied to the substance procured by incisions, which answers precisely to the modern opium. The inspissated expressed juice they called *μηκωνιον,* from *μήκων,* the name of the plant.

Commercial History.—Commerce is supplied with opium chiefly from Turkey, Asia Minor, Macedonia, Jugo-Slavia, Bulgaria, Persia and India. Turkey opium constitutes the principal commercial article. Since the passage of the Narcotic Drugs Import and Export Act in 1922 which established the Federal Narcotics Control Board, the quantities of opium imported into the United States have decreased annually. In 1924, only 87,344 pounds entered this country through legitimate channels.

The commercial opiums may be classified into the following varieties: (1) Turkey opium also known as Asia Minor, Smyrna or Constantinople opium; (2) Macedonian opium, (3) Bulgarian opium, (4) Persian opium, (5) Indian opium, (6) Chinese opium, (7) Egyptian opium.

TURKEY OPIUM (*Smyrna, Asia Minor,* or *Constantinople Opium*).—This opium is produced in the central and northwestern districts of European Turkey, Asia Minor and to a smaller extent also includes some drug sent into Turkey from Bulgaria and Macedonia.

It represents the most important and abundant opium on the American market and is imported chiefly from Constantinople and Smyrna in tin or zinc lined wooden cases.

As seen on our markets it occurs as compressed spheroidal or flattened masses of variable size, usually from half a pound to two or three pounds in weight. These masses usually possess a hard crust on the outside but are soft, plastic, and reddish brown within. They are covered externally with the remains of poppy leaves and with adhering reddish winged fruits of a species of Rumex, the latter being placed in packing between the masses to prevent their cohering. The odor is quite characteristic and the taste bitter.

Two important varieties of Turkish opium now occur in commerce, *viz.,* "Soft shipping opium" and "Druggist's opium." The former opium occurs in masses having a somewhat uniform pasty texture within and containing 25 per cent. to 30 per cent. or more of moisture. The latter variety occurs in harder masses possessing a granular internal appearance, and varies in moisture content from 10 per cent. to 25 per cent.

Considerable soft shipping opium comes from southern Serbia and Malatia; Karahissar, Boghaditz and Giveh supply much of the druggist's opium.

Little of the opium is produced in the immediate neighborhood of Smyrna, the greater portion being brought, on the backs of camels, from a distance of from ten to eighteen days' journey.

In Turkey the district of Anatolia has been a large producing center. The various towns in the Sanjak, or Province of Samsun, which are engaged in the growing of this plant, use Samsun as a port of shipment to Constantinople and European ports. Planting takes place usually in the month of January, and six months must elapse before the plant develops and reaches a height of approximately 3½ feet to 4½ feet. Towards the end of May capsules appear on the plant, and the end of July finds them completely matured. The capsules are then slit and latex is scraped off, which is allowed to dry, and is then exported in round-shaped balls preserved with leaves. After the latex has been completely withdrawn from the unripe capsules, which is allowed to remain on the plant, a new period of ripening sets in; the paste which remains in the capsules, after the latex has been removed, dries and becomes granulous. The buds are then picked and the poppy seeds are withdrawn. These are either white, blue, or greyish in color. Poppy seeds are purchased by Samsun export commission agents from the various centers of production in the interior, and are sent to the coast on the backs of horses, oxen or camels. From there they are exported to various countries where they are used as a food or as a source of oil. Curiously enough, the United States only provides a market for blue seeds, seeming never to be interested in white. According to the opinion of local shippers, this preference on the part of the United States is only one of habit or custom, as there is absolutely no difference between the two kinds of seeds. (*P. J.,* 1921, cvi, 320.)

MACEDONIAN OPIUM.—The opium poppy is cultivated in Greek Macedonia, largely in the regions of Langaza and the peninsula of Chalchidice. While the output of Macedonian opium is comparatively small, this opium has been in great demand by drug manufacturers.

According to Valdegrice, the opium produced in Salonica and environs is free from capsule fragments and contains in the moist condition from 13 per cent. to 17 per cent. of morphine, 0.464 per cent. codeine, and 0.075 per cent. of narceine. (*J. P. C.,* 1918, xviii, 81). The opium produced in Serbian Macedonia according to Brunetti (*P. J.,* 1918, ci, 107) is collected in a number of localities—the most esteemed coming from Kavadar, Veles and Chtap—and is richer in codeine than the opium from Asia Minor.

PERSIAN OPIUM.—This variety of opium is produced chiefly in the vicinity of Shiraz, Ispahan and Mesched, Persia. The latex is collected by the natives from the poppy capsules and kneaded, frequently with added gum, into a homogeneous mass, after which it is cut into brick-shaped masses weighing about a pound, dried in the sun, and wrapped in red or less often white paper and tied with red or yellow string. Occasionally the Persian opium is found in wrapped cones or sticks. It contains less moisture than the Turkey opium and its interior has a homogeneous texture. Its odor is musty and its taste very bitter.

The most important local varieties of Persian opium appear to be the so-called *Mesched opium,* which occurs in grayish-brown shining sticks, wrapped in paper, and *Ispahan opium,* of similar appearance, but of a purer brown color. According to the investigations of Schindelmeiser (*Ap. Ztg.,* 1904, 19) the Mesched opium, when freed from moisture, yields from 5.9 to 8.7 per cent. of morphine; while Ispahan opium has in it from 11.9 to 19 per cent. of the alkaloid. *Tschakida* of the Persians is a dark brown, blackish impure opium occurring in cakes prepared for smoking, and according to Schindelmeiser contains not more than 0.4 per cent. of morphine. W. D. Howard examined a sample of the Persian opium sent to England as "perfectly pure," which yielded to him on analysis, without previous drying—morphine, 10.40 per cent.;

codeine, anhydrous, 0.29 per cent.; narcotine, 2.50 per cent.; thebaine, 0.57 per cent.; cryptopine, 0.09 per cent.; papaverine, a trace. He is unable to say whether it contained any narceine.

Ordinarily but little of the Persian opium enters commerce, most of it being consumed in that country for smoking, but during the world war the Powers, Weightman and Rosengarten Co., of Philadelphia, imported a considerable quantity; they found it to run about 10 per cent. of morphine.

India Opium.—The opium of Hindostan is distributed extensively through continental and insular India, where it is habitually employed as a narcotic. Great quantities were also sent to China, into which it found an easy entrance, notwithstanding prohibitory laws. Much was formerly imported by the East India Company into England, through which a small proportion reached our own country. For various reasons India opium no longer enters Western commerce to any extent. India opium is usually relatively poor in morphine; in many samples the proportion of narcotine is higher than morphine. It is stated that the quality of India opium has much improved since 1914.

There appear to be two chief varieties of it—one produced in Bahar and Benares, in the Bengal Presidency, and called *Bengal opium,* the other in the interior provinces, and designated by the name of *Malwa opium.* For minute description of Indian opium, see *P. J.,* xi, xii, abstracted in *A. J. P.,* xxiv, 118; also *Pharmacographia.*

Bengal Opium, Benares Opium, Patna Opium.—This is produced in Hindostan chiefly under government supervision. The drug as first obtained is semi-liquid, owing to the excessive dews, but is allowed to drain and dry by spontaneous evaporation until only 30 per cent. of moisture is left, when it is taken to the government factories. Great care is exercised to prevent adulteration. In the factories it is worked up with the drainings (known as *passēwā*), poppy petals, and ground poppy plant into balls of standard strength. These are called *"cakes,"* are about six inches in diameter, and are prevented from adhering by being rolled in the ground poppy plant. It is in round balls, weighing three pounds and a half, invested by a coating half an inch thick, composed of agglutinated leaves and poppy petals. The interior of the mass is of a brownish-black color, of the consistence of a stiff paste, and possessed in a high degree of the characteristic odor and taste of opium.

Malwa Opium.—Malwa opium is a variety not made by licensed cultivators on the tablelands of Malwa, northeast of Bengal. Its quality varies greatly. It occurs in round balls. It seems never to be encased in poppy remnants. The masses are commonly quite hard, dry, and brittle, of a light-brown color, a shining fracture, a compact homogeneous texture, and free from mechanical impurities.

Indian Medicinal Opium.—This grade of Indian opium occurred on the markets during the World War, in the form of cubes each weighing about two pounds. It is wrapped in paper that was frequently oiled.

Chinese Opium.—This variety is produced in China and largely used by the Chinese; occasional lots, however, are smuggled into other countries. It occurs in flattened globular cakes that are frequently wrapped in white paper.

Egyptian Opium.—Much opium was formerly produced in Upper Egypt, especially in the district of ancient Thebes, which was supposed to yield it in greatest perfection, hence the term *Opium Thebaicum,* and the old name of laudanum, *Tinctura Thebaica.* The cultivation of the opium poppy in Egypt was prohibited in 1918 in order to increase the area under food cultivation. (*C. D.,* 1918, xc, 846). This variety occurred in flat roundish cakes, of various dimensions, sometimes as much as six inches in diameter and a pound in weight, usually, however, much smaller, and sometimes not weighing more than half an ounce. These cakes were either wrapped in a poppy leaf, so placed that the mid-rib divided the surface into two equal parts, or exhibited vestiges of such a covering. Occasionally the brown color of the opium was seen through the leaf, and the surface appeared as if uncovered, while the leaf was still present. The fracture was conchoidal and of a waxy luster and small fragments of it were translucent. Its color was usually redder than that of Smyrna opium, though sometimes dark. Some of the pieces, on exposure to the air, became damp and sticky on the surface, indicating the fraudulent addition of a deliquescent substance. The odor was similar to that of Smyrna opium, but weaker. It was an inferior variety, as the best of it, examined by Merck, yielded only 6 or 7 per cent. of morphine.

Adulterations.—The adulteration of opium has given rise to much complaint on the part of pharmacists, and various plans of customs legislation have been suggested by which it has been thought that these adulterations could be prevented. It is, however, obviously impossible to pronouncedly affect the action of the semi-barbarians who are engaged in the cultivation of opium, by any American legislation. Usually the substances which are used to adulterate the drug are inert, and therefore do no harm except by weakening its activity. The U. S. Custom House requires that opium, in order to enter the United States as opium, shall conform to the U. S. P. standard and contain not less than 9.5 per cent. of anhydrous morphine.

Sand, ashes, the seeds of different plants, extracts of the poppy, *Lactuca virosa, Glycyrrhiza glabra,* and *Chelidonium glaucum,* gum arabic, tragacanth, salep, aloes, even small stones and minute pieces of lead and iron, are mentioned among the substances employed in the sophistication of the drug. Tschirch (*A. J. P.*, 1898, 488) proposes the use of the Roentgen ray in detecting such adulterations.

Masson described a product which was sold under the name of "Smyrna" or "manipulated," and which consisted of a mixture of the natural juice with substances more or less inert. The samples varied very widely in composition, and in some cases were so altered that the active ingredients could not be readily dissolved. (*J. P. C.*, 1905, p. 529.) Stahl found in some samples of Turkish opium the possible admixture of fruit pulp or fruit extracts. (*Ph. Zentralh.*, xlix, p. 958.) Dried grape-juice mixed with flour was at one time frequently added to the opium juice.

Opium is regarded as inferior when it has a blackish color, a weak or empyreumatic odor, a sweet or slightly nauseous and bitter taste, a soft, viscid, or greasy consistence, a dull fracture, or an irregular, heterogeneous texture, from the intermixture of foreign substances. It should not impart a deep-brown color to the saliva, nor leave a dark uniform trace when drawn over paper, nor form with water a thick viscid solution. The best test is the assay for alkaloids.

Description and Physical Properties.—Good opium has a strong, peculiar odor, and a bitter, somewhat acrid taste. It is officially described as: "In more or less rounded, somewhat flattened, masses, usually about 8 to 15 cm. in diameter; externally dark brown, covered with fragments of poppy leaves and at times with fruits of a species of rumex adhering from the packing; more or less plastic when fresh, becoming hard and brittle or tough on keeping; internally dark brown, interspersed with lighter areas, somewhat lustrous; odor characteristic, narcotic; taste very bitter, characteristic." *U. S.*

"Usually in rounded, irregularly formed, or flattened masses, varying in weight, but commonly weighing from about 250 to 1000 grammes. When fresh, plastic, and internally somewhat moist, coarsely granular, or nearly smooth, and reddish or chestnut-brown; but becoming harder on keeping, and darkening to blackish-brown. Strong and characteristic odor; taste bitter." *Br.*

When long chewed it excites much irritation in the lips and tongue, and may even blister the mouths of those unaccustomed to its use. Its color is reddish-brown or deep fawn; its texture compact; its sp. gr. 1.336. When drawn over paper it usually leaves an interrupted trace of a light-brown color. It is often soft in the interior of the mass, and in this state is tenacious; but when exposed to the air it gradually hardens, and ultimately becomes brittle, breaking with a shining fracture, and affording, when pulverized, a yellowish-brown powder, which becomes adhesive upon a slight elevation of temperature. It readily inflames upon the application of a lighted taper. On heating opium on a watch crystal and collecting the sublimate on a slide, Rosenthaler found the sublimate to give the characteristic red color reaction for narcotine. (*Ph. Zentralh.*, liv, p. 1250; *Apoth. Zeit.*, xxviii, p. 991.)

Opium yields its virtues to water, alcohol, and diluted acids, but not to ether, benzine and some of the other immiscible solvents. To all these menstrua it imparts a deep-brown color. Alcohol dissolves about four-fifths of it. Pelletier stated that the proportion taken up by water varies in the specimens. He never found the quantity of extract prepared with cold water to exceed 12 parts out of 16.

The proportion of morphine which any particular specimen of opium will furnish is considered the best test of its value. The U. S. Pharmacopœia directs that opium, in its normal, moist condition should contain not less than 9.5 per cent. of anhydrous morphine, and powdered or granulated opium, dried at a heat not exceeding 85° C., should contain not less than 10 nor more than 10.5 per cent. of anhydrous morphine when assayed by the official process, which is as follows:

"Place 8 Gm. of Opium, which if fresh should be in very small pieces, and if dry in fine powder, into an Erlenmeyer flask having a capacity of about 250 cc., add 80 cc. of distilled water, stopper the flask, and agitate it every ten minutes (or continuously in a mechanical shaker) during three hours. Then pour the contents as evenly as possible upon a wetted filter having a diameter of not over 12 cm., and, when the liquid has drained off, wash the residue with distilled water, carefully dropped upon the edges of the filter and its contents until a filtrate of 120 cc. has been obtained. Carefully transfer the moist Opium to a mortar by means of a spatula, and rub to a smooth paste, then rinse into the original flask with 50 cc. of distilled water, agitate it thoroughly, and return the whole to the filter. When the liquid has drained off, wash the residue with 75 cc. of distilled water. Evaporate the mixed filtrates and washings on a water bath to about 40 Gm., transfer the extract to a 50 cc. graduated flask, and wash the evaporating dish with sufficient distilled water to make the entire volume measure exactly 50 cc. when cooled to room temperature. Place in a small mortar 4 Gm. of freshly slaked lime, add about 10 cc. of the Opium extract and rub to a smooth paste, then add the remainder of the extract, and rinse the flask with exactly 10 cc. of distilled water, adding the rinsings to the mortar, and stir frequently during fifteen minutes, avoiding unnecessary loss by evaporation. Filter through a dry filter, about 10 cm. in diameter, and transfer exactly 30 cc. of the filtrate, representing 4 Gm. of Opium, to an Erlenmeyer flask of suitable capacity. To this add 2 cc. of alcohol and 15 cc. of ether, and after shaking the mixture add 1 Gm. of ammonium chloride, stopper the flask, and shake it frequently during

UNIVERSITY OF ILLINO
LIBRARY-CHE

half an hour, then set it aside in a cool place for twelve hours or over night. Remove the stopper, and brush any adhering crystals back into the flask. Decant the ethereal layer into a small funnel, the neck of which has been previously closed with a pledget of purified cotton. (A small filter paper may be used if preferred.) Rinse the flask and contents with 15 cc. of ether, and, when the ether has passed through, wash the funnel and cotton with a small quantity of ether, and then pour the aqueous liquid into the funnel without trying to remove the crystals. Wash the crystals in the flask and the contents of the funnel with distilled water previously saturated with morphine, until the washings are colorless. Then add a few drops of distilled water to replace the morphinated water. Incline the edge of the funnel over the mouth of the flask, and by means of a glass rod carefully transfer the cotton with adhering crystals to the flask. Insert the funnel into the neck of the flask, and wash the funnel with 20 cc. of tenth-normal sulphuric acid, followed by 10 cc. of distilled water applied, drop by drop, around the edge of the funnel. Remove the funnel, replace the cork, warm gently, and agitate until the crystals are dissolved. Rinse the cork with distilled water, and titrate the excess of acid with fiftieth-normal sodium hydroxide. Each cc. of tenth-normal sulphuric acid corresponds to 0.02853 Gm. of anhydrous morphine." *U. S.*

Assay of Opium, Br.—" Opium, in No. 50 powder, dried at 60° C., 8 *grammes;* Calcium Hydroxide, freshly prepared, 2 *grammes;* Ammonium Chloride, 2 *grammes;* Alcohol (90 per cent.), Ether, Distilled Water, of each, *a sufficient quantity.* Triturate together the Opium, *calcium hydroxide,* and 20 millilitres of *water,* in a mortar until a uniform mixture results; add 60 millilitres of *water* and stir occasionally during half an hour. To 51 millilitres of the filtered liquid (representing 5 grammes of Opium) in a convenient vessel add 5 millilitres of *alcohol* (90 per cent.), and 25 millilitres of *ether;* shake the mixture; add the *ammonium chloride,* shake well and frequently during half an hour; set aside for twelve hours for the morphine to separate. Counterbalance two small filters; place one within the other in a small funnel in such a way that the triple fold of the inner filter shall be superposed upon the single fold of the outer filter; wet them with *ether;* remove the ethereal layer of the liquid in the vessel as completely as possible by means of a small pipette, transferring the liquid to the filter; rinse the vessel with 10 millilitres of *ether,* again transferring the ethereal layer, by means of the pipette, to the filter; wash the filter with a total of 5 millilitres of *ether,* added slowly and in portions. Let the filter dry in the air, and pour upon it the contents of the vessel in portions, in such a way as to transfer the granular crystalline morphine as completely as possible to the filter. When all the liquid has passed through, wash the remainder of the morphine from the vessel with *morphinated water,* until the whole has been removed. Wash the crystals with *morphinated water* until the washings are free from color; allow the filter to drain, and dry it, first at 60° C. and finally, for two hours, at 115° C. Weigh the crystals in the inner filter, counter-balancing by the outer filter. Dissolve 0.2 gramme of the crystals in 10 millilitres of *N/10 solution of sulphuric acid,* and titrate back with *N/10 solution of sodium hydroxide, solution of methyl orange* being used as indicator. Each millilitre of the acid neutralised by the alkaloid corresponds to 0.0285 gramme of pure anhydrous morphine. The weight of pure anhydrous morphine obtained, as indicated by the titration, plus 0.051 gramme, the average loss of morphine during the process, together amount to 0.5 gramme, representing in 100 grammes of the dry powdered Opium 10 grammes of morphine, calculated as anhydrous. *Limit of error* 0.5 gramme in excess or defect." *Br.*

Morphinated Water.—" Prepared by digesting pure morphine in chloroform water for seven days at a temperature of 15.5° C., with shaking occasionally, so as to obtain a saturated solution of the alkaloid, and filtering from the undissolved morphine." *Br.*

The U. S. and Br. methods of assay are practically identical in principle, belonging to the class of assays known as " lime processes." Experience has proved that the " lime processes " have some objectionable features. They all depend upon the principle that opium in the presence of lime is treated with a definite quantity of water until the latter has extracted as much as possible of the soluble portions, after which a certain portion of the solution, which is *assumed to represent* a corresponding fraction of the weight of the opium, is weighed or measured off, the morphine determined in it. The strength is calculated from the quantity of morphine found in this fraction or aliquot part. The " lime processes," in the hands of ordinary operators, " register too low," the assay being applied to a proportion of the opium which may or may not be an aliquot part of the whole, but is generally less than it is assumed to be, because no allowance is made for the increase in volume due to the solution of the solid constituents of the opium. The British Pharmacopœia overcomes this objection by requiring 104 cc. of liquid to be taken instead of 100 cc. Want of space prevents our giving a critical review of the many methods of assay in use at various times. (Extensive references to the older methods are found in the *U. S. Dispensatory,* 19th ed., p. 905.) See also *J. I. E. C.,* 1912, p. 514; *Gehes. Rep.,* 1912; *Year Book of Pharm.,* 1913, 443.

Chemical Constituents.—It was through the researches into the nature of this substance that chemists were led to the discovery of the alkaloids. To Sertürner, an apothecary at Eimbeck, in Germany, belongs the credit of having opened the important field of alkaloidal research. The development of the alkaloids in opium has been the object of the studies of A. Müller. (*Ph. Ztg.*, lix, p. 600.) He found the seeds to be alkaloid-free, but that the sprouts, after two weeks, show the presence of alkaloids. The alkaloidal content of the plant slowly increases until the flowers appear, when there is a sharp increase lasting until the floral leaves fall. After the ripening of the capsule, the alkaloidal nitrogen content of the entire plant was found to be 0.0094 per cent.; of the stem and leaves alone, 0.0085 per cent.; and of the capsule walls only 0.0168 per cent. The alkaloidal content was found to vary from day to day, being less on cloudy than on sunny days. His conclusions were that the alkaloids of the poppy plant are not excretion material intended to protect the plant from animal enemies, as has been suggested, but that they are present to afford a source of nitrogen for the synthesis of reserve protein. A comprehensive study of the market conditions of the more important opium alkaloids was contributed by L. E. Warren, *A. J. P.*, 1915, p. 439.

In the year 1803 Derosne made known the existence of a crystallizable substance which he had discovered in opium, and which he erroneously believed to be the active principle. In the following year Seguin discovered another crystallizable body, which experience has proved to be the true narcotic principle of opium, but he did not fully investigate its nature, and no immediate practical advantage accrued from his excellent analysis. About the same time, Sertürner was engaged in a similar investigation, the results of which, very analogous to those obtained by Seguin, were published in a German journal, without, however, attracting general attention. In this state the subject remained until 1817, when Sertürner announced the existence of a saline compound in opium, consisting of a peculiar alkaline principle united with a peculiar acid, and clearly demonstrated the precise nature of a substance which, though discovered both by Seguin and himself, had been hitherto but vaguely known. To the alkaloid, in which he correctly conceived the narcotic powers of opium to reside, he gave the name of *morphium,* which has been since changed to *morphine,* in order to render it conformable with the titles of the other alkaloids. The acid he called *meconic,* a term derived from the Greek name of the poppy. The correctness of the statements of Sertürner was confirmed by Robiquet, who also satisfactorily demonstrated that the substance obtained by Derosne and called by him the *salt of opium* was a principle altogether distinct from morphine, though supposed to possess considerable influence over the system. In the belief in its narcotic powers, Robiquet denominated it *narcotine,* a title which it still retains. A number of other alkaloids have since been discovered in opium, although most of these are in very limited amount, and the existence of some is not quite definitely established as it is possible that they are decomposition products, due to the fact that they were reported in mother liquors from which the more valuable alkaloids had previously been extracted.

According to the views of its constitution at present accepted, it contains some twenty-five alkaloids, namely: morphine, codeine, thebaine, papaverine, protopapaverine, pseudopapaverine, papaveramine, laudanine, laudanidine, laudanosine, meconidine, codamine, narceine, narcotine, oxynarcotine, hydrocotarnine, lanthopine, protopine, cryptopine, neopine, tritopine, pseudomorphine and rhœadine. In addition to the above list, *Deuteropine, Opianine, Papaverosine,* and *Porphyroxine* are possible alkaloids that have been announced, but not sufficiently established as yet. Of these several are official and described elsewhere in this work; the remainder are described below in alphabetical order.

There are present also at least two organic acids, lactic and meconic, and three neutral principles, meconin, meconoisin and opionin; these are described on p. .

Of the principles above mentioned, morphine is by far the most important. It is generally admitted to exist in opium united in part with meconic acid in the state of meconate, and to a certain extent also as a sulphate, although A. R. L. Dohme (*A. J. P.*, 1891, p. 168) believes that the results of a dialysis of opium show that the morphine is combined with sulphuric acid alone.

The relative proportion of the various alkaloids differs considerably in samples of opium. The ordinary ranges of the more important alkaloids are: morphine 5 to 15 per cent.; narcotine 2 to 8 per cent.; codeine 0.1 to 2 per cent.; papaverine 0.5 to 1 per cent.; thebaine 0.15 to 0.5 per cent.; narceine 0.1 to 0.4 per cent. The other reported bases are present in only very small proportions. The amount of labor that has been expended in attempting to determine the chemical structure of the opium alkaloids is so enormous that it can not even be summarized here; the interested reader will find an excellent epitome of the subject in Henry's *Plant Alkaloids,* 1924.

CODAMINE.—*Codamina,* $C_{20}H_{25}O_4N$, is isomeric with laudanine, but is readily distinguished from it by the effect of ferric chloride and nitric acid, both of which color it deep green. According to Allen, codamine also gives a dark green coloration with sulphuric acid and, in the presence of a minute quantity of ferric chloride, a greenish-blue. It can be purified by taking advantage of the feeble solubility of its iodide. Codamine crystallizes also from petroleum benzin; but thus obtained it melts at 126° C., while that procured through ether melts at about 120° C. The acid iodide, tartrate, and oxalate are crystallizable.

CODEINE, $C_{18}H_{21}O_3N$ (or $C_{17}H_{17}NO(OH)$.-

OCH_3), and its phosphate and sulphate are now official and are described under *Codeina.* For a paper on the determination of codeine in opium, by Chas. E. Caspari, see *Proc. A. Ph. A.*, 1904, 386.

COTARNINE, $C_{12}H_{15}O_4N$, was first obtained by Wöhlu by the oxidation of narcotine with manganese dioxide in the presence of sulphuric acid. It is also produced from the same source by oxidation with nitric acid. (See *Cotarnine hydrochloride.*)

CRYPTOPINE, $C_{21}H_{23}NO_5$.—This alkaloid was discovered by T. and H. Smith, of Edinburgh. (*P. J.*, 1867.) They obtained it from the weak alcoholic washings of crude morphine after precipitation, by precipitating with milk of lime, and separating from the thebaine by fractional crystallization. (For details of their method, see *U. S. D.*, 19th ed., p. 895.)

The quantity of cryptopine in opium is extremely small but commercial papaverine has been found to contain as much as 4 per cent. of cryptopine. A most exhaustive research on this alkaloid was reported by W. H. Perkin (*Tr. Chem. Soc.*, 1916, cix, 815; 1919, cxv, 713) in which the mystery of its constitution was finally solved.

Cryptopine is without color or odor, and its salts, though at first bitter to the taste, afterward cause a sense of coolness in the mouth, like that produced by peppermint. It melts at 217° C., and, on cooling, crystallizes in radiated forms at 171° C. It is insoluble in water and in ether, very sparingly soluble in alcohol, requiring 1265 parts of that liquid when cold to dissolve it. Chloroform dissolves it almost as freely as narcotine. It has very strong alkaline powers, and forms crystallizable salts with the acids, which are distinguishable from all the other salts of the opium alkaloids by a strong tendency to gelatinize. From all the constituents of opium, except the alkaloids, morphine, codeine, and thebaine, it is distinguished by its strong alkaline properties. From morphine it differs in the effect of strong sulphuric acid, which produces a blue color with the minutest quantity of cryptopine, a blood-red with thebaine, and none with morphine or codeine.

DEUTEROPINE, $C_{20}H_{21}O_3N$, according to Allen, is an alleged homologue of protopine and cryptopine. It requires further examination.

GNOSCOPINE, $C_{22}H_{23}O_7N$, was found by T. and H. Smith in 1878. It is now regarded as optically inactive narcotine. It is crystallizable, melts at 229° C., is soluble in chloroform and carbon disulphide, slightly so in benzene, not in ether. The salts have an acid reaction.

HYDROCOTARNINE, $C_{12}H_{15}O_3N$, is obtained from the mother waters of thebaine, after the removal of cryptopine and protopine with warm petroleum benzin, by precipitation with ammonia; laudanosine, which is also precipitated, is removed by treatment of the benzin solution with sodium bicarbonate. The hydrocotarnine is retained in solution by the benzin, from which the laudanosine has been deposited on cooling. Hydrochloric acid gas being made to pass through this solution, hydrocotarnine hydrochloride crystallizes out. This alkaloid, as the name indicates, can be formed from cotarnine, by the action of zinc and hydrochloric acid. It is a basic hydrolytic product of narcotine (which see). This alkaloid is very soluble in alcohol, acetone, chloroform, benzin, and ether. It melts at 50° C., and loses at 57° C. the half molecule of water with which it crystallizes. Sulphuric acid dissolves it, coloring it yellow in the cold, and crimson red if heated. Nitric acid colors it yellow; ferric chloride does not affect its color. It has been physiologically studied by Stockman and Dott (*B. M. J.*, Jan., 1891), who find that it produces in the lower animals symptoms similar to those caused by narcotine.

LANTHOPINE, $C_{23}H_{25}O_4N$, differs from pseudomorphine in not becoming blue with ferric chloride, and in giving, when entirely pure, with sulphuric and nitric acids, colorless solutions. It forms colorless microscopic prisms, which fuse at about 200° C. Its acid oxalate and tartrate are crystallizable. The alkaloid is crystallizable, does not have an alkaline reaction, is sparingly soluble in hot or cold alcohol, ether, or benzene, but readily soluble in chloroform. (See *U. S. Dispensatory*, 19th ed., p. 896.) According to Allen, it is obtained from the mother liquor, left from the preparation of morphine by the Robertson-Gregory process. It is a weak base, and is colored orange-red by nitric acid, and pale violet by sulphuric acid, the latter color changing to a dark brown on heating.

LAUDANINE, $C_{20}H_{25}O_4N$, as first prepared, is mixed with cryptopine, from which it is separated by dissolving it in acetic acid, and adding a slight excess of diluted solution of sodium hydroxide, by which the cryptopine is entirely precipitated. The liquid being filtered, and treated with ammonium chloride, lets fall the laudanine, which soon assumes the crystalline form. The acetate, with the addition of potassium iodide, gives rise to laudanine hydriodide, from which ammonia separates the base perfectly pure. It crystallizes from its solution in boiling alcohol in transparent granules or hexagonal prisms melting at 166° C. It is lævorotatory, tasteless, and poisonous, the hydrochloride resembling strychnine in its effects. It is dissolved at 18° C. by 647 parts of ether. With ferric chloride it gives a green coloration and with sulphuric acid and ferric oxide, a deep red color. It contains three methoxy groups and one hydroxyl group. It is sometimes accompanied by its isomeride *laudanidine,* which is probably the lævo form. (Hesse, *Ann. Chem.*, 1894, cclxxxiv.) Laudanine is an energetic base, and with potassium hydroxide forms a crystallizable compound. Its salts, except the neutral sulphate, oxalate, and tartrate, are crystallizable.

LAUDANOSINE, $C_{21}H_{27}O_4N$, exists in the mother waters of thebaine, with cryptopine and protopine. It is itself insoluble in water and the alkalies, but it is soluble in alcohol, acetone, and chloroform. It melts at 89° C., and is decomposed at 110° C. Ferric chloride does not color it. Sulphuric acid gives it a rose color in the cold, and violet when heated. Nitric acid transforms it into a nitrobase. The crystals are anhydrous. It forms crystallizable salts, which are soluble and bitter. The complete synthesis of laudanosine has been effected by Pictet and Finkelstein (*C. R. A. S.*, 1909, cxlviii).

MECONIDINE, $C_{21}H_{23}O_4N$, was discovered by Hesse in 1870. It is brownish-yellow, amorphous, alkaline, melts at 58° C., and is not stable, the salts also being easily altered. It is easily soluble in alcohol, ether, benzene, chloroform, and acetone. It is dissolved by sulphuric acid with an olive-green color, and by nitric acid with an orange-red.

MORPHINE, $C_{17}H_{19}O_3N + H_2O$, and its preparations are treated under another head. (See *Morphina.*)

NARCEINE, *Narceina*, $C_{23}H_{27}O_8N.3H_2O$, discovered by Pelletier in 1832, is in white, silky crystals, inodorous, of bitter taste. E. Merck has shown (*Chem. Ztg.*, 1889, p. 525) that the melting point of the ordinary commercial alkaloid of English manufacture is between 150° and 160° C. and the pure base at 170° to 171° C. Out of water at 60° C. it crystallizes with 2 molecules of water, which it loses at 100° C. and at 140° C. another molecule of water escapes, leaving in the fused residue a mixture of bases. Soluble in 375 parts of cold and 220 of boiling water, soluble also in alcohol, and insoluble in ether. It forms a bluish compound with iodine, the color of which is destroyed by heat and the alkalies. It is rendered blue by the action of mineral acids so far diluted as not to decompose it, but it does not, like morphine, become blue by the action of ferric salts, nor red by that of nitric acid. Narceine is a feeble mono-acidic tertiary base, containing three methoxy groups.

Dragendorff announced that solution of narceine gives a crystalline precipitate with the double zinc and potassium iodide. This reaction may be employed with iodine as a test of narceine. If a solution of this salt, with a little iodized water, be added to solutions of narceine, and the mixture then agitated with ether to remove the iodine in excess, a solution containing a very small quantity of narceine will distinctly assume a blue color. The other alkaloids of opium are destitute of this property. (*J. P. C.*, April, 1870, p. 346.) For method of isolating it see Hope and Robinson (*Tr. Chem. Soc.*, 1914, cv, 2085); and for study of its constitution, Freund and Oppenheimer (*B. Chem. G.*, 1909, xlii, 1084).

The discordancy of the statements of physiologists and clinicians concerning the action of narceine can only be explained by the presence of impurities in the specimens used. The pure alkaloid would seem to be very feeble in its influence, Mitchell having taken five grains without any other effect than causing some headache. The narceine of commerce has been used in doses of one-third to three-fourths of a grain (0.021–0.048 Gm.) as a mild narcotic, probably acting through contaminating morphine.

NARCOTINE. *Narcotina*, $C_{22}H_{23}O_7N$.—It exists in opium, chiefly, at least, in the free state, and is left behind in considerable quantity when the drug is macerated with water. It is white, tasteless, and inodorous, and crystallizes in silky flexible needles, usually larger than the crystals of morphine, fusible at 175° C., and decomposes at higher temperaure with evolution of ammonia. Heated to 220° C., the residue which remains is *hemipinic acid*, $C_{10}H_{10}O_6$, insoluble in cold water. With acids narcotine forms unstable salts that are dissociated by water. The alkaloid can be extracted by immiscible solvents from acid solutions. Its salts are dextrorotatory. It is a weak mono-acidic tertiary base which is convertible into narceine. It has been synthesized by Perkin and Robinson (*Tr. Chem. Soc.*, 1911, xcix) by the union of meconin and cotarnine. It is decomposed by long boiling, or by heating with nitric acid, into cotarnine and meconin, $C_{10}H_{10}O_4$, and by heating with water to 100° C. in sealed tubes, into hydrocotarnine and opianic acid, $C_{10}H_{10}O_5$, while, on the other hand, the action of nascent hydrogen (from zinc and hydrochloric acid) converts it into hydrocotarnine and meconin, and that of oxidizing agents into cotarnine and opianic acid.

It may be distinguished from morphine by its insipidity, by its solubility in ether and insolubility in alkaline solutions, by not affecting vegetable colors, by assuming a yellowish instead of a blood-red color under the action of strong nitric acid, by not decomposing iodic acid, and by not producing a blue color with ferric salts. It is, however, reddened by a mixture of nitric and sulphuric acids. Hence, if to a mixture of it with strong sulphuric acid a small piece of potassium nitrate is added, a deep blood-red color is produced; while morphine, under the same circumstances, yields a brownish or olive green color. It gives a greasy stain to paper when heated upon it over a candle. Water extracts narcotine partially from opium, in consequence of the acid which the latter contains, either free or combined with the narcotine. It may be separated by the action of ether, which dissolves it without affecting the morphine, and yields it upon evaporation. It may also be obtained by digesting opium in ether, and slowly evaporating the ethereal solution, which deposits crystals of narcotine. The proportion of narcotine in opium varies extremely in the different varieties, and in different specimens of the same variety. Thus, in Smyrna opium it has been found by different observers, in quantities varying from 1.30 to nearly 11 per cent. Though narcotine itself is tasteless, its salts are very bitter, even more so than those of morphine. (Berzelius.) Their solution reddens litmus, and yields precipitates with the alkalies and infusion of galls. For physiological study of the methylamide derivatives of narcotine (*narcotine methylamide*), see *V. A. P. A.*, 142, 1895.

Anarcotine, described as an alkaloid especially abundant in the India opium (Roberts, *B. M. J.*, 1895, ii), appears to be simply impure narcotine. (*Merck's Jahresber.*, 1896, 101.)

The substance described as *opianine* is probably an impure narcotine.

For account of the physiological properties of narcotine see *Uses.*

NEOPINE, $C_{18}H_{21}O_4N$, was discovered by T. and H. Smith in the final mother liquors obtained in the extraction of opium alkaloids and was confirmed by Dobbie and Lander. (*Trans. Chem. Soc.*, 1911, 34.)

It gives color reactions and an absorption spectrum similar to codeine of which it is believed by some authorities to be an isomeride.

OXYNARCOTINE. *Oxynarcotina,* $C_{22}H_{23}O_8N$.—This alkaloid accompanies narceine, from which it can be separated by treating the mixture with dilute sulphuric acid. According to Beckett and Wright (*J. Chem. S.*, 1876), it crystallizes out of alcohol in very fine needles, which are difficultly soluble in boiling water and boiling alcohol, insoluble in other neutral solvents. Heated to 140° or 150° C. it is carbonized. It is oxidized by ferric chloride to *hemipinic acid* and *cotarnine,* thus proving its close relationship to narcotine. It is a monacid base, and forms crystallizable salts. There is some doubt as to its chemical individuality.

PAPAVERAMINE, $C_{21}H_{25}O_6N$.—This alkaloid was also obtained by Hesse (*J. P. C.*, 1903, lxviii) in purifying papaverine. It gives an intensely violet blue coloration with sulphuric acid.

PAPAVERINE. *Papaverina,* $C_{20}H_{21}O_4N$.—The discovery of this alkaloid was announced by G. Merck in 1848. It is crystallizable in needles, fusing at 147° C., insoluble in water, very sparingly soluble in cold alcohol or ether, more soluble in these liquids boiling hot, and deposited by them on cooling. It behaves as a monoacidic base and with acids it forms salts, most of which are very sparingly dissolved by water. By the action of hydrochloric acid at 130° C., however, it is decomposed into methyl chloride and homopyrocatechol. By the action of concentrated nitric acid there is formed, on heating, the nitrate of nitropapaverine, $C_{20}H_{20}(NO)_2O_4.NHNO_3$, which separates in crystals. The nitro-base can be separated in clear yellow flocks by the addition of ammonia. By the action of tin and hydrochloric acid there is formed a tetrahydropapaverine, $C_{20}H_{25}O_4N$. Cold concentrated sulphuric acid does not color it, but on warming a violet color is obtained.

For account of its physiological properties see under *Uses.*

PORPHYROXINE, $C_{19}H_{23}O_4N$, was discovered in Indian opium by Rakshit (*Tr. Chem. Soc.*, 1919, cxv) after the name had previously been applied by Merck on 1837 to a product which was subsequently found to be a mixture of alkaloids. According to K. L. Dey (*P. J.*, 1882, xii, p. 397), it is a definite basic substance, always present in Indian opium, but absent from Turkey or Smyrna opium.

Solutions of this alkaloid become red upon exposure to air.

PROTOPINE, $C_{20}H_{19}O_5N$ (*Macleyine, Fumarine*).—Hesse separated it from cryptopine. Both are precipitated as insoluble hydrochlorides by hydrochloric acid in excess; but if the precipitate be dissolved by an excess of oxalic acid, the acid cryptopine oxalate will crystallize, and protopine remain in the mother waters. The liquid is separated, precipitated by ammonia, and agitated with ether, and the ethereal solution is taken up by hydrochloric acid. Protopine hydrochloride being dense and granular, while cryptopine hydrochloride is very light, the two are separated by levigation—eighty grammes of crude cryptopine furnishing one and a half of protopine. Separated from the hydrochloride by ammonia, protopine constitutes a crystalline powder, insoluble in water, soluble in alcohol and in hot petroleum benzin and acetone, more soluble in chloroform, insoluble in the alkalies generally, but slightly soluble in ammonia. It melts at 202° C., undergoing decomposition, and is in anhydrous crystals. Ferric chloride does not color it; nitric acid colors it yellow; sulphuric acid dissolves it, coloring it first yellow, then red, and lastly violet. The alcoholic solution has an alkaline reaction. The salts are neutral and crystallizable.

For studies of its structure see Perkin, *Tr. Chem. Soc.*, 1916, cix, 875 and 1023.

E. Schmidt (*A. Pharm.*, 1893, ccxxxi, 136) states that protopine is identical with *macleyine,* an alkaloid, which has been found by Eykman in *Macleya cordata,* and that it is also found in *Sanguinaria canadensis, Stylophorum diphyllum, Eschscholtzia californica,* and other plants. (See Danckwortt, *A. Pharm.*, 1912, ccl, 590.)

PSEUDOMORPHINE.—*Pseudomorphina,* $C_{34}H_{36}O_6N_2$, was discovered by Pelletier in 1835, and is said by Hesse to be identical with Polstorff's *oxydimorphine;* but, as it exists in small quantities, and was thought to be only an occasional ingredient in opium, little attention has been paid to it. It has also been termed *dehydromorphine.* An interesting fact, however, in relation to it, and one of some toxicological importance, is that it possesses two properties considered characteristic of morphine, those, namely, of being reddened by nitric acid and of producing a blue color with ferric salts, and yet it is without any poisonous influence upon the animal economy. (*J. P. C.*, xxi, 575.) It is prepared from morphine by oxidation with the presence of potassium permanganate in the presence of sodium bicarbonate. It is tasteless, insoluble in water, alcohol, ether, chloroform, and diluted sulphuric acid, but easily soluble in solution of potassium and sodium hydroxide, and lime, and in alcoholic solution of ammonia, though sparingly in an aqueous solution of ammonia. It does not neutralize hydrochloric acid, dissolves in concentrated sulphuric acid with the production of an olive-green color, in concentrated nitric acid with an intense orange-red, and in solution of ferric chloride with a blue color. At 120° C. it loses two molecules of water of crystallization, and at higher temperatures is decomposed without melting. It forms sparingly soluble salts with sulphuric, nitric, oxalic, and tartaric acids, and a crystalline deposit, very slightly soluble in hydrochloric acid, with solution of corrosive sublimate. (*Chem. News,* 1867, p. 188.) Hesse is of the opinion that pseudomorphine is identical with the oxymorphine prepared by the action of oxidizing agents upon morphine by Schutzenberger.

PSEUDOPAPAVERINE, $C_{21}H_{21}O_4N$, was obtained by Hesse (*J. P. C.,* 1903, lxviii) from commercial papaverine. It gives no coloration with sulphuric acid.

RHŒADINE, $C_{21}H_{21}O_6N$, discovered by Hesse in 1865, is described under *Rhœados Petala.*

THEBAINE (*Paramorphine*), $C_{19}H_{21}O_3N$ (or $C_{17}H_{15}ON(OCH_3)_2$), was discovered by Thiboumery (1835) in the precipitate thrown down from an infusion of opium treated with milk of lime. It occurs to the extent of from 0.1 to 1.0 per cent. in opium. It is white, crystallizable, and of an acrid and styptic rather than bitter taste, fusing at 193.4° C., and, according to Hesse, confirmed by D. B. Dott, is not sublimable. Other observers state that it sublimes at 135° C. without fusing, and is deposited in minute crystals resembling caffeine. It is scarcely soluble in water, very soluble in alcohol and ether when cold, and still more so when heated, and capable of combining with the acids, with which it forms salts not crystallizable from their aqueous solution. Alkalies precipitate it from its acid solutions, and unless in very concentrated solution, do not dissolve it when added in excess. It is not like morphine, reddened by nitric acid, nor does it become blue with solutions of ferric salts. Its distinguishing color reaction is a blood-red color with sulphuric acid which changes to orange yellow and eventually to olive green on warming. (See Reichard, *Ph. Centralh.,* 1906, xlvii, 623.)

In its chemical structure thebaine is closely related to morphine and codeine, probably being, like them, a phenanthrene derivative. For account of its physiological properties see under *Uses.*

Thebaine salicylate is practically insoluble in water; hence in the assay of opium the German Pharmacopœia directs the addition of sodium salicylate to the aqueous solution, thus removing the thebaine before precipitating the morphine.

TRITOPINE, $C_{42}H_{54}O_7N_2$, was discovered in 1890 by Klauder. (*A. Pharm.,* 1890, ccxxviii, 419.) It resembles morphine and laudanine in being soluble in sodium hydroxide solution, but is precipitated in the form of an oil by a large excess of the reagent. Tritopine crystallizes in characteristic, anhydrous, transparent, needle-like plates, melting at 182° C., easily soluble in chloroform, but only slightly so in ether. With sulphuric acid it behaves like laudanine. It appears to be a divalent base.

XANTHALINE, $C_{37}H_{36}O_9N_2$, is a base obtained by T. and H. Smith (*P. J.,* 1893, 772) from the acid mother liquors resulting from the crystallization of morphine or codeine hydrochloride, and purification of the product.

The non-nitrogenous principles in opium include two acids and three neutral bodies. One of the acids, which was discovered by T. and H. Smith, of Edinburgh, and at first named by them *thebolactic acid* under the supposition that it differed from ordinary lactic acid, was shown by Buchanan (*B. Chem. G.,* 1870) to be identical with it. Lactic acid appears to be a constant ingredient in opium.

MECONIC ACID, $C_7H_4O_7 + 3H_2O$, is in white crystalline scales, of a sour taste followed by bitterness, fusible and volatilizable by heat, soluble in four parts of boiling water, soluble also in cold water and alcohol, with the property of reddening vegetable blues and forming salts. Its compounds with the earths and heavy metallic oxides are generally insoluble in water. Its characteristic properties are that it produces a blood-red color with ferric salts, which is not destroyed by mercuric chloride as is the similar reaction produced by sulphocyanates, a green precipitate with a weak solution of ammoniated copper sulphate and white precipitates—which are soluble in nitric acid—with lead acetate, silver nitrate and barium chloride. It is obtained by macerating opium in water, filtering the infusion, and adding a solution of calcium chloride. Calcium meconate and sulphate are precipitated. The precipitate, having been washed with hot water and with alcohol, is treated with diluted hydrochloric acid at 82.2° C. The calcium meconate is taken up, and, upon the cooling of the liquid, calcium bimeconate is deposited. This is dissolved in warm concentrated hydrochloric acid, which deposits pure meconic acid when it cools. It may be freed from coloring matter by neutralizing it with potassium hydroxide, decomposing the meconate thus obtained by hydrochloric acid, and again crystallizing. When heated, it loses first its water of crystallization, and then at 120° C. a molecule of CO_2, and yields *comenic acid,* $C_6H_4O_5$; this at 260° C., or over, loses another molecule of CO_2, and yields *pyrocomenic acid,* $C_5H_4O_3$. By the action of nascent hydrogen (from sodium amalgam) it yields *hydromeconic acid,* $C_7H_{10}O_7$. Meconic acid has little or no action on the system, and is not used separately in medicine; but its natural relation to morphine requires that it should be understood. The three related compounds, meconic acid, comenic acid, and pyrocomenic acid, are now considered to be derivatives of the fundamental compound *pyrone,* $\mathrm{CO}<\genfrac{}{}{0pt}{}{\mathrm{CH}=\mathrm{CH}}{\mathrm{CH}=\mathrm{CH}}>\mathrm{O}$. Thus, from pyrone, $C_5H_4O_2$, are obtained *oxypyrone* (pyromeconic acid), $C_5H_3O_2(OH)$, and *oxypyrone-carboxylic* (comenic) *acid,* $C_5H_2O_2(OH)COOH$, and *oxypyrone dicarboxylic* (meconic) *acid,* $C_5HO_2(OH)(COOH)_2$. Pyrone itself is formed when comenic and chelidonic acids are heated to 250° C. Most of the pyrone derivatives are converted by the action of ammonia into pyridone and pyridine compounds.

Meconic acid was formerly recognized by the British Pharmacopœia, but was dropped at the 1898 revision. It appears to be nearly free from active physiological properties. Sertürner took 4.5 grains of sodium meconate, and Grape and Loewer 12 grains of the pure acid, without the production of any symptoms, while, according to Mulder, Pereira, Lange, and others, 20 grains of the acid cause no sensible effect in the dog.

Meconin (*Opianyl*), $C_{10}H_{10}O_4$, a neutral principle before referred to, the existence of which was announced in 1832, by Couërbe, is identical with a substance discovered several years previously by Dublanc, Jr., but of which no account was published. It occurs also in *Hydrastis* and has been synthesized from guaiacol by Fritsch (*Ann. Chem.*, 1898, ccci). It may also be produced by the oxidation of narcotine with nitric acid. It is perfectly white, in the form of acicular crystals, soluble in about 265 parts of cold and 18 of boiling water, very soluble in alcohol, chloroform, and the essential oils, but only sparingly in ether; fusible under water at 77° C., *per se* at 110° C., sublimable on careful heating, and possessed of a degree of acrimony which favors the supposition that it may not be without action upon the system. It is neither acid nor alkaline, and contains no nitrogen. The method by which it was obtained from opium is described in the *U. S. D.*, 20th ed., p. 816.

Meconoisin, $C_8H_{10}O_2$, was discovered by T. and H. Smith in 1878. Meconin, upon being left to itself for some days, sets into a mass of crystals. These crystals, upon being drained and cautiously washed with cold weak spirit, are to be boiled in a large quantity of water. The filtered liquid gives a crystallization of meconin, and the mother liquor, when concentrated, and yields crystalline masses of meconoisin, associated with meconin. It is a crystallizable neutral body which has a melting point of 88° C. It may be distinguished from meconin by the following test of T. and H. Smith. "When heated with slightly diluted sulphuric acid, and when the evaporation has reached a certain point, meconin produces a beautiful green color. With meconoisin, under the same circumstances, the coloration is deep red, becoming purple." This substance has been found by Stockman and Dott (*B. M. J.*, Jan., 1891) to be a tetanizant.

Opionin was found by Hesse in small quantities in Smyrna opium. It forms white needles, which melt at 227° C. These are insoluble in water, but dissolve in alkalies, alcohol, and ether.

Tests for Opium.—It is sometimes highly important to be able to ascertain the presence or absence of opium in any suspected mixture. As meconic acid and morphine have been found only in the products of the poppy, if either or both of them be shown to exist in any substance, very strong evidence will be afforded of the presence of opium. The test should, therefore, be applied in reference to the detection of these two principles. If an aqueous infusion of the substances examined yields a red color with the tincture of ferric chloride, there is presumptive evidence of the presence of meconic acid. Greater certainty may be obtained by the following process. Add in excess to the filtered liquor a solution of lead acetate. If opium be present, there will be a precipitate of lead meconate, and the morphine and lead acetates will remain in solution. The precipitate is then to be suspended in water, and decomposed, either by adding a little diluted sulphuric acid, which forms lead sulphate and leaves the meconic acid in solution, or by passing through it a stream of hydrogen sulphide, removing by filtration the precipitated lead sulphide, and heating the clear liquor, so as to drive off the hydrogen sulphide. With the clear liquor thus obtained, if it contain meconic acid, the tincture of ferric chloride will produce a striking red color, ammoniated copper sulphate a green precipitate, and lead acetate, silver nitrate, and barium chloride, white precipitates soluble in nitric acid. Potassium sulphocyanate, which, according to Wright, is an invariable constituent of saliva (*Simon's Chemistry,* ii, 6), produces a red color with ferric salts, resembling that produced by meconic acid, but, according to Everitt, this color is entirely and at once destroyed by a solution of corrosive sublimate, which has no effect on the red color of iron meconate. (*A. J. P.*, xii, 88.) On the contrary, gold chloride reddens a solution of sulphocyanic acid or a sulphocyanate, but not of meconic acid. Pereira says the acetates also redden ferric salts, but do not afford the results just mentioned with lead acetate and barium chloride. To test for the presence of morphine, the liquid from which the lead meconate has been precipitated, and which may be supposed to contain the morphine and lead acetates, must be freed from the lead by a stream of hydrogen sulphide, the hydrogen sulphide driven off by heat, the solution then alkalized and extracted with a mixture of three parts of chloroform with one part of alcohol; after evaporation of the solvent tests for identity may be applied to separate portions of the residue: such as general alkaloidal reagents for the detection of an alkaloid; and the specific identity tests given under *Morphina*, viz., nitric acid, which colors the morphine red.

Incompatibles.—The substances which produce precipitates with opium do not all necessarily affect its medicinal virtues, but the alkalies, and all vegetable infusions containing tannic acid, are incompatible, the former separating and precipitating the free alkaloids, the latter forming with it an insoluble compound.

Uses.—The use of opium as a medicine can be clearly traced back to Diagoras, who was nearly contemporary with Hippocrates, and it was probably employed before his time.

Opium owes its activity chiefly to the alkaloid morphine and the physiological actions and therapeutic uses of the whole drug are very similar to those of its dominant alkaloid. Sufficient has been said on this subject under *Morphina*. Certain of the other alkaloids present in opium differ somewhat in their action from that of morphine, and to a certain extent modify the effects of opium, and we shall therefore consider here the medical properties of some of these secondary alkaloids, and point out the conditions in which opium is preferred to morphine.

The most abundant of the alkaloids after morphine is *narcotine;* indeed, in some varieties of opium it is said to be present in larger quantities than morphine. This alkaloid appears to be almost, if not entirely, free of the characteristic narcotic properties of morphine. In large doses it is a spinal stimulant and produces in the lower animals convulsions. According to Macht (*J. P. Ex. T.*, 1915, vii, p. 339), narcotine differs essentially from morphine in its action upon the respiratory center, acting as a stimulant rather than a depressant. He finds also that because of this antagonistic action upon respiration very much larger doses of morphine can be given if combined with narcotine, without dangerous respiratory depression. It was at one time recommended as an antiperiodic, but is probably of no value; the *dose* employed was from two to three grains (0.13–0.2 Gm.).

Papaverine is the only other alkaloid which occurs naturally in opium in large enough quantity to perceptibly modify the effect of the crude drug. Although much less potent than morphine it possesses distinct narcotic powers. According to Pal (*D. M. W.*, 1914, xl, p. 164) papaverine is an active local anesthetic and is especially valuable because of its power in allaying spasm of the involuntary muscles. Macht (*loc. cit.*) finds that papaverine, like narcotine, antagonizes morphine in its effect upon the respiratory center. In 1892 Lebuscher showed that papaverine lessened intestinal peristalsis and more recently Macht has shown that it is a depressant to all unstriped muscles. Papaverine has been recommended in clinical medicine in *diarrhea*, various forms of *gastric* or *intestinal spasms, asthma, biliary colic,* and other conditions of excitability of the involuntary muscles. It, as well as its hydrochloride and sulphate, are recognized by the *N. N. R.*, 1924. The *dose* recommended is usually from one-half to one and one-half grains (0.032–0.096 Gm.), although it is stated that much larger quantities may be given without any evil effects.

Thebaine.—This is chiefly of interest because of its action on the spinal cord. In the lower animals it produces convulsions closely simulating those caused by strychnine. In large quantities it seems to be paralyzant to the peripheral motor nerves. It does not appear to possess narcotic properties.

Codeine being official is considered elsewhere. The other alkaloids occur in such small quantities and are mostly of such feeble powers that it is improbable that they play any part in the effects of opium. For further information on the minor alkaloids of opium, see Crawford and Dohme (*Proc. A. Ph. A.*, 1902, p. 472); Leubuscher (*D. M. W.*, 1892); Macht (*J. P. Ex. T.*, 1915, vii, and 1916, viii); and Pal (*D. M. W.*, 1913, xxxix, and 1914, xl).

In a general way it may be said that opium is more constipating and more nauseating in proportion to its narcotic power than is morphine. According to the experiments of Macht, which have received clinical confirmation from the observations of Sahli and others, it would appear that it is also less dangerous because relatively less depressing to the respiratory center. The fact that opium is more constipating than morphine is probably attributable to its papaverine. Although capable of fulfilling all the indications for which morphine is employed, when used as an analgesic or somnifacient, the alkaloid is usually preferred because of its lesser liability to disturb digestion. On the other hand in *diarrhea* and *spasmodic colic* the whole drug is superior to the alkaloid. Opium is frequently a valuable remedy in *diabetes mellitus*. How it acts is uncertain, but the whole drug is to be preferred to any of its alkaloids. Because of its peculiar power in dilating the vessels of the skin opium tends to increase the sweat and is therefore useful in minor infections, such as *colds, grippe, muscular rheumatism,* and the like. As a sudorific it is generally combined with ipecac in the form of Dover's Powder.

Opium is largely used locally in the form of its tincture either in combination with a solution of lead subacetate or by itself. While it possesses feeble counter-irritant and anesthetic powers the freedom with which it is used as a local application verges on the superstitious.

Recognizing the superior advantages of opium over morphine in some conditions, and the desirability of hypodermic administration, a number of manufacturing chemists have put upon the market preparations which profess to represent all of the alkaloids of opium in approximately their natural proportions; among these may be mentioned *pantopon, alcopon,* *glykopon* and *toponal. Holopon* is an opium preparation asserted to be prepared by dialysis and representing, therefore, only the crystallizable constituents of opium. *Opon* is asserted to contain all the other active ingredients of opium except morphine.

Poisoning.—In moderately large doses opium produces, generally, a pleasurable feeling of languor followed by drowsiness. In toxic dose the most prominent symptom is sleep, from which, in the moderate degrees of poisoning, the patient can easily be awakened by loud noises, shaking, etc. At this stage of the poisoning the respirations are generally slower than normal but of good depth, the pulse is slow and full, the skin warm and flushed and moist, the pupil contracted. As the intoxication deepens the respirations become slower and shallower and often irregular, and the skin is frequently more or less cyanotic from imperfect aeration of the blood; the pupils grow smaller and are eventually reduced in size to almost complete invisibility; the patient can be aroused only with difficulty and when left to himself immediately sinks back into a comatose sleep. The reflexes are generally not greatly affected. When the dose has been very large there may develop, late in the poisoning, failure of the circulation with rapid, feeble pulse and cold, clammy, cyanotic skin. The quantity required to take life varies enormously according to the individual susceptibility of the patient. On the one hand, several fatalities have been reported from less than one-half a grain of morphine and from four or five grains of opium. On the other hand, we have seen an opium habitué take 8 grains of morphine at a dose with no serious effect, and Fell has reported recovery following 33 grains of morphine.

Treatment of Opium Poisoning.—For the evacuation of the stomach, unless the drug has been taken in solid form, the stomach tube is preferable to emetics, the latter often failing to act because of the effect of the drug upon the vomiting centre. In the absence of a stomach tube, however, twenty or thirty grains of zinc sulphate may be given as an emetic. The best chemical antidote is potassium permanganate, which oxidizes the active principle of the drug to a harmless compound; four or five grains of the permanganate may be given at a dose. Where the stomach tube is employed it is well to wash out the stomach with a 1 to 500 solution of potassium permanganate leaving 3 or 4 ounces of this solution in the stomach to neutralize any alkaloid which may be later excreted. If this antidote be not at hand tannic acid may be used as a partial but less satisfactory antidote; it is well to follow this with a saline cathartic as the tannate of morphine is slowly absorbable. Fantus has obtained favorable results in experimental morphine poisoning with the use of fuller's earth (see *Terra Silicea Purificata*). Aside from the prevention of absorption, the most important measures are those directed towards maintaining respiratory function. As this is always in abeyance during sleep the patient should, if possible, be kept awake. Many of the measures, however, which have been employed for preventing sleep have done as much harm in exhausting the patient's strength as the wakefulness has done good. By far the best means for this purpose is the faradic battery, using either a brush electrode or a bare metal upon the skin; with this apparatus an exquisite pain can be caused without any injury to the body. Slapping the skin with the fringe of a wet towel is also useful, but care must be exercised not to bruise. Alternate dashes of hot 40.5° C. and cold water 10° C. upon the bare chest may also be of service. Occasionally by repeated shouting the patient may be kept from going to sleep. We do not believe that the advice, so often given, to keep the patient constantly walking is sound. Among the respiratory stimulants the most useful is probably cocaine or strychnine; caffeine and atropine are also of much service. There was at one time a wide-spread belief that atropine was a complete physiological antagonist to morphine. This, however, is erroneous; while the drug may be useful for its stimulating effects upon the respiratory center, it must be remembered that large doses of atropine are depressant, and if used too freely may injure rather than benefit. If, despite these measures, respiration remains dangerously insufficient, recourse should be had to artificial respiration either by the Sylvester or Schaefer method, or preferably with one of the apparatuses for forced artificial respiration, such as the pulmotor. By means of a simple bellows apparatus Fell (*Medical Examiner,* June, 1899) succeeded in maintaining life for seventy-three hours with the eventual recovery of the patient. The intravenous injection of salt solution has also been recommended with the idea of diluting the poison in the blood. Cardiac stimulants, as ammonia, may occasionally be required in severe cases.

Opium Habit.—The use of opium or one of its various derivatives, especially morphine and diacetyl morphine, is one of the most common and one of the most injurious of drug addictions. In the Orient it has been commonly employed by smoking but among the European peoples the hypodermic needle has been the favorite method of the morphine addict; diacetylmorphine is usually taken as a snuff. Owing to the vigorous campaign which has been waged against these habits in the United States, they seem to be rapidly diminishing. The amount of opium imported into the U. S. reached a maximum in 1911 of over 600,000 pounds. Since then, however, it has been continually decreasing and now (1924) amounts to less than 50,000 pounds annually. Of course, this does not take into consideration the quantities which are smuggled into this country. For study of drug addiction in the U. S. and reference to the literature on the subject, see Kolb and DuMez, *U. S. Pub. Health Rep.*, May 23rd., 1924. For elaborate study of the chemistry of smoking opium see *Ap. Ztg.*, 1903.

Dose, from one to two grains (0.065–0.13 Gm.).

Off. Prep.—*From opium.*—Extractum Opii Liquidum (from Dry Extract), *Br.;* Extractum Opii Siccum, *Br.;* Linimentum Opii (from Tincture), *Br.;* Opium Pulveratum, *U. S.;* Opium Granulatum, *U. From granulated opium.—Tinctura Opii, *U. S.;* Tinctura Opii Crocata, *N. F.*

OPIUM GRANULATUM. U. S.

GRANULATED OPIUM Opium Gran.

"Opium dried at a temperature not exceeding 70° C., and reduced to a coarse powder. Granulated Opium yields not less than 10 per cent. and not more than 10.5 per cent. of anhydrous morphine. Granulated Opium of a higher morphine percentage may be brought within the required limits of strength by admixture with granulated opium of a lower percentage, or with some inert diluent.

"**Assay.**—Proceed as directed under *Opium.*" *U. S.*

This form of opium was introduced into the U. S. P. because, on account of its being in coarse powder, it is better fitted for use in making the liquid preparations of opium. (See *Opium.*)

Granulated opium is prepared by a special milling and sifting process, the finer portions being separated and used in the preparation of powdered opium. Cocoanut shells, coarsely ground, have been found satisfactory as a diluent for reducing granulated opium of a high assay strength to the U. S. standard.

Dose, one to two grains (0.065–0.13 Gm.).

OPIUM PULVERATUM. U. S.

POWDERED OPIUM Opium Pulv. [Opii Pulvis U.S.P. IX, Opii pulvis P.I.]

"Opium dried at a temperature not exceeding 70° C. and reduced to a very fine powder. Powdered Opium yields not less than 10 per cent. and not more than 10.5 per cent. of anhydrous morphine. Powdered Opium of a higher morphine percentage is to be reduced to the official standard by admixture with powdered opium of a lower percentage, or with some inert diluent." *U. S.*

Poudre d'Opium, *Fr. Cod.;* Opiumpulver, *G.;* Polvo de opio, *Sp.*

Description and Physical Properties.—"Light brown, consisting chiefly of yellowish-brown to brownish-red, more or less irregular and granular fragments, varying from 0.015 to 0.150 mm. in diameter; a few fragments of strongly lignified, thick-walled, 4- to 5-sided or narrowly elongated, epidermal cells of the poppy capsule; very few fragments of tissues of poppy leaves, poppy capsules, and rumex fruits. In addition, there will be the microscopic characters of the diluent, if any has been used in the preparation of the powder.

"**Assay.**—Proceed as directed under *Opium.*

"Preserve in well-closed containers." *U. S.*

For chemistry, uses, etc., see under *Opium.*

Under the name of *Opium Deodoratum* (*Deodorized Opium, Denarcotized Opium*) the U. S. P. formerly recognized a preparation freed from certain nauseating constituents. This was prepared as follows:

"Powdered Opium, *five hundred grammes;* Purified Petroleum Benzin, *a sufficient quantity.* Macerate the powdered opium for twenty-four hours in a wide-mouthed, well-closed bottle with sufficient purified petroleum benzin to cover it completely, shaking the mixture occasionally. Then decant the clear benzin layer as closely as possible and repeat the maceration for twenty-four hours with another portion of purified petroleum benzin. Again decant the clear benzin layer and transfer the remaining contents of the bottle to a plain filter. Closely cover the funnel, allow the mixture to drain and then slowly percolate the residue with purified petroleum benzin until the latter passes through without color. Remove the filter containing the Opium from the funnel, expose the powder to the open air, so that it may dry thoroughly, and add sufficient sugar of milk to restore the original weight. Care should be used to guard against the danger due to the inflammability of the benzin. Granulated opium may also be deodorized in the manner directed above." *U. S. IX.*

ORTHOCRESOL. N. F.

ORTHOCRESOL

"The ortho variety of cresol [$C_6H_4.CH_3OH$-1:2 (108.10], obtained from coal tar." *N. F.*

For description of the origin and general properties of this substance see under *Cresol.*

Description and Physical Properties.—"Orthocresol occurs as white crystals or as a colorless or yellow to brown, highly refractive liquid, becoming darker with age and exposure, and having a phenol-like odor. Slightly soluble in water; soluble in alcohol, ether, and chloroform. Miscible with an equal volume of solution of formaldehyde with the production of a transparent solution.

"Specific gravity about 1.05; melting point about 30° C.; boiling point about 190° C. A saturated solution of Orthocresol is neutral or slightly acid to litmus and becomes blue-violet on the addition of ferric chloride T.S.

"Preserve it in well-closed containers, protected from light." *N. F.*

Off. Prep.—Formaldehydum Cresolatum, *N. F.*

OVI ALBUMEN RECENS. N. F.

FRESH EGG ALBUMEN Ovi Album.

"The freshly separated liquid white, or albumen, of the recently laid egg of the hen, *Gallus domesticus* Temminck (Fam. *Phasianidæ*)." *N. F.*

Fresh Egg Albumen, Egg Albumen, Egg white; Eiweiss, *G.*

OVI VITELLUM RECENS. N. F.

FRESH EGG YOLK Ovi Vitel.

"The freshly separated yolk of the recently laid egg of the hen, *Gallus domesticus* Temminck (Fam. *Phasianidæ*)." *N. F.*

Fresh Egg Yolk, Egg Yolk; Dotter, Eidotter, *G.*; Tuorlo, *It.*

Off. Prep.—Glyceritum Vitelli, *N. F.*

OVUM GALLINACEUM. N. F.

FRESH EGG Ovum. Gallin.

"The recently laid egg of the hen, *Gallus domesticus,* Temminck (Fam. *Phasianidæ*)." *N. F.*

Egg, Hen's Egg; Ei, Hühnerei, *G.*; Oeuf, *F.*; Uovo, *It.*

The egg of the ordinary hen consists of an exterior covering, the shell; a white, semi-opaque membrane; the white; and the yolk.

The *shell*—*testa ovi* or *putamen ovi*—consists chiefly of calcium carbonate, with animal matter, and a minute proportion of calcium phosphate, magnesium carbonate, ferric oxide, and sulphur. When exposed to a high degree of heat in the open air, the carbon dioxide is driven off, the animal matter consumed, and the lime left nearly pure.

The *white* is a glairy, viscid liquid, contained in very delicate membranes, without odor or taste, readily soluble in water. It is 85 per cent. water, containing in solution approximately 12 per cent. of a protein belonging to the group of albumins (formerly the word album*e*n was applied to all the proteins of this group, but the tendency among modern writers has been to spell the generic word albumi*n* and to apply the word albume*n*, to the special form of albumin found in egg white); about 2.5 per cent. of a mucin-like substance, called *ovomucoid,* and traces of mineral salts. Albumen may be precipitated from solution without chemical alteration by saturation with certain neutral salts, such as ammonium sulphate. Many of the salts of the heavy metals such as gold chloride, lead subacetate, copper sulphate, mercuric chloride, etc., form insoluble compounds with albumen which leads to a precipitation. Tannic acid, acetic acid and most of the mineral acids if in sufficiently concentrated solutions likewise coagulate the egg albumen by chemical union. When heated above 75° C. the albumen is precipitated. This precipitation must be accompanied with some change in the chemical structure as the cooked albumen does not redissolve on cooling. Albumen is markedly lævo-rotatory, its specific power being about −35.5°. Exposed in thin layers to a current of air, it becomes solid, retaining its transparency and solubility in water. Dried white of egg occurs in the form of pale yellowish translucent scales soluble in eight parts of water. By coagulation it is rendered white, opaque, and insoluble. At a temperature of 100° C., one part of it renders opaque one thousand parts of water in which it has been dissolved. When kept in the fluid state it soon putrefies; but if carefully dried without coagulation it may be preserved unaltered a long time, and may be readily redissolved in water.

The *yolk* is inodorous, of a bland oily taste, and forms an opaque emulsion when agitated with water. By heat it is coagulated into a granular solid, which yields a fixed oil by expression. The constitution of the yolk is about as follows: water, 51.8 per cent.; vitellin, 15.8 per cent.; nuclein, 1.5 per cent.; palmitin, stearin, and olein, 20.3 per cent.; cholesterin, 0.4 per cent.; phosphoglyceric acid, 1.2 per cent.; lecithin, 7.2 per cent.; cerebrin, 0.3 per cent.; coloring matter, 0.5 per cent.; salts, 1.0 per cent. (König, *Nahrungs- und Genussmittel,* 180.)

Vitellin belongs to the class of proteins known as globulins which differ from the albumins in not being soluble in pure water, although they do dissolve in the presence of small amounts of certain neutral salts. From the solution they may be precipitated by saturation with magnesium or ammonium sulphate. The coloring matter is known as *lipochrome,* but of its true chemical structure we have no knowledge.

Cholesterin or *cholesterol* is a monatomic alcohol; the most recent investigations give it the formula of $C_{27}H_{45}OH$. Lecithin is described in Part II. It is said that the yolk may be kept for a considerable time without observable change by adding to it 5 per cent. of sodium sulphate, in powder or concentrated solution. Granules have been found, with the aid of the microscope, in the yellow of the egg, which are rendered blue by iodine, and have all the other properties of the starch granules.

Uses.—The value of eggs as a food-stuff cannot be here discussed in detail. It may be pointed out, however, that they are esteemed by many physicians not merely as a source of energy but for their large proportion of lecithin.

The yolk affords an excellent emulsifying agent and is widely employed in pharmacy for this purpose.

Under the name of *Glyconin* there has been employed in France for many years both for medicinal purposes and for those of the toilet, an emulsion made of glycerin and the yolk of egg. It is now recognized by the N. F. under the name of *Glyceritum Vitelli.* When these two substances are rubbed together, they unite to form a very intimate mixture, which does not separate. It has the consistence of honey, and forms an opaque emulsion with water. It may be preserved almost indefinitely. The usual proportions of the ingredients are four parts of the yolk of egg and five parts of pure glycerin.

The *white* of egg is used frequently for the clarification of liquids, which it effects by involving, during its coagulation, the undissolved particles, and rising with them to the surface, or subsiding. It has been recommended as an antidote for corrosive sublimate, copper sulphate, and other caustic poisons, with which it forms insoluble compounds; the practical value of this treatment of metallic poisons has been gravely questioned in recent years. It is sometimes also used for the suspension of insoluble substances in water, but is inferior for this purpose to the yolk, and even to mucilage of gum arabic. Agitated briskly with a lump of alum, it coagulates, at the same time dissolving a portion of the alum, and thus forming the so-called *alum curd,* which is used between folds of gauze over the eye, in some states of *ophthalmia.* It is also used in the official pepsin valuation.

OXYGENIUM. U. S.

OXYGEN Oxygen.

"Oxygen contains not less than 98 per cent. by volume of O. For convenience it is usually furnished in compressed form in metallic cylinders." *U. S.*

Oxygène, *Fr.;* Sauerstoff, *G.;* Ossigeno, *It.*

Oxygen was discovered about 1774 almost simultaneously by Priestley and Scheele. Both evolved it from metallic oxides or calces as they were called. Priestley called it *dephlogisticated air,* and Scheele called it *fire air,* it not then being recognized as a gaseous element, but was thought to be a kind of air. It is the most abundant of the elemental substances constituting, according to the calculations of some authorities, one-half of the weight of the earth and its atmosphere.

For experimental and laboratory purposes it is usually prepared by heating a mixture of potassium chlorate and manganese dioxide, the latter substance acting as a catalyst and remaining unchanged at the end of the operation, possessing the property of allowing the reaction $KClO_3 = KCl + O_3$ to take place at lower temperatures and without danger. Industrially it is usually prepared by the continuous process known as Brin's, in which BaO is heated in porcelain tubes to 500° C. in a current of carbon dioxide-free air. This produces BaO_2, which upon further heating to 800° C. again evolves the oxygen ($BaO_2 = BaO + O$). Upon lowering the temperature to 500° C. the absorption of oxygen again occurs and the alternate absorption and liberation may be repeated many times until, as is found in practice, the barium oxide loses its activity. Oxygen is also produced commercially from liquid air, taking advantage of the facts that the nitrogen is more volatile, and that the oxygen has a tendency to liquefy first.

G. Kassner has described a method for producing oxygen from the air by the use of a mixture of *sodium metaplumbate,* Na_3PbO_3, and *sodium manganate,* Na_2MnO_4. This combination, which is emerald-green in color, he calls *plumboxan.* The mixture is placed in a combustion tube and heated to between 430° C. and 450° C. Air freed from CO_2 is then passed through it and the oxygen is absorbed by the plumboxan while pure nitrogen passes through unchanged. Steam is then passed into the mass, which liberates the oxygen in an exceedingly pure condition. By alternately injecting air and steam, nitrogen and oxygen can be evolved in the order given indefinitely. The reactions, as given by the author, to account for the changes, are very complex. (*A. Pharm.*, ccli, p. 596.)

Oxygen has also been produced commercially by heating sodium permanganate or by liberating it from sodium peroxide by the action of water. Oxygen comes into commerce for laboratory or medicinal purposes compressed into steel cylinders provided with a valve and outlet tube.

Description and Physical Properties.—"A colorless, odorless, and tasteless gas. It supports combustion more readily than air. One volume of Oxygen dissolves in about 34 volumes of water and in about 3.6 volumes of alcohol, at 25° C.

"A glowing splinter of wood held in Oxygen bursts into flame.

"Pass 2000 cc. of the gas, measured under normal atmospheric pressure at about 25° C., through 100 cc. of barium hydroxide T.S. at a rate not exceeding 4000 cc. per hour: the turbidity produced, if any, is not greater than that produced by 1 cc. of a solution prepared by dissolving 0.2 Gm. of sodium bicarbonate in 100 cc. of freshly boiled and cooled distilled water (*carbon dioxide*). Pass 2000 cc. of Oxygen, under the conditions described above, through a mixture of 100 cc. of distilled water and 1 cc. of silver nitrate T.S.: no opalescence is produced (*halogens*). Pass 2000 cc. of Oxygen through 100 cc. of distilled water, colored with a few drops of litmus T.S., under the conditions described above: the color of the liquid is not changed (*acids* or *alkalies*). Pass 2000 cc. of Oxygen through 100 cc. of a freshly prepared starch-potassium iodide T.S.: the color of the liquid is not changed (*oxidizing substances*)." *U. S.*

Assay.—"Mix about 50 cc. of Oxygen, accurately measured in a calibrated tube, with

10 cc. of alkaline pyrogallol T.S.: not less than 98 per cent. by volume is absorbed, corresponding to not less than 98 per cent. by volume of O." *U. S.*

Uses.—Pure oxygen is so irritant locally that it is difficult to respire it; the statements sometimes made, however, that it is impossible to live in an atmosphere of pure oxygen do not seem to be well supported, at least as far as human beings are concerned. In normal health it is doubtful whether the respiring of pure oxygen has any marked effect upon the bodily processes except that which is due to the irritation of the mucous membrane. It must be remembered that the oxygen-carrying power of the blood is due to the chemical change of hemoglobin in the corpuscles, and enough oxygen is, ordinarily, absorbed by the lungs from the atmosphere to fully oxidize the hemoglobin, so that the blood leaving the lungs contains almost entirely oxyhemoglobin. The only increase in the amount of oxygen the blood will carry is in the relatively small proportion which is dissolved in the blood plasma. While this quantity may be notably increased by inhaling oxygen, in conditions of health its proportion to the oxygen in oxyhemoglobin is so small that it does not greatly affect oxidative processes in the body. On the other hand when the oxygen-carrying power of the blood is reduced—as, for instance, in *carbon monoxide poisoning* or *nitrite poisoning*—through chemical change in the hemoglobin, the amount of oxygen which may be dissolved by the plasma becomes a matter of practical importance and Haldane has experimentally shown (*J. P.*, 1897, xxi, p. 160) that animals will survive a supra-fatal dose of nitrites in an atmosphere of pure oxygen. Again in cyanotic conditions due to insufficiency of the circulation, as in cases of *heart failure,* the small increase in the oxygen of the blood may be sufficient to supply the need of the body and clinical improvement is often seen from the use of oxygen in such instances. In cases where the passage of air in and out of the lungs is obstructed, as in *asthma* or *pneumonia,* the use of oxygen is still more rational because of the small amount of air which comes in contact with the blood. Therefore in practically all cases in which cyanosis indicates a deficient amount of oxygen being carried by the blood, the inhalation of this gas is a reasonable procedure and clinically has in many cases given great relief. It must be remembered, however, that the oxygen does not act by stimulating any vital function, in the sense that strychnine or ammonium might, but it merely supplies a deficient necessity of life. The custom of having a patient inhale oxygen for ten or fifteen minutes at a time three or four times a day, is foolish; the inhalation of the gas must be kept up more or less continuously as long as the symptoms indicate the need of it.

OXYMEL. Br.

OXYMEL

"Acetic Acid, 100 *millilitres;* Distilled Water, 100 *millilitres;* Purified Honey, 500 *millilitres.* Mix." *Br.*

Oxymel Simplex; Mellitum; Mel Acetatum; Mellite de Vinaigre, Oxymelite simple, Acétomel, *Fr.;* Sauerhonig, *G.;* Oximiel simple, *Sp.*

"Specific gravity 1.27. 25 grammes require for neutralisation not less than 32 millilitres of *N/2 solution of sodium hydroxide.* The liquid obtained by mixing 25 grammes of Oxymel with 1 millilitre of *solution of lead subacetate,* diluting to 100 millilitres with *water,* adding 1 gramme of *animal charcoal,* and filtering until bright, has an *optical rotation* at 15.5° C. of not more than −3.9° in a tube 200 millimetres long." *Br.*

This mixture of honey and vinegar forms a pleasant addition to gargles, and is sometimes used as a vehicle of expectorant medicines and to impart flavor to drinks in febrile diseases.

Dose, from one to two fluidrachms (3.75–7.5 cc.).

OXYMEL SCILLÆ. Br.

OXYMEL OF SQUILL

"Vinegar of Squill, 200 *millilitres;* Purified Honey, 500 *millilitres.* Mix." *Br.*

Mellitum Scillæ; Mellite de Vinaigre Scillitique, Oxymel Scillitique, *Fr.;* Oxymel Scillæ, *P. G.;* Meerzwiebelhonig, *G.;* Ossimiele scillitico, *It.;* Oximiel escilitico, *Sp.*

"Specific gravity 1.29. 25 grammes require for neutralisation not less than 11.9 millilitres of *N/2 solution of sodium hydroxide.* The liquid obtained by mixing 25 grammes of Oxymel of Squill with 1 millilitre of *solution of lead subacetate,* diluting to 100 millilitres with *water,* adding 1 gramme of *animal charcoal,* and filtering until bright, has an *optical rotation* at 15.5° C. of not more than −3.9° in a tube 200 millimetres long." *Br.*

After a long vogue, this preparation fell into such neglect that it was abandoned by the Pharmacopœias. Its reintroduction, however, into the Br. Pharmacopœia indicates that it is still prescribed; it has also been introduced into the N. F. IV (see Part III). It has the virtues of syrup of squill, but no advantages. It is chiefly used as an expectorant in those states of the pulmonary organs in which the bronchial tubes are loaded with a viscid mucous of difficult expectoration.

Dose, from one-half to one fluidrachm (1.8–3.75 cc.). In large doses it is emetic, and as such is sometimes used in *infantile croup.*

OXYMEL URGINEÆ. Br.

OXYMEL OF URGINEA [Oxymel of Indian Squill]

"Vinegar of Urginea, 200 *millilitres;* Purified Honey, 500 *millilitres.* Mix." *Br.*

"Specific gravity 1.29. 25 grammes require for neutralisation not less than 11.9 millilitres of *N/2 solution of sodium hydroxide.* The liquid obtained by mixing 25 grammes of Oxymel of Urginea with 1 millilitre of *solution of lead subacetate,* diluting to 100 millilitres with *water,* adding 1 gramme of *animal charcoal,* and filtering until bright, has an *optical rotation* at 15.5° C. of not more than $-3.9°$ in a tube 200 millimetres long." *Br.*

This is a new preparation of the British Pharmacopœia, 1914. It is used for the same purposes as the *oxymel scillæ.*

Dose, from one-half to one fluidrachm (1.8–3.75 cc.).

PANCREATINUM. U. S.

PANCREATIN Pancreat.

"Pancreatin is a substance containing enzymes, principally amylopsin, trypsin, and steapsin, obtained from the fresh pancreas of the hog, *Sus scrofa* var. *domesticus* Gray (Fam. *Suidæ*) or of the ox, *Bos taurus* Linné (Fam. *Bovidæ*). It converts not less than 25 times its weight of starch into soluble carbohydrates and not less than 25 times its weight of casein into proteoses. Pancreatin of a higher digestive power may be brought to this standard by admixture with lactose." *U. S.*

Pancréatine médicinale, *Fr.;* Pancreatina, *Sp.*

The term "pancreatin" has been variously used for many different preparations from the pancreatic gland, and has long been popularly employed for the purpose of distinguishing preparations more or less of the nature of extracts made from the gland. The *pancreatic juice* is an albuminous, transparent liquid, odorless, alkaline, and containing about eight per cent. of organic matter. It is now generally recognized that there are present in the pancreatin secretion three distinct enzymes: *trypsin,* whose function it is to convert albuminous matters into peptone, and probably also peptones into their aminoacids; *amylopsin* or *amylase,* a ferment closely allied if not identical with the ptyalin of the saliva, which hydrolizes starch into maltose and dextrin; and *steapsin* (*lipase, pialyn*), which has the power of splitting up fats into glycerin and fatty acids. Besides these ferments there is apparently present also another substance which has the property of curdling milk. Because of its fat splitting properties the pancreatic juice has a strong emulsifying effect, the viscous agent being the soap formed through the splitting of the fat. The activity of the lipase is greatly increased by the presence of bile. This emulsifying action takes place very rapidly; according to Rachford (*J. Chem. S.,* 1891, 948) a spontaneous emulsion may be formed in two minutes at room temperature. The proteolytic enzyme of the pancreas can be separated to a large extent from the other digestive ferments and various manufacturing pharmacists have placed such preparations on the market under the names of *trypsin* (see *N. N. R.,* 1924). These are not, however, the pure enzyme but contain varying proportions of inert protein. The proteolytic power of some of these preparations far exceeds the pharmacopœial requirements; but they are much less potent than the same amount of pepsin.

All of the pancreatic ferments are active in neutral or mildly alkaline media, but the most favorable reaction is not the same for all of them, thus trypsin is best with an alkalinity corresponding to about 1 per cent. of sodium carbonate, but amylopsin acts most rapidly in the presence of 0.01 per cent. of hydrochloric acid, and the action of the fat splitting ferment is also accelerated by a faintly acid reaction.

The pancreatin of the U. S. Pharmacopœia contains all of these ferments, with more or less extraneous matter.

Various methods of manufacturing pancreatic extracts are employed. Water readily dissolves all the ferments and the French Codex directs that pancreas gland purified by separating foreign matter is to be cut into small pieces, macerated in chloroform water, then expressed, the liquid filtered and rapidly evaporated at a temperature not exceeding 45° C. Choay (*P. J.,* 1898, 505) criticizes the temperature for evaporation and recommends evaporation *in vacuo* at 38° C. Precipitation by the use of strong alcohol is the method used for purification. Biernacki (*A. J. P.,* 1892) previously stated that digestive ferments require for their efficient action a temperature little over that of the human body, 39°. A useful and permanent extract may also be obtained by exhausting the finely divided pancreas with water containing about 2 per cent. of boric acid and 1 per cent. of borax. (Allen, *Com. Org. Anal.,* 2d ed., vol. iv, 354.) The mixed pancreatic enzymes may also be extracted by means of glycerin which gives an active extract which may be preserved indefinitely, but one which cannot be reduced to the dry state. For this purpose the gland is finely minced, rubbed up with some clean sand, shaken with from 10 to 20 parts of glycerin and allowed to stand for about two weeks, then filtered. Another method of extracting its activity is by macerating the minced gland with four times its weight of 25 per cent. alcohol for four or five days. If the pancreas be allowed to stand for two or three days before extracting the resulting pancreatin will be richer in the trypsin and amylopsin, but will have very little fat splitting powers. Where it is desirable to make a pancreatin containing active lipase it should be made from the fresh gland.

Description and Physical Properties.—"A cream colored, amorphous powder, having a faint, characteristic, but not offensive odor. Pancreatin is slowly and incompletely soluble in water; insoluble in alcohol. Pancreatin changes proteins into proteoses and derived substances, and converts starch into dextrins and sugars. Its greatest activities are in neutral or faintly alkaline media; more than traces of mineral acids or large amounts of alkali hydroxides render it inert. An excess of alkali carbonates also inhibits its action.

"Introduce 2 Gm. of Pancreatin into a flask of about 50 cc. capacity, add 20 cc. of ether, stopper, and set it aside for several hours, mixing by rotating at frequent intervals. Decant the supernatant ether by means of a guiding rod into a plain filter of about 7 cm. diameter, previously moistened with ether, and collect the filtrate in a tared beaker. To the residue remaining in the flask add a further portion of 10 cc. of ether, proceeding as directed before, then a third portion of 10 cc. of ether, and transfer the ether and the remainder of the pancreatin to the filter. Allow to drain, evaporate the ether spontaneously, and dry the beaker and residue to constant weight at 100° C.: the residue weighs not more than 0.06 Gm. (*fat*).

"**Assay for Starch Digestive Power.**—Shake 10 Gm. or more of powdered potato starch with about 10 times its weight of cold distilled water, and, after draining the mixture on a filter, wash it with the same quantity of distilled water. Place the washed starch at once in an air bath, and maintain a temperature of about 50° C. until the starch is sensibly dry. Reduce it to a fine powder, and place it in a well-stoppered bottle. Determine the percentage of water remaining in the starch by drying about 0.5 Gm. of it in an air bath, gradually raising the temperature to 120° C. and maintaining it at that temperature for four hours. Of the washed and partially dried starch, mix a quantity equivalent to 7.5 Gm. of dry starch in a 400 cc. beaker with 10 cc. of cold distilled water, add 190 cc. of boiling distilled water, and boil the mixture gently with constant stirring for five minutes or until a translucent, uniform paste is obtained. Replace the water lost by evaporation, and cool the paste to 40° C. in a water bath previously adjusted to this temperature, and add a solution of 0.3 Gm. of Pancreatin in 10 cc. of distilled water, just previously made at 40° C. Mix well, and maintain the same temperature for exactly five minutes, when a thin, nearly clear liquid is produced. At once add 0.1 cc. of this liquid to a previously made mixture of 0.2 cc. of tenth-normal iodine and 60 cc. of distilled water. No blue, red or violet color is produced.

"**Assay for Casein Digestive Power.**—Place 0.1 Gm. of finely powdered casein in a 50 cc. volumetric flask, add 30 cc. of distilled water, and shake well to bring the casein into suspension. Add exactly 1 cc. of tenth-normal sodium hydroxide, and heat the mixture at 40° C. until the casein is completely dissolved, which should not require more than thirty minutes. Cool, add sufficient distilled water to make 50 cc., and mix well. Dissolve 0.1 Gm. of Pancreatin in 500 cc. of distiled water. Mix 1 cc. of glacial acetic acid with 9 cc. of distilled water and 10 cc. of alcohol. Place 5 cc. of the casein solution in a test tube, add to it 2 cc. of the well-shaken Pancreatin solution and 3 cc. of distilled water, and mix by gentle agitation. Immediately immerse the test tube in a water bath at 40° C., and keep it at this temperature for one hour. Then remove from the bath, and add 3 drops of the acetic acid mixture. No precipitate is produced.

"Preserve in well-closed containers." *U. S.*

Uses.—Pancreatin was first used in medicine on account of its emulsifying properties. Horace Dobell, noticing that consumptives are very likely to have a dislike for fat, conceived the idea that this was due to lack of pancreatic digestion, and administered an emulsion made with the fat of beef stirred in milk with the pancreatic juice of the pig. A little later, pancreatic preparations of cod liver oil were prepared, and still have much vogue. Besides this employment, pancreatin has two distinct uses; first, as a ferment to be administered in dyspepsia; second, as a valuable means for the predigestion of food. It is probable that when given internally pancreatin may escape from the stomach into the intestines and the combination of pepsin and pancreatin in *dyspepsia* is not unphilosophical.

Any attempt to make a practical evaluation must bear in mind certain elementary facts: (1) The tryptic ferment is most active in a feeble alkaline medium. It exerts, however, some digestive power in neutral solutions but the presence of free acids not only hinders the ferment action of trypsin but actually destroys the enzyme itself. (See Long and Hull, *J. Am. C. S.*, 1916, xxxviii, and 1917, xxxix, p. 162.) (2) Trypsin is destroyed by artificial gastric juice but Long and Hull have shown that it may resist peptic digestion for considerable time, provided there be enough other protein present to unite with the free hydrochloric acid. (3) Amylopsin acts well in a neutral or faintly acid medium. According to Meltzer's observations the optimum reaction is equivalent to 0.01 per cent. HCl (*In. Dis.*, 1894.) (4) The fat splitting enzyme, steapsin, is the least stable of all pancreatic ferments and is especially susceptible to the action of acids. From the above facts it is manifest that the digestive powers of pancreatin in the stomach must be very limited because of the acidity of the gastric secretions. On the other hand, in the early stages of gastric digestion before the acidity has fully developed, there may be some digestion of starches and perhaps also of proteins by the pancreatic ferment. This, however, cannot continue long and the pancreatic ferments are liable themselves to be eventually destroyed by the rising tide of acid pepsin.

In the predigestion of food by pancreatin, five grains of commercial pancreatin of good quality, with twenty grains of sodium bicarbonate, in an ounce of warm water, may be added to a pint of milk, and kept at the temperature of 43.3° C. for from twenty minutes to an hour. As the thoroughly peptonized or predigested food is very bitter, when the milk is to be given by the mouth it is better to arrest the peptonizing process by boiling the milk after digestion has continued for twenty to thirty minutes, unless the milk can be used at once. Nutritive enemata should be thoroughly pancreatized.

Trypsin has been used in medicine in a variety of conditions. Beer (*Lancet*, 1905) has recommended it as a local treatment for *inoperable cancers,* Schiller (*K. T. W.*, 1910) in the treatment of *tuberculous abscesses,* and Lamballe (*N. Y. M. R.*, 1913) asserts that the intramuscular injection of solutions of trypsin have curative value in *malaria.*

For other uses of the pancreas and its peculiar hormone insulin, see under *Organotherapy,* Part II.

Dose, of pancreatin, eight to fifteen grains (0.5–1.0 Gm.).

Off. Prep.—Liquor Pancreatis, *Br.;* Liquor Pancreatini, *N. F.;* Pulvis Pancreatini Compositus, *N. F.*

PARAFFINUM. U. S. (Br.)

PARAFFIN Paraff.

"A purified mixture of solid hydrocarbons, obtained from petroleum." *U. S.* "Hard Paraffin is a mixture of solid hydrocarbons." *Br.*

Paraffinum Durum, *Br.;* Hard Paraffin; Paraffin Wax; Solid Paraffin; Ceresinum; Paraffinum solidum, *P. G.;* Festes Paraffin, Gereinigtes Erdwachs, *G.;* Parafina, *Sp.*

The name *paraffin,* often spelled *paraffine,* was originally bestowed by Baron von Reichenbach upon a waxy substance obtained through the destructive distillation of wood. He derived it from *parum affinis,* and thus intended to indicate its very neutral character. The name is now popularly applied to a solid white diaphanous substance, resembling white wax, which is procured from petroleum or bituminous shales by distillation, or from ozokerite by purification. (See *Ozokerite, Ceresin,* in Part II.) In the manufacture from petroleum, as carried out in the United States, the residuum from the distillation of crude petroleum for illuminating oil is taken. This is redistilled from what are called "tar stills," in which the distillation is pushed until only coke remains. The paraffin oil distillate obtained in this way is treated with from 4 to 5 per cent. of sulphuric acid, washed, and treated with caustic soda, the mixture being kept liquid by the aid of steam coils. After settling, the paraffin oil goes to the "chill-rooms," where, by the aid of the refrigerating machines the whole mass is brought to a semi-solid condition. This is subjected to powerful pressure, and the refined heavy oil which drains off is collected as lubricating oil. Its specific gravity should be about 32° B. The press cake may be broken up, melted, and allowed to solidify, and then submitted to still greater pressure at a higher temperature 21.1° C. than before, when the product is known as "refined wax." To convert it into block paraffin it must be washed with petroleum benzin, pressed, melted, and filtered through bone black or other medium, when it solidifies in a hard, translucent, colorless condition.

Description and Physical Properties.—Paraffin, in its pure condition, is a white, waxy, inodorous, tasteless substance, harder than tallow, softer than wax, with a specific gravity of 0.900. Its melting point is variable, depending somewhat upon its origin; it ranges between 43° and 65° C. An ultimate analysis yields, on the average, carbon 85 per cent. and hydrogen 15 per cent. It is indifferent to most acids and alkalies, and can be distilled unchanged with strong sulphuric acid. Warm alcohol, ether, oil of turpentine, olive oil, benzene, chloroform, and carbon disulphide dissolve it readily. It can be mixed in all proportions with wax, stearin, palmitin, and resin. As stearin is less soluble in benzene than paraffin, Vogel proposes this reaction as a method for detecting the adulteration of paraffin with stearin. (Joy.)

"A colorless, or white, more or less translucent mass, frequently showing a crystalline structure. It is without odor or taste, and is slightly greasy to the touch. Paraffin is insoluble in water and in alcohol; slightly soluble in dehydrated alcohol; freely soluble in chloroform, ether, benzene, petroleum benzin, carbon disulphide, volatile oils, and in most warm fixed oils.

"Specific gravity: about 0.900 at 25° C. It melts between 50° and 57° C. When strongly heated, Paraffin ignites, burns with a luminous flame, and deposits carbon. Heat about 0.5 Gm. of Paraffin in a dry test tube with an equal weight of sulphur: the mixture becomes black from separated carbon, and hydrogen sulphide gas is evolved. Paraffin is not acted upon or colored by concentrated sulphuric or nitric acid in the cold. Shake melted Paraffin with an equal volume of hot alcohol; the separated alcohol does not redden moistened blue litmus paper (*acids*)." *U. S.*

The Br. Pharm. describes it as "colorless, crystalline, more or less translucent; wax-like, slightly greasy to the touch. No odor or taste. Melting point 50° to 60° C. 5 millilitres of *alcohol* (90 per cent.) shaken with 5 grammes of the melted Paraffin are not acid to *litmus.* 5 grammes, when heated, burn with a luminous flame, leaving no appreciable ash." *Br.*

The fact that solid paraffin wax is essentially made up of a mixture of hydrocarbons of the series C_nH_{2n+2} was established by Gill and Meusel, who studied the action of bromine upon it. The fact that when paraffin wax is oxidized by concentrated nitric acid or by chromium trioxide mixture we obtain *paraffinic acid,* $C_{24}H_{48}O_2$, and *cerotic acid,* $C_{27}H_{54}O_2$, shows that it is essentially made up of hydrocarbons between $C_{24}H_{50}$ and $C_{27}H_{56}$. For *Soft Paraffin,* or *Paraffinum Molle,* see *Petrolatum.*

Uses.—In the arts paraffin is used for many purposes, especially in the manufacture of candles, and sealing various vessels to exclude air. Lemons and eggs coated with paraffin may be kept for long periods of time without decomposition. It is also valuable to saturate paper, rendering it impervious to moisture. In pharmacy it is used chiefly to give stiffness to ointments. It was at one time employed in cosmetic surgery by injecting melted paraffin for filling out undesirable hollows. The treatment resulted in a number of cases, however, in extensive sloughing and has been largely abandoned.

For the use of paraffin as a protective dressing for burns see *Ambrine,* Part II.

Off. Prep.—Curatio Paraffini, *N. F.*

PARAFFINUM CHLORINATUM. U. S.

CHLORINATED PARAFFIN

Paraff. Chlorinat. [Chlorcosane]

"A chlorinated paraffin." *U. S.*

This preparation was suggested by Dakin and Dunham (*B. M. J.,* 1918) as a solvent for dichloramine. They made it by passing chlorine gas into melted paraffin, maintaining the temperature at 125° C. to 140° C., until the liquid increased in weight from about 50 per cent. This liquid, still warm, is then agitated with 5 per cent. of its weight of dry sodium carbonate and filtered. It contains from 30 to 40 per cent. of chlorine which is so firmly bound that it can scarcely be removed with boiling solutions of the alkalies; it yields its chlorine, however, when boiled with aniline.

Description and Physical Properties.—"A light yellow to light amber, clear, thick, oily liquid. It is odorless, and is stable in the air. Chlorinated Paraffin is insoluble in water; slightly soluble in alcohol, but miscible with benzene, carbon tetrachloride, chloroform, and with ether.

"Specific gravity: 1.00 to 1.07 at 25° C. Boil 5 drops of Chlorinated Paraffin with 10 cc. of alcoholic potassium hydroxide T.S. under a reflux condenser for thirty minutes, cool, dilute with 10 cc. of distilled water, and acidulate with diluted nitric acid: the liquid becomes turbid from the separation of small, oily drops. Shake the mixture with an equal volume of ether, allow the liquids to separate, draw off the clear aqueous layer, and add to it a few cc. of silver nitrate T. S.: a white precipitate is formed.

"Ash: not more than 0.1 per cent. Shake about 5 Gm. of Chlorinated Paraffin with 25 cc. of warm distilled water for five minutes, and filter through a filter paper moistened with distilled water: the filtrate is neutral to litmus paper (*acids or alkalies*), and on adding a few drops each of potassium iodide T.S. and of starch T.S. to 5 cc. of the filtrate, no blue color is produced (*free chlorine*). Another 5 cc. portion of the filtrate shows no more *chloride* than corresponds to 0.05 cc. of fiftieth-normal hydrochloric acid. Dissolve 10 Gm. of Chlorinated Paraffin in 10 cc. of carbon tetrachloride in a 50 cc. volumetric flask, dissolve in this solution about 0.5 Gm. of powdered dichloramine, accurately weighed, and allow the mixture to stand at 40° C. for four hours protected from light. Cool, and dilute with sufficient carbon tetrachloride to measure 50 cc. Transfer 10 cc. of this dilution to a glass-stoppered flask, add 10 cc. of glacial acetic acid and 5 cc. of potassium iodide T.S., and tightly stopper the flask. Allow to stand for ten minutes, add 25 cc. of distilled water, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Make a blank test with the same quantity of the same dichloramine and the other reagents, but omitting the Chlorinated Paraffin and using sufficient carbon tetrachloride to measure 50 cc. The difference between the amount of tenth-normal sodium thiosulphate consumed in the blank test and that required for the original test is not greater than 0.6 cc. (*completeness of chlorination*)." *U. S.*

Uses.—Chlorcosane is employed solely as a means of applying dichloramine, the latter being rapidly decomposed by liquid petrolatum. It is too viscid to be readily sprayed with an atomizer; when used for this purpose it may be thinned by the addition of carbon tetrachloride or eucalyptol.

PARAFORMALDEHYDUM. U. S.

PARAFORMALDEHYDE Paraform. [Paraform, Trioxymethylene]

"Paraformaldehyde contains not less than 95 per cent. of $(HCHO)_3$." *U. S.*

Triformal; Trioxymethylenum; Formaldehydum Polymerisatum.

Paraformaldehyde is always produced to a greater or lesser extent when solutions of formaldehyde are allowed to evaporate. The change from the ordinary into the polymeric form also takes place at low temperatures, especially when the solution is free from methyl alcohol. This is the way in which it is now produced commercially.

Description and Physical Properties.—"White friable masses, or a white powder, having a slight odor of formaldehyde. Paraformaldehyde is very slowly soluble in cold water, more readily soluble in hot water with the formation of formaldehyde; insoluble in alcohol and in ether; soluble in solutions of fixed alkali hydroxides. Paraformaldehyde, when heated, is partly converted into formaldehyde and partly sublimed unchanged.

"Add 10 drops of sulphuric acid to a mixture of about 0.01 Gm. each of Paraformaldehyde and morphine sulphate: a violet color is produced. Gently warm about 0.02 Gm. of Paraformaldehyde with 5 cc. of sulphuric acid in which about 0.1 Gm. of salicylic acid has been dissolved: a deep red color develops.

"Shake 0.5 Gm. of Paraformaldehyde, finely powdered, with 10 cc. of distilled water: the water remains neutral to litmus paper. Ash: not more than 0.1 per cent.

"**Assay.**—Mix about 1 Gm. of Paraformaldehyde, finely powdered and accurately weighed, with 50 cc. of normal sodium hydroxide in a 250 cc. flask, and add immediately, but slowly, through a small funnel, 50 cc. of solution of hydrogen dioxide which has been previously rendered neutral to litmus T.S. with sodium hydroxide T.S. When the reaction has ceased and the foam subsided, rinse the funnel and the sides of the flask with distilled water, allow the liquid to stand for half an hour, and then determine the excess of alkali with normal sulphuric acid, using litmus T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.03002 Gm. of $(HCHO)_3$.

"Preserve in well-closed containers, in a cool place, protected from light." *U. S.*

Uses.—Although trioxymethylene appears to possess some antibacterial properties *per se,* it is used chiefly as a source for the generation of formaldehyde. The especial utility of the substance for this purpose lies in the fact that by simply heating it is converted into the active gas. Special lamps are upon the market in which a small alcohol flame serves to at once depolymerize the paraform while the moisture from the combustion of the alcohol increases the activity of the formaldehyde. Rideal (*Disinfection and the Preservation of Food,* 1903, p. 309) finds that 10 Gm. of paraformaldehyde per thousand cubic feet of air space in a properly sealed room, is sufficient to destroy the vitality of most pathogenic organisms, but will not certainly kill those enclosed in bedding or similarly protected. The room should be left closed for twenty-four hours. Because of the comparative cost, however, this method is not to be recommended for disinfection of large spaces, but is very convenient for the sterilization of various surgical materials which might be injured by boiling. For this purpose small airtight chambers are employed in which from 1 to 2 Gm. (15–30 grains) for each cubic yard of air space is evaporated.

Paraformaldehyde is also occasionally used internally as a gastro-intestinal disinfectant. Pauchet and Sourdat (*B. A. M.,* 1914) highly laud gauze impregnated with paraform for the treatment of gunshot and other *wounds.* For the preparation of this the gauze is placed in a tin box with a few tablets of trioxymethylene and the box closed, and then put in a warm place, about 50° C. for an hour. It is also used externally as a caustic, for the destruction of *warts,* in 10 per cent. solution. Under the trade name of *formoforin* a mixture of paraform and talc has been employed in Germany for various forms of *hyperidrosis.*

Dose, five to fifteen grains (0.3–1.0 Gm.).

PARALDEHYDUM. U. S., Br.

PARALDEHYDE Paraldehyd. [Paracetaldehyde]

"A polymer $[(CH_3CHO)_3]$ of acetaldehyde." *U. S.* "Paraldehyde, $C_6H_{12}O_3$, is a product of the polymerisation of acetaldehyde." *Br.*

Paraldéhyde, Elaldéhyde, *Fr. Cod.;* Paraldehydum, *P. G.;* Paraldehyd, *G.;* Paraldehido, *Sp.*

Small quantities of acids like hydrochloric and sulphuric, and of certain salts like zinc chloride, convert ethyl, or acetic, aldehyde at ordinary temperatures into its polymer paraldehyde. Commercially it is prepared by the action of hydrochloric upon *acetaldehyde* until the resulting product is no longer soluble in its own volume of water, and then purifying by redistillation and freezing and expressing.

Description and Physical Properties.—"A colorless, transparent liquid. It has a strong, characteristic, not unpleasant or pungent odor, but a disagreeable taste. One cc. of Paraldehyde is soluble in about 8 cc. of water at 25° C. One cc. is soluble in 17 cc. of boiling water. It is miscible with alcohol, chloroform, ether, and with volatile oils.

"Specific gravity: about 0.990 at 25° C. It boils between 120° and 125° C. Congealing point: not below 9° C. When heated with a small quantity of sulphuric acid, Paraldehyde is converted into acetaldehyde, recognizable by its odor.

"Heat 5 cc. of Paraldehyde on a water bath: no disagreeable odor is noticeable as the last portions evaporate (*impurities derived from fusel oil*) and not more than 0.003 Gm. of residue remains. One cc. of Paraldehyde forms with 10 cc. of distilled water at 25° C., a clear solution, free from oily drops (*amyl alcohol*). A 5 cc. portion of this solution, acidulated with a drop of hydrochloric acid, yields no turbidity on the addition of 3 drops of barium chloride T.S. (*sulphate*). Another 5 cc. portion, acidulated with 1 drop of nitric acid, yields no opalescence at once on the addition of three drops of silver nitrate T.S. (*chloride*). A mixture of 6 cc. of Paraldehyde and 8 cc. of alcohol with 1 drop of phenolphthalein T.S. acquires a pink color upon the addition of 0.5 cc. of normal sodium hydroxide (*free acid*). Shake 5 cc. of Paraldehyde with 5 cc. of potassium hydroxide T.S. and allow the mixture to stand at 20° C.: the aqueous layer is not colored yellow or brown within thirty minutes (*acetaldehyde*).

"Preserve in well-closed containers, in a cool place, protected from light." *U. S.*

The British Pharmacopœia gives the following properties and tests: "A clear, colorless liquid. Characteristic, ethereal odor; taste acrid, afterwards cool. Soluble in 9 parts of *water;* less soluble in hot *water.* Miscible in all proportions with *alcohol* (90 per cent.), and with *ether.* Aqueous solution neutral or only slightly acid to *litmus.* Specific gravity 0.998 to 1.000. Solidifies at a low temperature; melting point not under 10° C. Not more than 5 per cent. distils under 123° C., and the remainder distils between 123° and 125° C. When 5 millilitres are shaken with 5 millilitres of *solution of sodium hydroxide* and allowed to separate, the aqueous layer does not exhibit more than a faint yellow coloration within one hour (limit of acetaldehyde). An aqueous solution (1 in 10) yields no characteristic *reactions* for chlorides or for sulphates." *Br.*

Uses.—In moderate doses paraldehyde causes, both in man and the lower animals, sleep which is indistinguishable from natural sleep and is unaccompanied with any marked change in the circulation, respiration, or sensibility. After large quantities the sleep becomes of a more comatose character, there is diminution of reflex activity and considerable slowing of the respiration, the circulation, however, being scarcely affected. It is asserted by Quinquaud that after fatal doses methemoglobin appears in the blood. Death is alleged to have been produced by four ounces in man, but Probst reports a case in which five ounces were taken within a period of sixty hours, causing a profound coma, lividity, and slight fall of bodily temperature, but with no pronounced circulatory disturbances and recovery on the seventh day. It is eliminated partly through the urine and partly with the breath in each of which it may be detected by its odor.

Paraldehyde is a promptly acting somnifacient of moderate power, useful in those types of *sleeplessness* which are not dependent upon pain. Its effects are generally manifest within fifteen to thirty minutes and last two or three hours. Its chief disadvantages are its occasional tendency to cause gastric disturbance and the unpleasant odor which it imparts to the breath. It has also been recommended for the relief of *asthma.*

Dose, one-half to one and one-half fluidrachms (1.8–5.5 cc.).

PAREIRA. N. F.

PAREIRA Pareir. [Pareira Brava]

"Pareira is the dried root of *Chondodendron tomentosum* Ruiz et Pavon (Fam. *Menispermaceæ*). Pareira contains not more than 5 per cent. of its stems or more than 2 per cent. of other foreign organic matter." *N. F.*

Pareira Brava, Pareiræ Radix, *Br. Add.;* Pareira Root.

This root was for a long time attributed to the *Cissampelos Pareira* L., but Hanbury in 1873 demonstrated its true source. *Chondrodendron tomentosum* is a climbing, woody vine, which often attains a considerable height, and is remarkable for the size of its leaves. These are about a foot long, broadly ovate or rounded, slightly cordate, with a smooth upper surface, and on the under surface, between the veins, covered with a fine close wool of an ashy hue. The racemose fruits are of the size of large grapes, oval and black. This plant inhabits both Brazil and Peru where it thrives in a wild state. The roots are dug up at various seasons of the year, cleaned, cut into transverse segments and dried. The commercial supplies come chiefly from Rio de Janeiro and Bahia, Brazil.

Description and Physical Properties.—"*Unground Pareira.*—Nearly cylindrical, more or less tortuous, of variable length and from 1 to 6 cm. in diameter; externally brownish black with transversed ridges on knot-like projections, occasionally fissured and longitudinally wrinkled or even furrowed; hard, heavy and tough; when freshly cut having a waxy luster; the transverse surfaces exhibiting several successive concentric zones of fibro-vascular bundles, each from 2 to 4 mm. in width with crenated borders and separated by distinct zones of parenchyma and stone cells, the zones radially marked by prominent medullary rays. Stems deeply furrowed, grayish in color, usually covered with foliaceous patches of lichens; internally grayish yellow, with a prominent development of wood with a tendency to separate fibro-vascular bundles and without a waxy luster. Odor slight; taste very bitter.

"*Powdered Pareira.*—Dark brown, containing numerous starch grains and a few woody fragments; starch grains mostly simple, occasionally unequally 2- to 4-compound, the individual grains ellipsoidal or oblong, 0.005 to 0.030 mm. in diameter and occasionally with central clefts or irregular markings; fragments with large, wide tracheæ, the walls with numerous slit-like pores and associated with long, thick-walled, strongly lignified, porous wood fibers; stone cells in small groups, with thick porous walls and in form resembling those of the fruits and seeds; fragments of starch-bearing parenchyma; the cells of the root being thick-walled, strongly lignified and with large longitudinal, elliptical pores: occasional fragments of blackish brown cork." *N. F.*

Recent adulterants and substitutes of Pareira have consisted of the roots and stems of *Cissampelos Pareira* L. (Fam. *Menispermaceæ*) and the stems of the *Chondrodendron tomentosum* Ruizet Pavon. The roots of *Cissampelos Pareira* are dark brown externally, light brown internally, are devoid of a waxy luster on their cut surfaces and show but one circle of fibrovascular bundles. The stems of this plant are usually less than an inch in diameter, show spirally furrowed or wrinkled, light brown bark, a coarse fibrous fracture and but one circle of bundles. Both root and stem are bitter but not astringent. The stems of true pareira may be distinguished by having a distinct pith, concentrically arranged bundles often separated from adjacent tissue, the absence of a waxy luster on their cut surfaces and by often possessing foliaceous lichens with black apothecia on their outer surface. The *Chondrodendron platyphyllum* Miers appears to have been, at times, substituted for the genuine root.

Constituents.—The chemistry of pareira is much confused on account of the uncertainty of the botanical origin of the roots which various chemists have investigated. Wiggers in 1838 found in the *Cissampelos Pareira* an alkaloid which he called *pelosine.* Flückiger (*P. J.,* 1870, xi, 192) subsequently showed that pelosine was identical with *bebeerine* of nectandra (see *Bebeeru bark,* Part II) and with the alkaloid that he had previously found in *Chondrodendron tomentosum.*

The substance known commercially as bebeerine sulphate, and said to be obtained from pareira, according to Scholtz (*A. Pharm.,* 1914, cclii, p. 513) is really a mixture of at least five alkaloids, bebeerine, *iso-bebeerine,* beta-bebeerine, bebeerine-b and *chondrodine.* The name *chondrodendine* has also been suggested for bebeerine. Ringer and Brooke (*A. J. P.,* 1892, 255) proved that the true chondrodendron root contained a larger quantity of both alkaloidal and extractive principles than do the substitutes. (See also Dohme's paper, *D. C.,* 1896, 296.)

Uses.—Pareira is supposed to have a diuretic effect and to act as an antiseptic in the bladder. It is chiefly employed for the relief of *chronic inflammations of the urinary passages.* In Brazil it is used in the cure of the *bites of poisonous serpents,*—a vinous infusion of the root being taken internally, while the bruised leaves of the plant are applied to the wound.

Dose, thirty to sixty grains (2.0–3.9 Gm.).

Off. Prep.—Fluidextractum Pareiræ, *N. F.*

PASSIFLORA. N. F.

PASSION FLOWER Passiflor. [Passion Vine]

"Passion Flower is the dried flowering and fruiting top of *Passiflora incarnata* Linné (Fam. *Passifloraceæ*). Passion Flower contains not more than 5 per cent. of stems over 8 mm. in diameter or other foreign matter." *N. F.*

Wild Passion Flower; May-pop.

The *Passiflora incarnata* is a climbing perennial herb, indigenous to the southern United States, with broadly cordate-ovate, palmately three-lobed leaves and solitary large flowers, the calyx bearing in its throat five white petals and a fringe, called the corona, which is of a purplish or pinkish color. The fruit is a yellowish berry about the size of a hen's egg. The whole of the overground portions are employed. Commercial supplies of this drug come from North Carolina and Virginia.

Description and Physical Properties.—"*Unground Passion Flower.*—Stems glabrous or slightly pubescent above, striate, from 6 to 8 mm. in diameter, of variable length, woody, hollow, the cavity about one-half the diameter; bark very thin, greenish or purplish; wood very porous and bordered on the inner side by a thin layer of pith; fracture of the wood uneven, of the stem smooth, of the bark coarsely fibrous. Leaves more or less broken, rather thick, glabrous or often pubescent, when entire nearly orbicular in outline, base cordate, deeply three- to five-lobed, lobes ovate, finely serrate, petioles from 1 to 5 cm. in length, with two glands near the apex. Tendrils numerous and closely coiled. Flowers solitary, axillary, peduncles as long as the petioles, usually three bracted; calyx cup-shaped, with four to five lobes; lobes linear, imbricated, cuspidate, corona of the fresh flowers purplish; petals four to five, yellow; ovary oblong, stalked; stamens monadelphous in a tube about the stalk of the ovary, separated above, anthers narrow, versatile. Fruit from 4 to 5 cm. in length, an ovoid, many-seeded berry; externally green or yellow, shriveled and wrinkled; seeds flat, ovate, yellowish to brown arilled. Odor and taste slight.

"*Powdered Passion Flower.*—Light green; numerous thin-walled non-glandular hairs, 1- to several celled, up to about 0.450 mm. in length; numerous fragments of stem tissue composed of pith and wood parenchyma, tracheæ with spiral and reticulate markings or simple pores and fibers; fragments of leaf tissue composed of chlorenchyma and epidermal cells with stomata from 0.020 to 0.035 mm. in length; calcium oxalate rosettes from 0.010 to 0.030 mm. in diameter." *N. F.*

We have no knowledge of the nature of the active principle of this drug.

Uses.—The passion-flower was introduced into medicine about 1840 by Doctor Phares of Mississippi. It is used as a nerve sedative to allay general *restlessness,* to relieve *insomnia,* and in the relief of certain types of *convulsions* and spasmodic disorders. It is also attributed with anodyne properties and is used in the treatment of various *neuralgias.* While there is considerable evidence that this drug possesses some therapeutic virtue, it has not been carefully studied. J. Ott (*Medical Bulletin,* Dec., 1898) finds that it is a depressant to the motor side of the spinal cord, but increases the rate of the respiration, and that it has very little effect upon the circulation, only temporarily reducing the arterial pressure.

Dose, three to ten grains (0.2–0.65 Gm.).

Off. Prep.—Tinctura Passifloræ, *N. F.*

PELLETIERINÆ TANNAS. U. S., Br.

PELLETIERINE TANNATE Pellet. Tann.

"A mixture of the tannates of the several alkaloids obtained from pomegranate." *U. S.* "Pelletierine Tannate is a mixture of the tannates of the alkaloids obtained from the bark of the root and stem of Punica Granatum, *Linn.*" *Br.*

Pelletierinum Tannicum, Punicinum Tannicum; Punicine Tannate; Tannate de Pelletiérine, *Fr.;* Gerbsaures Pelletierin, Punicin, *G.*

Preparation.—This preparation is a mixture of the various alkaloids of pomegranate bark (see *Granatum*). The bark is ground, and mixed with milk of lime; the mixture is percolated with water, the percolate shaken with chloroform, and the separated chloroformic liquid which contains in solution the mixed alkaloids, is treated with a weak solution of sulphuric acid; upon the addition of a solution of tannic acid to the neutral solution of the sulphates, tannates are precipitated; these are washed and dried.

Description and Physical Properties.—" A light yellow, odorless, amorphous powder, having an astringent taste. One Gm. of Pelletierine Tannate is soluble in about 250 cc. of water at 25° C. It is soluble in alcohol, slightly soluble in ether, and insoluble in chloroform. It is dissolved by warm dilute acids.

" Its saturated, aqueous solution is acid to litmus paper. A saturated aqueous solution of the salt is colored blue-black by ferric chloride T.S.

" The ash from 0.2 Gm. is negligible. Platinic chloride T.S. produces no precipitate in a cold solution of about 0.1 Gm. of Pelletierine Tannate in a mixture of 4 cc. of distilled water and 1 cc. of diluted hydrochloric acid (*many foreign alkaloids*). Dissolve about 0.5 Gm. of Pelletierine Tannate, accurately weighed, in 5 cc. of sodium hydroxide T.S., and shake the solution with four successive portions of 10, 5, 5, and 5 cc. of chloroform. Acidulate the combined chloroform solutions with 0.1 cc. of hydrochloric acid, evaporate to apparent dryness on a water bath, dissolve the residue in 5 cc. of alcohol, again evaporate, and dry for one hour at 60° C. The weight of the residue is not less than 20 per cent. of the weight taken. Stir about 0.001 Gm. of the residue obtained in the preceding test on a white, porcelain surface with 2 drops of sulphuric or nitric acid: no other than a light yellow or slightly brown color is produced.

" Preserve in small, well-closed containers, protected from light." *U. S.*

" A light yellow, amorphous powder. Slightly soluble in *water,* more soluble in *alcohol* (90 per cent.). An aqueous solution gives with *T. Sol. of ferric chloride* a bluish-black color; with *solution of silver nitrate* a brown color rapidly deepening, with separation of metallic silver; and with *solution of auric chloride* a deep purple color, with separation of metallic gold. When heated, Pelletierine Tannate turns brown at about 150° C., softens at about 165° C.; and at a higher temperature decomposes without melting. No appreciable ash." *Br.*

Uses.—For account of the physiological and therapeutic properties of this substance see under *Granatum.* It is chiefly used as a tænifuge.

Dose, three to five grains (0.2–0.3 Gm.).

PEPO. U. S. (Br.)

PEPO [Pumpkin Seed]

" Pepo is the dried ripe seed of cultivated varieties of *Cucurbita Pepo* Linné (Fam. *Cucurbitaceæ*). Pepo contains not more than 5 per cent. of broken or defective seed or other foreign organic matter." *U. S.* " Melon Pumpkin Seeds are the prepared fresh ripe seeds of cultivated plants of Cucurbita maxima, *Duch.* Melon Pumpkin Seeds must not be more than one month old, and when required for use about 100 grammes are bruised with a little water or milk to a creamy consistence and administered as a single dose." *Br.*

Cucurbitæ Semina Præparata, *Br.;* Melon Pumpkin Seeds; Semen Peponis, Semina Cucurbitæ; Semences de Potirons ou de Courge, *Fr.;* Kürbissamen, Kürbiskörner, Graumontsamen, *G.;* Calabaza (Semilla), *Sp.*

Cucurbita Pepo L. is an annual, long running, monœcious herb with prickly stems and petioles indigenous to tropical America, having been cultivated in fields of maize by the aborigines when the first settlers arrived on the American continent. It is further characterized by possessing 3- to 5-lobed, dark dull green leaves, large yellow axillary flowers and pepo fruits, the latter differing in size and shape in the numerous varieties and strains cultivated. Much confusion exists in the usage of the terms " pumpkin " and " squash," these terms having been applied almost indiscriminately to varieties of several species of *Cucurbita.* The various field or pie pumpkins and the summer squashes represent cultivated varieties of *C. Pepo.* The Hubbard, Turban, Marblehead and Sibley squashes are cultivated varieties of *C. maxima* Duchesne. The Canada Crookneck, Winter Crookneck and China squashes are cultivated varieties of *C. moschata.* The seeds of *C. Pepo* are recognized by the U. S. and of *C. maxima* by the Br.

Description and Physical Properties.—" *Unground Pepo.*—Broadly elliptical or ovate, from 15 to 23 mm. in length and from 2 to 3 mm. in thickness; externally yellowish-white, very smooth, occasionally with thin, transparent fragments of adhering pulp and with a shallow groove parallel to and within 1 mm. of the margin; fracture short; seed-coat consisting of a white coriaceous outer layer and a membranous inner layer occasionally of a dark green color; embryo whitish, straight, with a small conical hypocotyl and 2 plano-convex cotyledons; slightly odorous when contused; taste bland and oily.

" *Structure.*—An outer epidermal layer consisting of palisade-like cells, the radial walls attaining a length of 1 mm., the outer walls being usually torn off so that it appears as though the seeds were covered with very long hairs; a sub-epidermal layer consisting of from 5 to 12 rows of cells with slightly thickened, lignified and porous walls; a layer of strongly lignified stone cells, elliptical in outline and about 0.075 mm. in length; a single layer of small cells resembling those of the sub-epidermal layer; several rows of parenchyma cells with characteristic, reticulate markings and separated from each other by large intercellular spaces; several layers of parenchyma cells, the inner layer being more or less collapsed and bounded on the inside by a single epidermal layer, the cells having rather thick walls; the perisperm cells usually more or less collapsed and the endosperm consists of a single layer of cells filled with small, aleurone grains; the cotyledons consist of thin-walled, isodiametric, elongated or palisade-like cells containing a fixed oil and numerous small, aleurone grains." *U. S.*

The British Pharmacopœia recognizes the *melon pumpkin* seeds, under the title of *Cucurbitæ Semina Præparata.* These are derived from a closely related species, *Cucurbita maxima* Duch., which closely resembles *C. Pepo* and differs in that the margins of the leaves possess rounded teeth, whereas in *C. Pepo* they are acute. The British definition and description are as follows: "Flat, ovate, white, and exalbuminous, consisting of two fleshy, easily separable cotyledons, freshly deprived of the yellowish outer, and brownish inner integument. Faint odor; taste very slight. Before preparation, the seeds measure from eight to twenty millimetres in length, and from nine to twelve millimetres in breadth." *Br.*

Although Dorner and Wolkowich reported an alkaloid, *cucurbitine,* in pumpkin seed in 1862, subsequent chemists have not been able to confirm its presence. Power and Solway (*J. Am. C. S.*, 1910, xxxii, p. 346) obtained by expression about 19 per cent. of a reddish fixed oil. This had a specific gravity at 20° C. of 0.922, acid value 3.4, saponification value 189.4, iodine value 119.7; it was composed of 45 per cent. of the glyceride of linoleic acid, the remainder being olein, palmitin and stearin (see also Graham, *A. J. P.*, 1901, p. 352).

In 1875 Heckel obtained a resin which he believed was the active principle. Power and Solway tested both the resin and the oil from pumpkin seed but were unable to find evidence of any vermifuge effect. We must at present, therefore, consider that we have no knowledge of the real active principle of this remedy.

W. E. Miller (*A. J. P.*, 1891, 585) analyzed both the shells and the kernels of pumpkin seed. He also found a resin soluble in alcohol, and a dark reddish fixed oil.

Uses.—The seeds of various species of cucurbita have been used for more than a century in the treatment of *tapeworm.* The use of pumpkin seems to have been introduced into the United States by Soule (*B. M. S. J.*, 1851). Because of its harmlessness it became, and has continued, a favorite vermifuge for this purpose although from time to time its efficacy is denied. De Jongh (*P. J.*, 1917, xcviii, p. 307) reports satisfactory results in the case of infection by the *Tænia nana.* Sollmann (*J. P. Ex. T.*, 1918, xii, 129) has offered a plausible explanation of the varying esteem of this drug; he finds that the infusion of fresh pumpkin seed has a very markedly toxic action on earth worms but that a similar preparation from old seeds is much less efficient.

In treating tapeworm with this drug the patient should be allowed only a light supper of bread and milk, in the morning early should take an ounce and a half of the seeds, a cup of tea or coffee an hour later, but no food; at 10 A. M. a brisk cathartic, and two hours later a substantial meal. We have obtained excellent results from the exhibition of the beaten seeds in the form of an electuary strongly flavored with oil of cinnamon or of gaultheria.

Dose, one to two ounces (31–62 Gm.).

PEPSINUM. U. S., Br.

PEPSIN Pepsin.

"Pepsin is a substance containing a proteolytic enzyme obtained from the glandular layer of the fresh stomach of the hog, *Sus scrofa* var. *domesticus* Gray (Fam. *Suidæ*). Pepsin digests not less than 3000 times its own weight of freshly coagulated and disintegrated egg albumen. Pepsin of a higher digestive power may be brought to this standard by admixture with pepsin of a lower digestive strength or with lactose." *U. S.* "Pepsin is an enzyme obtained from the fresh and healthy stomach of the pig, sheep, or calf." *Br.*

Pepsine, *Fr. Cod.;* Pepsinum, *P. G.;* Pepsin, *G.;* Pepsina, *It.;* Pepsina medicinal, *Sp.*

There is secreted by certain glands in the stomach an enzyme which, in the presence of a slightly acid medium, is capable of converting proteins into proteoses and peptones. This ferment, which is known to the physiologists under the name of pepsin, has never been isolated in a pure condition; the substance known in the Pharmacopœias by the name of "pepsin" contains, besides the ferment itself, varying quantities of inert protein matter. Pepsins having much greater digestive capacity than that chosen for the U. S. official standard have been manufactured, but for all practical purposes the official pepsin is sufficiently concentrated, and indeed it is usually diluted for internal administration.

The British Pharmacopœia of 1885 gave a method for the manufacture of pepsin which consisted simply in scraping the cleansed mucous membrane of the stomach and drying the resulting pulp on glass plates. This process can not give the full enzyme content of the mucous membrane as the peptic ferment does not exist as such in the cells of the mucous membrane, but only as a compound known as *propepsin* or *pepsinogen* which, in the presence of hydrochloric acid is converted into active pepsin. The modern methods of manufacturing pepsin may be briefly stated as follows. The inner membranous linings of hogs' stomachs are washed, passed through a mincing machine, and the resulting mass digested with diluted hydrochloric acid; the solution is strained or filtered and evaporated *in vacuo* or placed on shallow trays, so that a syrupy liquid, which has not been subjected to a higher temperature than 44.5° C., is produced; this is spread upon glass plates to dry, and the scales which are formed scraped off. The thickness of the scales may be varied by using more or less concentrated solutions, and the proportion of peptone is increased by extending the length of time in the digestion process and raising the temperature to the utmost safe limit. Pepsin appears to belong to the group of true albumins; that is—those proteins which are soluble in water but may be precipitated from their aqueous solution by various neutral salts. Practical application of this fact has been made in concentrating pepsin.

Three distinct types of pepsin are found in commerce: (1) Pepsins insoluble in water without the addition of traces of acids; (2) Pepsins soluble in water forming transparent solutions: (3) Pepsins not entirely soluble in water or in diluted hydrochloric acid. The objection to the insoluble pepsins is, of course, the inconvenience resulting from their insolubility in water, but, on the other hand, they are not hygroscopic, do not deteriorate so rapidly, and are active in contact with the gastric juice. The objection to the soluble pepsins is that they are hygroscopic, but they are, when good, well suited for making solutions, wines, etc. Most of the pepsin used at the present time is what is known as scale pepsin and contains from 8 to 12 per cent. of hydrochloric acid.

Description and Physical Properties.—"Lustrous, white or pale yellow, transparent or translucent scales, granules or spongy masses, or a fine, white or cream-colored, amorphous powder, free from any offensive odor, and having a slightly acid or saline taste. It is not more than slightly hygroscopic. Pepsin is freely soluble in water, the solution being more or less opalescent. It is nearly insoluble in alcohol, chloroform, and ether. Dry Pepsin is not injured by heating to 100° C. The activity of Pepsin in solution is destroyed by alkalies or by temperatures exceeding 70° C.

"An aqueous solution of Pepsin (1 in 50) is acid to litmus paper. An aqueous solution of Pepsin yields precipitates with solutions of tannic or gallic acid and with solutions of the salts of many heavy metals. On heating a saturated solution of Pepsin in acidulated water to 100° C., it becomes milky or yields a light, flocculent precipitate, and loses all proteolytic power.

"Preserve in well-closed containers." *U. S.*

Assay.—"Mix 25 cc. of normal hydrochloric acid with 275 cc. of distilled water. Dissolve 0.1 Gm. of Pepsin in 150 cc. of this acid. Select a hen's egg, which is not less than five and not more than twelve days old and has been kept in a cool place, and immerse it in boiling water during fifteen minutes. As soon as the egg has sufficiently cooled to handle, remove the shell and pellicle and all of the yolk and at once rub the albumen through a clean, dry, hair or brass, No. 40 sieve, reject the first portion that passes through the sieve, and place 10 Gm. of the succeeding portion in a wide-mouthed bottle of 100 cc. capacity. Immediately add 20 cc. of the acid and stir the mixture well with a rubber-tipped glass rod so as to separate thoroughly the particles of albumen from each other. Rinse the rod with 15 cc. more of the acid and, after warming the mixture to 52° C., add exactly 5 cc. of the acidulated solution of Pepsin. At once cork the bottle securely, invert it three times, and place it in a bath that has been previously regulated to maintain a temperature of 52° C. Keep the bottle at this temperature for two and one-half hours, agitating the contents every ten minutes by inverting at once. Then remove it from the bath, pour the contents into a conical measure having a diameter not exceeding 1 cm. at the bottom, and transfer the undigested egg albumen, which adheres to the sides of the bottle, to the measure with the aid of small portions (about 15 cc. at a time) of distilled water, until the total amount used measures 50 cc. Stir the mixture well and allow it to stand for half an hour. The deposit of undissolved albumen does not measure more than 1 cc.

"The relative proteolytic power of pepsin, stronger or weaker than that just described, may be determined by ascertaining through repeated trials the quantity of the Pepsin solution made as directed in the assay, required to digest, under the prescribed conditions, 10 Gm. of boiled and disintegrated egg albumen. Divide 15,000 by this quantity expressed in cc. to ascertain how many parts of egg albumen one part of Pepsin will digest." *U. S.*

"A light yellowish-brown powder, or pale yellowish, translucent scales, having a faint odor. Tested as follows it dissolves 2500 times its weight of coagulated white of egg in six hours, the resulting solution being faintly opalescent:—Prepare some coagulated white of egg by boiling fresh eggs in water for fifteen minutes, immersing them in cold water until cool, separating the whites, at once rubbing these through a hair-sieve having 12 meshes to a centimetre, and using the product before it has lost moisture by evaporation. Prepare also a Pepsin solution by triturating 0.25 gramme of the Pepsin with 1 gramme of *sodium chloride* in a small mortar until thoroughly mixed, adding by degrees acidified water (prepared by diluting 6.5 millilitres of *hydrochloric acid* to 1000 millilitres with *water*), continuing the trituration, transferring to a litre flask, washing the mortar with acidified water, and adding the washings to the contents of the flask until 1000 millilitres are produced, then shaking frequently during six hours, and again immediately before use. Introduce 20 millilitres of the Pepsin solution so prepared into a 250 millilitre flask. Triturate 12.5 grammes of the freshly prepared coagulated white of egg in a small mortar with 50 millilitres of acidified water until reduced to uniform granules. Transfer to the flask, rinsing the mortar with a further 50 millilitres of acidified water, adding the rinsing to the contents of the flask. Immerse the flask in a water-bath so that its contents are on a lower level than the water in the bath, and digest at a temperature between 40° and 41° C. for six hours, shaking at intervals of fifteen minutes." *Br.*

The conditions that effect the rapidity of peptic digestion are so many that it is necessary to adhere with great strictness to each detail of the assay method. One of the variables which has caused considerable difficulty is the albumin. The present Pharmacopœia attempts to meet this trouble by a strict definition of the conditions for preparation of the egg. A number of authorities have advocated the use of *edestine,* a globulin found in the cereal grains (see *Bull. Sci. Pharm.,* 1915, xxii, p. 24 and *P. J.,* 1915, xciv, p. 389). Chestnut has advocated the use of ricin, the protein of castor beans, and has devised a method which he believes is more accurate than that of the U. S. P. and which involves the comparison with a standard pepsin (see Fuller, *Chemistry and Analysis of Drugs,* 1920, page 898).

Incompatibilities.—The peptic ferment is an extremely unstable body being destroyed by tannins, alcohol, the salts of the heavy metals and strong acids. Tocher, as the result of an experimental study, concludes that: Solutions of sodium bicarbonate, sodium, potassium, and ammonium hydrates when added to solutions of pepsin in the cold have an immediate inhibitory or destructive effect on pepsin, according to the concentration; dilute solutions of caustic alkali immediately destroy the activity of dilute solutions of pepsin; subcarbonate of bismuth precipitates pepsin from aqueous solutions: subnitrate does not; compound mixtures containing solution of bismuth, morphine, carmine, etc., should contain no pepsin, since the activity of the enzyme is much retarded by the morphine and is destroyed proportionately to the amount of alkali present in solution. (*Year Book of Pharmacy,* 1906, pp. 307–313.) The chemical relations of pepsin are so delicate and widespread that it ought to be given by itself, or in combination only with an insoluble substance, or suspended in inert liquids.

Uses.—Gastric juice was used by Dr. P. S. Physick, the celebrated physician of Philadelphia, nearly a century ago as a local application in *cancers* and *sloughing ulcers,* with a view of removing the dead flesh and correcting the offensive odor and affording a healthy stimulus to the diseased surface. The first to have suggested pepsin as a remedy in disturbances of the stomach seems to have been Corvisart. (*J. P. C.,* xxx, p. 169.) It is now very largely used with the idea of improving the digestive powers of the stomach by supplying the essential ferment. Its value in *dyspepsia,* however, is greatly over-estimated. *Pepsinogen*—from which the active peptic enzyme is derived by the action of the hydrochloric acid—is rarely lacking save in cases of cancer and other very severe diseases of the stomach. When gastric digestion fails it is generally because of the absence of hydrochloric acid in sufficient quantity to activate the pepsinogen. Therefore, in our opinion pepsin is not indicated in the ordinary types of *indigestion* or *gastritis.* It appears, however, to have some sedative influence upon the mucous membrane of the stomach, not due to its digestive powers, and is often of service for the relief of certain forms of *nausea* and to lessen the ill effects of such drugs as the iodides and salicylates upon the stomach. Locally it is still used occasionally for the purpose of dissolving the false membrane in *diphtheria* and hastening the sloughing off of dead tissue in *foul ulcers.*

It would seem trite to say that when pepsin is used as a digestive ferment it must be given in an active form and in sufficient dose to have some influence, were it not for the fact that this truism is so often forgotten. The enzymic activity of pepsin is so easily destroyed by heat and chemical agents, that it should be administered always either alone as a powder or in solution with minute quantities of hydrochloric acid only. The dose of four or five grains of pepsin so often recommended is quite inadequate to seriously influence gastric digestion; if the physician is employing the pepsin with any idea of hastening digestion he should give at least from fifteen to thirty grains (1–2 Gm.) at a dose.

Pepsin should preferably be administered in its original form. It is well to combine it with hydrochloric acid, and the powder is often advantageously exhibited in *infantile diarrhea* along with bismuth subnitrate. With these exceptions, it is usually preferable to give it by itself.

Dose, of official pepsin, may be set down as from ten to sixty grains (0.65–3.9 Gm.).

PERSIO. N. F.

CUDBEAR

"Cudbear is a purplish red powder prepared from species of *Rocella* De Candolle, *Lecanora Acharius,* or other lichens. Cudbear yields not more than 12 per cent. of total ash." *N. F.*

Orseille de Terre, *Fr.;* Rothe Indigo, Persio, *G.*

Three purple or blue coloring substances obtained from various lichenous plants are known in commerce under the names of litmus (see Part II), orchil and cudbear. The species of lichens concerned represent various genera; at present the two most important of the lichens are said to be the *Roccella Montagnei* Bel. of Mozambique and the *Dendrographa leucophœa* Darbish of California. In the north of Europe *Lecanora tartarea* Ach., or *Tartarean moss*, and on the Mediterranean coasts the *Roccella tinctoria* Ach., or *orchilla weed*, at one time furnished the great bulk of the orseille of commerce. The chromogenous ethers which constitute the coloring matter of the lichens may be readily detected *in situ* by reagents. (*P. J.*, Nov. 19, 1904.) In some of the lichens these coloring principles are chiefly situated in the cortex; in others they are especially abundant in the gonidial layer.

These lichens are brought into commerce from the coasts of Sweden and Norway; from the Alps, the Pyrenees, and other European mountains; from the European and African coasts of the Mediterranean; from the Canaries, Madeira, and various other rocky islands, especially from Mozambique, Madagascar, and Angola, and from California.

Cudbear is prepared by macerating the lichens with diluted ammonia, probably also with the addition of potassium or sodium hydroxide, for several days. After the proper fermentation has occurred the mixture is dried and powdered.

Orchil (*archil, orseille*) seems to differ in its preparation from cudbear in that, after fermentation, sulphuric acid and sodium chloride are added. It is used as a dye-stuff, especially for modifying the tinctorial effect of other dyes as indigo.

Physical Properties and Tests.—"An aqueous or alcoholic preparation of Cudbear is of a deep red color which is rendered lighter in tint by the addition of acids, and is changed to purplish red on the addition of alkalies. Agitate 2 Gm. of Cudbear occasionally with 200 cc. of water during thirty minutes and then filter; the deep red-colored filtrate conforms to the following tests: Add to 5 cc. of the filtrate 5 drops of glacial acetic acid and boil for one minute; then add 5 drops of stannous chloride T.S., and boil again for one minute; the liquid is only faintly pink (*brazilwood or logwood* which produce solutions of a deep red color); add 25 Gm. of kaolin to 100 cc. of the filtrate in an Erlenmeyer flask, shake frequently during one hour and then filter; the filtrate is almost entirely decolorized in comparison with some of the original filtrate (a number of coal tar colors)." *N. F.*

Constituents.—The principles in these plants upon which their valuable properties depend are themselves colorless, and yield coloring substances by the reaction of water, air, and ammonia. They are generally acids or acid anhydrides, and are named *lecanoric, orsellic, erythric,* etc., according to their origin. *Lecanoric* (*diorsellinic*) *acid*, $C_{16}H_{14}O_7$, the original constituent of most of these plants, when boiled with water or alkaline solutions, is changed into *orsellinic acid*, as follows:

$$C_{16}H_{14}O_7 + H_2O = (C_8H_8O_4)_2$$

Orsellinic acid,  $C_6H_2\begin{cases}CH_3\\(OH)_2\\COOH\end{cases}$, fuses at 176° C., and decomposes into *orcin*, $C_6H_3(CH_3)(OH)_2$, and CO_2. The same decomposition is readily effected by distillation with milk of lime. Orcin combines with ammonia gas to form $C_8H_8O_2.NH_3$, the solution of which exposed to the air becomes colored reddish by the formation of *orcëin*, $C_7H_7NO_3$. This latter compound forms the basis of *orchil*.

Kane described a deep red crystalline substance, *erythrolitmin*, and a brownish-red coloring principle, *azolitmin*, $C_7H_7NO_4$. This latter is considered as the distinctive coloring matter of the commercial litmus, and is now found in commerce under that name and is used as an indicator. It is nearly insoluble in cold water or benzene, but dissolves in alcohol with red, and in ether with yellow color. It appears to have the characters of a weak acid, the salts of which are blue and the potassium and calcium compounds of which exist in litmus.

To test the value of the plants as dye-stuffs, they may be macerated in a weak solution of ammonia, or a solution of calcium hypochlorite may be added to their alcoholic tincture. In the former case a rich violet-red color is produced; in the latter, a deep blood-red color appears, but soon fades.

George M. Beringer has given much attention to cudbear with a view of securing a uniform product. (See *Proc. New Jersey Pharm. Assoc.*, 1912, 56.) He declares that all of the ordinary methods, as color charts, colored yarns, threads, glass, etc., are unsatisfactory and inapplicable to pharmacy. He advocates the preliminary purification of cudbear by washing it with water to remove the sodium chloride so largely used as a diluent and the ammonium salts with their empyreumatic odor and states that if the washing is properly done the cudbear loses scarcely any of its tinctorial power. He believes that the best results would follow the preparation and use of a standard extract. Alexander Gardner gives the name *persionin* to an acetone extract of cudbear made as follows: Percolate commercial cudbear with purified benzin until free from wax, then dry and percolate with acetone to exhaustion—about 2500 cc. being required for 1000 Gm. of cudbear. The acetone is recovered by distillation, the residual extract heated for thirty minutes to 98.8° C. in a porcelain capsule, then pulverized and placed in a sulphuric acid desiccator for three days, during which it loses about 25 per cent. of its weight. So obtained, "persionin" is a black, lustrous powder with an aromatic odor, soluble in alcohol, glycerin, chloroform, ether, and hydroalcoholic liquids, but is only sparingly soluble in water. Five different lots of cudbear yielded, from 5 to 7 per cent. of persionin. Each sample of "persionin" was tested by dissolving 1 part in 100 parts of alcohol and 3 parts of glycerin. One cc. of this was added to 99 cc. of distilled water, and in each particular the color was the same. (*J. A. Ph. A.*, 1913, 51–52.) H. V. Arny (*J. A. Ph. A.*, 1913, 47) proposes to remove a brown pigment present in cudbear (which interferes with the tinctorial power) by macerating an alcoholic extract with chloroform and extracting the residue with acetone. The final product is then "scaled."

Because of the difficulty of completely extracting cudbear the liquid preparations are rarely uniform in color value. For this reason the N. F. uses powdered cudbear in several preparations, allowing it to macerate until all color is extracted. This plan results in more uniform coloring than if the tincture was directed.

Cudbear is used solely for its tinctorial properties.

PETROLATUM. U. S. (Br.)

PETROLATUM Petrolat. [Amber Petrolatum, Yellow Petroleum, Petroleum Jelly]

"A purified, semi-solid mixture of hydrocarbons, obtained from petroleum." *U. S.* "Soft Paraffin is a mixture of semi-solid hydrocarbons." *Br.*

Paraffinum Molle, Soft Paraffin, *Br.;* Adeps Petrolei, Unguentum Paraffinum; Petrolinum; Unguentum Petroleis; Soft Petrolatum, Cosmoline, Vaseline, Paraffin Jelly, Petroleum Jelly, Petroleum Ointment; Vaselinum, *P. G.;* Graisse minérale, Pétréoline, *Fr.;* Weiches Paraffin, Paraffinsalbe, *G.;* Vaselina, *It., Sp.*

Petrolatum is prepared from the residue left in the stills after a distillation of petroleum *in vacuo,* or from the residue or sediment deposited in tanks containing crude petroleum, of which large quantities collect in the storage tanks in the oil districts of western Pennsylvania. It is made on a large scale from residues, but more largely from what are termed "reduced oils," that is, crude oils from which the lighter fractions (those included under the heads of petroleum benzin, naphtha, illuminating and paraffin oils) have been removed by distillation. This process of reducing would leave an increasing amount of black pyrogenous products in the residue, were it not that the reducing is carried out under diminished pressure, by what is termed the "vacuum process," in which, moreover, the heat is not applied directly to the still bottoms, but by means of coils of pipe, through which superheated steam is made to pass. These reduced oils can be brought to 337.7° C. fire-test without acquiring the slightest pyrogenous odor. They are then filtered through well-dried bone black, in chambers kept at a temperature of from 43.3° to 54.4° C., or in some cases higher. The first portions of the filtrate are colorless, and then pass from a light straw or amber color to a red color by transmitted light and light green by reflected light. The latter product is known as "cylinder stock," and is highly prized as a lubricating oil. The crude oil tank residues are purified in a similar manner. The "B. S. Oil," or "rod wax," as it is technically termed, is placed in a still, heat applied, and after the lighter products have distilled over, and indications of congelation are noticed when a portion of the distillate is allowed to cool, the heat is withdrawn, and the contents of the still, after having cooled, are transferred gradually to a percolator which contains recently heated animal charcoal. In place of bone black, clay has in recent years been quite largely used for clarifying purposes, the same being revivified by heat. A somewhat different process is used in Germany; the crude product is derived from crude *ozokerite,* obtained from Alsace and Galicia, or American residue is sometimes used. (1) The oil is heated by steam to about 30° C., mixed, at this temperature, with 10 per cent. of its weight of sulphuric acid of 60° B., stirred for half an hour, and then allowed to stand at rest, so that the carbonized portions may separate. (2) When clear, the oil is washed with an aqueous solution of potassium dichromate, whereby any remaining excess of sulphuric acid is at the same time removed. (3) The residue from the acid treatment is mixed with lime, neutralized, and disposed of to fertilizer factories. (4) The clear oil from the second step of the process, after being washed, is heated by steam to 80° C., mixed with 10 per cent. of its weight of granular animal charcoal, and then allowed to stand at rest, to permit the animal charcoal to settle. (5) After the latter is separated, the liquid portion is filtered through filters heated by steam. (6) The residuary magma of animal charcoal is subjected to hydraulic pressure, the expressed oil filtered, and the solid residue again used in the next operation, a sufficient quantity of fresh animal charcoal being added to make up for any loss or waste.

The commercial varieties of petrolatum may be classed under two heads: (1) Those which, like the American vaseline, are obtained as a ready formed mixture of hydrocarbons of gelatinous consistence; (2) those made by directly mixing solid paraffin of low melting point with heavy lubricating oil, such as are known in Germany as "artificial vaseline." The latter varieties are less homogeneous, and are liable to deposit granules of paraffin on keeping, and hence are not so suited for the preparation of ointments as true American petrolatum.

In warm ether, American petrolatum dissolves freely to a clear solution exhibiting a strong blue fluorescence, and the liquid remains clear, or at most becomes only slightly turbid, on cooling. German petrolatum, on the contrary, is said to form a thick solution with warm ether, and to give a considerable deposit on cooling. Russian petrolatum is stated to dissolve completely in warm ether and give a clear solution which becomes turbid on cooling. (Allen, *Com. Org. Anal.*, 2d. ed., 1887, ii, p.

408.) In the U. S. P. there are three forms of petrolatum as follows: Petrolatum, Petrolatum Album, and Petrolatum Liquidum. In the British Pharmacopœia there are three as follows: Paraffinum Liquidum, Paraffinum Molle, and Unguentum Paraffini. The Petrolatum of the U. S. P. X corresponds with the *Petrolatum Spissum* of the U. S. Pharm., 1890. The Paraffinum Molle of the British Pharmacopœia resembles the *Petrolatum Molle* of the U. S. P. 1890, but is somewhat softer in consistence.

Chemical Constitution.—Petrolatum, as made from American petroleum, consists mainly of the higher members of the paraffin series, but undoubtedly contains also the higher olefines. Puckner (*A. J. P.*, July, 1914) states that American petrolatum is made up of hydrocarbons of the methane series while the Russian oil contains naphthenes. These may possibly alter in time, and give rise to rancidity, although this is not certainly established. The paraffins, which make up the bulk of it, are not capable of direct oxidation, and are therefore not affected by atmospheric influences. Petrolatum contains hydrocarbons of the paraffin series, like $C_{16}H_{34}$, $C_{17}H_{36}$, $C_{18}H_{38}$, etc., up probably to $C_{32}H_{66}$, together with hydrocarbons of the olefine series, $C_{16}H_{32}$, $C_{17}H_{34}$, etc. These latter are less concrete than the corresponding paraffin hydrocarbons, and give petrolatum its oleaginous characters.

Description and Physical Properties.—" An unctuous mass, varying in color from yellowish to light amber. It has not more than a slight fluorescence even after being melted, and is transparent in thin layers. It is free or nearly free from odor and taste. Petrolatum is insoluble in water; almost insoluble in cold or hot alcohol, and in cold dehydrated alcohol. It is freely soluble in benzene, carbon disulphide, chloroform, and oil of turpentine. It is soluble in ether, petroleum benzin, and in most fixed or volatile oils, the degree of solubility in these solvents varying with the composition of the Petrolatum.

" Specific gravity: 0.820 to 0.865 at 60° C. It melts between 38° and 54° C. Heat 2 Gm. of Petrolatum in an open porcelain or platinum dish over a Bunsen flame: it volatilizes without emitting an acrid odor, and on incineration leaves not more than 0.05 per cent. of ash. Shake melted Petrolatum with an equal volume of hot distilled water: the latter remains neutral to litmus paper (*acids or alkalies*). Digest 10 Gm. of Petrolatum, at 100° C., with 10 Gm. of sodium hydroxide and 50 cc. of distilled water for half an hour, then separate the aqueous layer, and supersaturate it with sulphuric acid: no oily or solid substance separates (*fixed oils, fats, or rosin*)." *U. S.*

" White or yellow, translucent, soft, unctuous to the touch, not allowing any liquid to separate on keeping. No odor. Melting point 42° to 46° C. On heating to 80° C. no unpleasant odor is evolved. 10 millilitres of *alcohol* (90 per cent.) boiled with 5 grammes of Soft Paraffin are not acid to *litmus.* When 10 grammes are boiled with 20 millilitres of *solution of sodium hydroxide* for ten minutes and allowed to separate, the aqueous layer yields no precipitate or oily matter when acidified with *sulphuric acid* (absence of fixed oils, fats, and resin). 5 grammes when heated burn with a luminous flame, leaving no appreciable ash." *Br.*

As it is found in the market, petrolatum varies in color, odor, and melting point. The statement frequently made by the manufacturers that it is unalterable in the air is incorrect, as we have frequently noticed that exposure to light and air causes it to assume a disagreeable odor resembling that of crude petroleum. It has been observed to have at times irritating properties. These may be due to imperfect removal of the sulphuric acid or similar agents used, but are more probably caused by rancidity or decomposition.

Uses.—Petrolatum is used almost exclusively as a bland, neutral, protective dressing and as a substitute for the true fats in ointments. For local applications it has the advantage over the fats that it does not so readily become rancid. It is not suited, however, for the preparation of ointments when absorption is desired, for it does not readily penetrate the skin. Although it was at one time suggested as a substitute for butter and animal fats for culinary purposes it has absolutely no food value. Randolph (*T. G.*, 1885, ix, p. 732) appears to have been the first to demonstrate its non-absorbability from the intestinal tract, and Robinson (*M. News*, 1900, lxxvii, p. 56) recovered the entire amount of liquid petrolatum from the feces which was administered by mouth. Randolph also showed that when taken internally, in doses of from one to four drachms (3.9–15.5 Gm.), it acts as a feeble laxative and soothes irritation, so as to be advantageous in inflammations of the gastro-intestinal mucous membrane. (See *Petrolatum Liquidum.*)

Off. Prep.—Unguentum Paraffini, *Br.;* Emulsum Petrolati, *N. F.;* also used as base for several ointments.

PETROLATUM ALBUM. U. S.

WHITE PETROLATUM Petrolat. Alb. [White Petroleum Jelly]

" Petrolatum wholly or nearly decolorized." *U. S.*

In the manufacture of petrolatum, as described in the previous article, the final step is partial decolorization by means of animal charcoal; by carrying this decolorization somewhat further the product may be obtained almost water white. This is the substance which is officially known as *Petrolatum Album.*

An imitation of this ointment base, made by melting together paraffin and white liquid petrolatum has appeared on the market under various descriptive names, such as *snow white mineral jelly,* etc., is extensively used in preparing petrolatum cold creams, but usually separates some of the liquid portion when the attempt is made to incorporate other ingredients by rubbing. This manufactured product is opalescent and usually granular in appearance and is excluded by the official description.

Description and Physical Properties.—"White Petrolatum is a white or faintly yellowish unctuous mass, transparent in thin layers even after cooling to 0° C.

"In other respects White Petrolatum has the characteristics of and responds to the tests for identity and purity under *Petrolatum.*" *U. S.*

Uses.—See *Petrolatum.*

PETROLATUM LIQUIDUM. U. S. (Br.)

LIQUID PETROLATUM Petrolat. Liq. [Liquid Paraffin, White Mineral Oil, Paraffin Oil]

"Liquid Petrolatum is a mixture of liquid hydrocarbons obtained from petroleum." *U. S.* "Liquid Paraffin is a mixture of liquid hydrocarbons." *Br.*

Paraffinum Liquidum, *Br.;* Liquid Paraffin; Vaselinum Liquidum; Oleum Paraffinæ; Paraffine liquide, Huile de Paraffine, *Fr.;* Flüssiges Paraffin, Paraffinöl, *G.;* Aceite de parafina, *Sp.*

Preparation.—*Liquid petrolatum* is made by distilling the residuary liquid boiling between 330° and 390° C., obtained after removing the lighter hydrocarbons from petroleum. It is purified and decolorized by first treating it with sulphuric acid and then with caustic soda and passing it while hot, through animal charcoal. By cooling, some solid paraffins will separate; the liquid is then redistilled, and the portion boiling below 360° C., rejected.

Description and Physical Properties.—"*Heavy Liquid Petrolatum.*—Heavy Liquid Petrolatum has a kinematic viscosity of not less than 0.381 at 37.8° C.

"*Light Liquid Petrolatum.*—Light Liquid Petrolatum has a kinematic viscosity of not more than 0.370 at 37.8° C. Each variety conforms to the following description and tests:

"A colorless, transparent, oily liquid, free, or nearly free, from fluorescence. It is insoluble in water and in alcohol; soluble in ether, chloroform, petroleum benzin, and in fixed or volatile oils. Camphor, menthol, thymol, and many similar substances are soluble in Liquid Petrolatum.

"Specific gravity: 0.828 to 0.905 at 25° C.

"Liquid Petrolatum is odorless and tasteless when cold, and develops not more than a faint petroleum odor when heated. When cooled to 0° C., Liquid Petrolatum does not become more than opalescent (*solid paraffins*). Boil 10 cc. of Liquid Petrolatum with an equal volume of alcohol: the alcohol remains neutral to moistened litmus paper (*acid or alkali*). Pour 5 cc. of Liquid Petrolatum and 5 cc. of colorless sulphuric acid into a glass-stoppered cylinder, which has been previously rinsed with sulphuric acid, and heat in a water-bath for ten minutes, shaking the mixture well at intervals of thirty seconds: the oil remains unchanged in color and the acid does not become darker than pale amber (*carbonizable substances*). Prepare a saturated solution of lead monoxide in an aqueous solution of sodium hydroxide (1 in 5), and mix 2 drops of the clear solution with 4 cc. of Liquid Petrolatum and 2 cc. of dehydrated alcohol: the mixture does not darken after heating at 70° C. for ten minutes and cooling (*sulphur compounds*).

"Preserve in well-closed containers, protected from light." *U. S.*

In the U. S. P. IX two kinds of Liquid Petrolatum were introduced, one being called "heavy," the other "light." The degree of viscosity is the determining factor. For atomizing purposes light liquid petrolatum is used and as a laxative heavy liquid petrolatum is preferred.

The British Pharmacopœia describes it as "transparent, colorless, not fluorescent. No odor or taste. Specific gravity 0.860 to 0.890. A mixture of 4 millilitres of Liquid Paraffin, 2 millilitres of *absolute alcohol,* and 2 drops of a clear saturated solution of *lead oxide* in *solution of sodium hydroxide,* remains colorless when kept at 70° C. for ten minutes (absence of sulphur compounds). When 3 millilitres are heated with an equal volume of *sulphuric acid* in a test-tube placed in boiling *water* for ten minutes, and frequently shaken, the acid layer, after separation, is not darker than pale-brown. 10 millilitres of *alcohol* (90 per cent.) boiled with 5 millilitres of Liquid Paraffin are not acid to *litmus.*" *Br.*

Uses.—Liquid petrolatum is used chiefly for one of two purposes. The first of these is as a demulcent upon the mucous membrane of the upper respiratory tract in acute *coryza, pharyngitis,* and *laryngitis.* It is usually applied by atomization but is sometimes dropped directly into the nostril. It has also been recommended as a dressing for *wounds* and *ulcers.* Chrysopathes (*Cb. Chir.,* 1913, p. 1739) believes that it has an antiseptic effect, but it is more probable that its beneficial action is due to the exclusion of air.

Although vaseline was recommended many years ago by Randolph for its laxative effect, it was not used to any large extent until in 1913 Lane (*B. M. J.,* 1913, ii, p. 1126) introduced the use of the heavy Russian liquid petrolatum in the treatment of *chronic constipation.* Since this time it has become a favorite remedy for this purpose. Its action is purely mechanical rendering the feces soft and perhaps lubricating the bowel. There is a wide-spread belief among the medical profession that where used as a laxative the more viscid petrolatums are preferable. In a comparative study, however, of both the Russian and American oils ranging in specific gravity from 0.857 to 0.885, carried out by eight of the most prominent clinicians in the United States under the auspices of the Council on Pharmacy and Chemistry of the American Medical Association (*J. A. M. A.*, 1915, lxiv, p. 808), the conclusion was reached that as far as the therapeutic results, either as regards the quantity required or the liability to leakage around the anus or other disagreeable effects, there is no difference in the effects of the heavy or light oils. The ordinary quantity required varied from one-half to three ounces, and the effects were the same whether taken in one or three doses. The use of liquid petrolatum hypodermically is a dangerous procedure. Mook and Wander (*J. A. M. A.*, 1919, lxxiii, 1340) report a series of inflamed tumors following the subcutaneous injection of a solution of camphor in liquid petrolatum and point out that fatal emboli have followed the injection of suspensions of mercury in petrolatum.

A formula for an emulsion of liquid petrolatum was contributed by Miles Shimer (*Proc. P. Ph. A.*, 1916, p. 298), as follows: Soft petrolatum, 40 Gm.; white mineral oil, 200 Gm.; powdered acacia, 60 Gm.; syrup, 50 cc.; rum (Jamaica), 50 cc.; water, q. s. ad., 500 cc.

The number of fancy names which have been applied to proprietary brands of liquid petrolatum has become a crying evil. The following are some of the common names and special brands of liquid petrolatum: Adepsine oil, American oil, amilee, atoleine, atolin, bakurol, blandine, crysmalin, deeline, glyco, glycoline, glymol, heavy petroleum oil, interol, lilyolene, liquid abolene, liquid cosmoline, liquid fossiline, liquid geoline, liquid paraffin, liquid petrolatum, liquid saxoline, liquid vaseline, mineral glycerin, mineral oil, minol, muthol, neutralol, nujol, olo, paraffin oil, paroline, petralol, petro, petrolax, petrolia, petronol, petrosio, rock oil, Russian liquid petrolatum, Russian mineral oil, Russian paraffin oil, russol, seneprolin, saxol, stanolax, stanolind, terraline, terralbolia, usoline, water-white mineral oil, white liquid vaseline, white paraffin oil, whiteruss.

Dose, three to six fluidrachms (11–22 cc.).

Off. Prep.—Nebula Aromatica, *N. F.;* Nebula Eucalyptolis, *N. F.;* Nebula Mentholis, *N. F.;* Nebula Mentholis Composita, *N. F.;* Nebula Thymolis, *N. F.*

PHENOBARBITALUM. U. S.

PHENOBARBITAL Phenobarb. [Phenylethylmalonylurea]

"Phenylethyl barbituric acid [$CO(NH.CO)_2C(C_2H_5)(C_6H_5)$]." *U. S.*

This drug differs in its chemical composition from barbital in that one of the ethyl groups has been replaced by a phenyl group. It was originally introduced under the trade name of *luminal*. The sodium salt, *luminal sodium*, is also upon the market and differs in being freely soluble in water.

Phenylethyl barbituric acid is prepared by condensing phenylethyl malonic acid derivatives and urea, or urea compounds, from cyanoacetic acid. The derivatives of the parent acid may be esters, amides, chlorides, nitriles, etc. The condensation may be carried out with urea or its thio, or alkyl derivatives, or with guanidine derivatives.

Description and Physical Properties.—"White, glistening, small crystals, or a white, crystalline powder. It is odorless, and is stable in the air. One Gm. of Phenobarbital is soluble in about 1000 cc. of water, 8 cc. of alcohol, 40 cc. of chloroform, 13 cc. of ether, and in about 700 cc. of benzene, at 25° C. It is soluble in solutions of alkali hydroxides and of alkali carbonates.

"Phenobarbital melts between 172° and 174° C. A saturated aqueous solution of Phenobarbital is acid to litmus paper. Boil about 0.2 Gm. of Phenobarbital with 5 cc. of a 25 per cent. sodium hydroxide solution: ammonia is evolved. Shake about 0.3 Gm. of Phenobarbital for two minutes with 1 cc. of normal sodium hydroxide and 5 cc. of distilled water, filter, and divide the filtrate into 2 portions. To 1 portion add mercuric chloride T.S.: a white precipitate is produced. To the other portion add silver nitrate T.S. a few drops at a time: a white precipitate is produced which at first redissolves but becomes insoluble when an excess of silver nitrate has been added.

"The ash from 0.5 Gm. is negligible. A solution of 0.2 Gm. of Phenobarbital in 2 cc. of sulphuric acid is colorless or only faintly yellow (*readily carbonizable substances*). Boil 2 Gm. of Phenobarbital with 10 cc. of alcohol under a reflux condenser during three minutes: a clear and complete solution results (*phenylbarbituric acid*)." *U. S.*

Uses.—Phenobarbital was originally introduced as a hypnotic for nervous *insomnia* and as a general nerve sedative, but has become of importance chiefly through its use in the treatment of *epilepsy*. Its effects in this disease appear to be, like those of the bromides, merely repressant and not truly curative. While it is undoubtedly of value in reducing the number of convulsions, especially where for any reason the bromides are unsuited, there is no evidence of any permanent curative effect.

According to Gruber and Baskett, large doses of phenobarbital have a marked depressant action on the circulation; they have observed falls of blood pressure of from 10 to 80 per cent.

Although when properly employed phenobarbital is a reasonably safe remedy, there have been a considerable number of cases of more or less serious toxic action, at least one of which ended fatally; Phillips (*J. A. M. A.*, 1922, lxxviii, p. 1199) has collected references to sixteen cases of poisoning. In his own patient, eight doses of 1½ grains taken daily for eight days, produced a violent morbilliform eruption accompanied with high fever and some irritation of the kidneys. Although amaurosis, mental confusion, ataxia and aphasia have been reported in isolated cases, in the majority of instances the symptoms have been of the type just described. In a number of instances quantities of 0.3 Gm. (four and one-half grains) in twenty-four hours have produced active poisoning. Phillips concludes that the single dose should never exceed 0.1 Gm. nor the daily dose 0.2 Gm.

Dose, one-half to three grains (0.03–0.2 Gm.).

PHENOL. U. S. (Br.)

PHENOL [Carbolic Acid]

"Phenol contains not less than 98 per cent. of C_6H_5OH." *U. S.* "Phenol, C_6H_6O, commonly termed carbolic acid, may be obtained from coal-tar oil." *Br.*

Acidum Carbolicum, *Br.*, also *U. S.* 1890; Acidum Phenicum; Acidum Phenylicum Crystallisatum; Phenic Acid, Phenylic Acid, Phenylic Alcohol, Phenic Alcohol, Benzophenol; Phénol, Acide carbolique, Acide Phénique, Hydrate de Phényle, *Fr.;* Acidum carbolicum, *P. G.;* Karbolsaure, Phenylsaure, Phenylalkohol, *G.;* Fenolo cristallizzato, Acido carbolico, *It.;* Acido fenico, *Sp.*

This important medicine was discovered in 1834, in the tar of coal, by Runge, who gave it the name of carbolic acid. When on the subject of its composition, we shall have occasion to show that, although more closely related chemically with the alcohols than the acids, it belongs to a peculiar class known in common as *phenols.* The U. S. P. (8th Rev.) dropped the names of Acidum Carbolicum and carbolic acid and adopted the correct title of Phenol for this substance. The British Pharmacopœia recognizes the name Acidum Carbolicum, but uses "phenol" as the English name for this substance.

Preparation.—For the commercial preparation of phenol the light oil fraction, from the distillation of coal-tar, is collected until a sample of the oil that runs from the still sinks in water. This fraction, with a sp. gr. of from 0.94 to 0.99, boils between 90° and 250° C. and contains from 4 to 10 per cent. of acids, and nearly all the true phenol which boils at 182° C. The oil from which the phenol is to be extracted is agitated with a weak solution of sodium hydroxide, 10 per cent. strength being strong enough. If a stronger solution is used many impurities, like naphthalene, are dissolved and contaminate the finished product. After agitation, the mixture, on standing, separates into two layers, the upper consisting of the extracted oil and the lower the solution of sodium phenolate. To this solution, after separation from the oily layer, an amount of hydrochloric or diluted sulphuric acid calculated from a special test with a small portion, as just sufficient, is then added in order to set the phenol free. It separates as an oily layer upon the surface, and, after being washed with a saturated solution of sodium chloride, is dried over calcium chloride and again distilled. The product thus obtained crystallizes out largely on a cooled surface, and, after removing the crystals from adhering liquid, and drying them by pressure, they are again submitted to the same process of distillation. Only by such a detailed procedure can phenol be separated from its homologues, like cresol (cresylic acid), $C_6H_4(CH_3)OH$, which accompany it, smell much like it, and boil between 185° C. and 200° C.

The unpurified liquors were formerly sold sometimes under the improper name of *coal tar creosote.* They were recognized in the U. S. Pharmacopœia, 1890 (*Acidum Carbolicum Crudum*), which was officially described as "a nearly colorless, or reddish, or brownish-red liquid, of a strongly empyreumatic and creosote-like odor; having a benumbing, blanching, and caustic effect upon the skin or mucous membrane; and gradually turning darker on exposure to air and light. The aqueous solution of Crude Carbolic Acid has a slightly acid reaction on litmus paper. In an aqueous solution of the Acid, bromine water produces a white precipitate. Crude Carbolic Acid should not be soluble in less than 15 parts of water at 15° C., and the aqueous solution should not have an alkaline reaction (absence of *alkalies*). If 50 volumes of the Acid be thoroughly agitated with 950 volumes of water, in a capacious vessel, on allowing the mixture to separate, the undissolved portion should not exceed 5 volumes, or 10 per cent. by volume of the acid (limit of other *less soluble constituents of coal-tar*)." *U. S.*, 1890. It is superior in germicidal power to pure phenol. (See *Cresol.*)

Phenol may be made synthetically in one of two ways—either from benzene, which is converted into *benzene-sulphonic acid,* the sodium salt of which is then fused with an excess of sodium hydroxide, producing sodium phenolate and sodium sulphite, from which, on the addition of sulphuric or hydrochloric acid, the phenol separates and may be distilled off; or a pure aniline oil is taken, neutralized with sulphuric acid, and to the acid solution sodium nitrite is added. The nitrous acid liberated forms at first *diazobenzene sulphate,* but this at once decomposes into phenol, sulphuric acid, and nitrogen, the reactions being as follows:

$$(C_6H_5NH_2)_2H_2SO_4 + 2HNO_2 = (C_6H_5N{=}N)_2SO_4 + 4H_2O$$

$$(C_6H_5N{=}N)_2SO_4 + 2H_2O = 2C_6H_5OH + H_2SO_4 + 4N$$

The practicability of manufacture of synthetic phenol by the above process was made possible by the great increase in price soon after the beginning of the European war. It is made in America by a number of manufacturing firms.

Description and Physical Properties.—Phenol, in its pure state, is a solid at ordinary temperatures, crystallizing in minute plates or long rhomboidal needles, white or colorless, of a peculiar odor recalling that of creosote, and an acrid burning taste. Its sp. gr. is 1.065. (Lemaire.) It is likely to become colored pinkish or brown under the influence of light and air. This reddening has been ascribed to various causes, such as ammonia and ammonium nitrite in the air, rust spots in tinned iron vessels, alkali in glass vessels, organic matter, etc. It is said to be due to oxidation; stannous chloride solution acquires a green color when shaken with the red colored phenol. Demant recommends the removal of the red color by adding to 89 parts of the melted substance 11 parts of alcohol, subjecting the mixture to freezing, and then draining off the portion remaining liquid. Perfectly white crystals can be thus obtained. A slight discoloration does not interfere with any of the medicinal uses of phenol. Phenol deliquesces on exposure, and becomes liquid, and the presence of water in the smallest proportion causes it to liquefy. It is customary to add 10 per cent. of water or glycerin to phenol for dispensing, as it is more convenient to use in a liquid form. Such a form is official (see *Phenol Liquefactum*). Its solution in glycerin is very useful, as the glycerite mixes with water very readily. (See *Glyceritum Phenolis.*) When diluted it has a sweetish taste with a slightly nauseating after-taste, and a faintly acid reaction. Although commonly called carbolic acid, its claims to be considered as an acid are very feeble; while it combines with salifiable bases, it is incapable of neutralizing the alkalies, and does not affect the color of litmus. Although it combines feebly with some bases, its salts are decomposed by carbon dioxide, and those with the alkalies have an alkaline reaction. The potassium phenolate is said to be decomposed even by water. Nitric acid converts it into picric acid, for the manufacture of which it is largely used. It reduces many metallic salts, especially those of silver and copper, and coagulates collodion. Shaken in the liquid form with one-fourth of water, and cooled at 4.5° C., it crystallizes in the form of a hydrate, $C_6H_5.OH + H_2O$, which fuses at 17° C.

" Colorless, interlaced, or separate needle-shaped crystals, or a white or light pink, crystalline mass. It has a characteristic, somewhat aromatic odor. When undiluted it cauterizes and whitens the skin and mucous membrane. One Gm. of Phenol is soluble in about 15 cc. of water at 25° C. It is very soluble in alcohol, glycerin, chloroform, ether, carbon disulphide, and in fixed or volatile oils. Soluble in petrolatum and in liquid petrolatum. When gently heated phenol melts, forming a highly refractive liquid. It is also liquefied by the addition of about 8 per cent. of water. Its vapor is inflammable.

" Congealing point: not below 39° C. Its aqueous solution yields with bromine water a white precipitate of tribromphenol, which at first redissolves, but becomes permanent as more of the reagent is added. Add 1 drop of ferric chloride T.S. to 10 cc. of an aqueous solution of Phenol (1 or 100): the liquid acquires a violet-blue color.

" An aqueous solution of Phenol (1 in 15) is clear, and neutral or only faintly acid to litmus paper. Heat about 5 Gm. of Phenol on a water bath: it is volatilized without leaving more than 0.05 per cent. of residue.

" Preserve in well-closed containers, protected from light." *U. S.*

" Small, colorless, deliquescent crystals; odor peculiar but not fetid or tarry; taste sweetish, pungent. Has a caustic action on skin and mucous membrane. Freely soluble in *alcohol* (90 per cent.), in *ether, chloroform, glycerin,* in the fixed and volatile oils, and in solutions of alkalies. Exposed to moist air it may acquire a pinkish tinge. At 15.5° C., 100 parts of Phenol are liquefied by the addition of 10 parts of *water,* form a clear liquid with 30 to 40 parts of *water,* and are completely dissolved by 1200 parts of *water.* The aqueous solution is clear and colorless. Melting point from 39° to 40° C.; boiling point not higher than 183° C. Specific gravity at the melting point 1.060 to 1.066. Phenol does not immediately redden *blue litmus paper.* Optically inactive. Coagulates *collodion* and *solution of albumen.* An aqueous solution of Phenol becomes deep purple with *T. Sol. of ferric chloride;* yields a white precipitate with excess of *solutions of bromine;* and when mixed with one-fourth of its volume of *solution of ammonia,* and then with a few drops of *solution of chlorinated soda,* becomes blue after a time, or immediately on gently heating. One volume of Phenol liquefied by the addition of 10 per cent. of *water,* forms with 1 volume of *glycerin* a clear liquid which is not rendered turbid by the addition of 3 volumes of *water* (absence of cresol). Evaporated on a water-bath it leaves not more than 0.1 per cent. of residue." *Br.*

Its solubility in water increases on heating the water; at 84° C. both liquids are miscible in all proportions. Its solution is, if pure, colorless, and remains so, but, if impure, is colored brownish by exposure. It is but slightly soluble in cold petroleum benzin.

Assay.—" Dissolve about 1.5 Gm. of Phenol, accurately weighed, in sufficient distilled water to make 1000 cc. Transfer an aliquot portion of this solution, containing from 0.038 to 0.041 Gm. of Phenol, to a 500 cc. glass-stoppered flask having a long, narrow neck, add 30 cc. of tenth-normal bromine, then 5 cc. of hydrochloric acid, and immediately insert the stopper. Shake the flask repeatedly during half an hour, allow it to stand for fifteen minutes, remove the stopper just sufficiently to introduce quickly 5 cc. of an aqueous solution of potassium iodide (1 in 5), being careful that no bromine vapor escapes, and at once stopper the flask. Shake the latter thoroughly, remove the stopper, and rinse it and the neck of the flask with a little distilled water, so that the washings may flow into the flask, then add 1 cc. of chloroform, shake the mixture well, and titrate with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal bromine corresponds to 0.001568 Gm. of C_6H_5OH." *U. S.*

For other methods of assaying Phenol, see *Chem News,* 1891, 74; *A. J. P.,* 1892, 164; *Ph. Centralh.,* 1892, 479; *D. C.,* 1896, 158; *A. J. P.,* 1898, 369.

The substances with which phenol is most likely to be confounded are cresol or cresylic acid and creosote, the former, like it, extracted from coal tar, the latter from wood tar exclusively. As cresol is incapable of crystallizing at ordinary temperatures, the two cannot be confounded in the solid state, and, as before observed, its presence in the liquid state is of little consequence, as its virtues are of the same kind, and at least equal. Its boiling point, however, is considerably higher than that of phenol, being about 204° C., and it may, therefore, be supposed to be present in any suspected liquid which will not crystallize at any common temperature, or boil under 202° C. to 204° C. It is also distinguished by being less soluble in water, ammonia water, glycerin, and solution of sodium hydroxide than is the case with phenol, but it is more soluble in petroleum benzin. Creosote is distinguished by its lower density, its liquid form, and its higher boiling point; by its insolubility in strong ammonia water, or in 6 per cent. sodium hydroxide solution, as well as its insolubility in pure glycerin (see *Creosotum*); by not coagulating collodion and albumin; and by the different effects on it of strong nitric acid, which with phenol produces pure picric or trinitrophenic acid, and with creosote, oxalic acid, resinous matter, and but a small portion of picric acid. Phenol differs also in having no effect on polarized light.

The commercial antiseptic preparations alleged to contain phenol often contain cresol and also nearly inactive and valueless neutral tar oils, and it is important to be able to determine the percentage of these different classes of constituents in a commercial sample. John Muter (*A. J. P.,* Nov., 1887, p. 581) has worked out a simple method for this, based upon the following four observed facts: (1) Phenol, cresol, and their homologues are completely soluble when shaken up with a 5 per cent. solution of sodium hydroxide; (2) Liquefied phenol and the corresponding cresol are insoluble in a saturated solution of chloride; (3) In the presence of a sufficient excess of alkali even a largely diluted solution may be boiled down without the slightest appreciable loss of phenol or cresol; (4) Tar oils and naphthalene are only very slightly dissolved by alkali, and may be perfectly removed from the solution by agitating it with benzene.

Uses.—Pure phenol is locally irritant, anesthetic and mildly caustic. When applied undiluted to the skin or mucous membrane it causes a sharp pain, followed by numbness, and accompanied by a whiteness and corrugation of the surface due to precipitation of albumen. In dilute solution, up to 3 or 4 per cent., it is only mildly irritant but is actively anesthetic and germicidal. In appropriate strengths phenol is a rapid and certain destroyer of the vegetative forms of bacteria, but against the more resistant spores it is comparatively useless. An 1 per cent. solution will destroy non-sporulating micro-organisms after sufficiently prolonged exposure, and a 2 per cent. solution promptly. On the other hand, the anthrax spores are not killed with certainty even after twenty-four hours' exposure to a 5 per cent. solution. It is antiseptic—that is, inhibits the multiplication of bacteria—when present in the proportion of about 1 to 800. Its peculiar value as a germicide is due largely to the fact that its activity is but slightly diminished by the presence of albuminous material. Although in sufficient concentration phenol precipitates albumen, it does not do so by forming chemical union with it, as does bichloride of mercury, but by changing the character of the solvent; the precipitation is analogous to that which takes place when water is added to an alcoholic solution of resin. Partly because of the wide-spread familiarity with phenol and partly for certain technical reasons it has been adopted by the United States Government as a standard for comparison of disinfectant power. The *phenol coefficient* of the United States Government (*Hygienic Lab. Bulletin* No. 82, April, 1912) represents the amount of phenol required to exercise the same degree of germicidal action against the typhoid bacillus, under certain standard conditions of testing, as one part of the disinfectant to be tested; for instance, if disinfectant X has a phenol coefficient of 2 that means that it would require 2 parts of phenol to equal one of X, or in popular parlance that X is twice as strong as phenol; a phenol coefficient of 0.5 means that the disinfectant is only one-half as active as phenol.

There has been much theorizing concerning the effects of various solvents on the germicidal power of phenol. McMaster has shown that while a solution of phenol in vegetable oil is almost without germicidal power, a 1 per cent. solution in liquid petrolatum is very active. Wilbert (*U. S. Pub. H. Rep.,* April 28th, 1916) finds that the presence of alcohol or glycerin does not lessen the germicidal effects of aqueous solutions.

Phenol is widely used as a disinfectant not only for sanitary but for surgical and medical purposes. For the disinfection of the surgeon's hands its local anesthetic action is a great disadvantage and its uncertain effect upon sporulating organisms almost excludes its use for the disinfecting of surgical instruments. As a dressing for *wounds* it is, however, very widely employed. In *burns* and other painful *ulcerations* its local anesthetic action often makes it peculiarly valuable. When applied continuously for several days it in some way interferes with the nutrition of the part, and a number of cases of local gangrene have followed the use of phenol dressings. Chlunsky (*Cb. I. M.,* 1912, p. 226) asserts that the addition of camphor lessens the caustic action of phenol and has employed a mixture containing 30 parts of phenol, 60 of camphor, and 10 of alcohol, as a local application in the treatment of *erysipelas.* This *phenol-camphor* (which is also known under the name of *kamphenol* and *erypol*), has also been used by a number of surgeons as a local application to infected wounds, furuncles, and as an injection into *cold abscesses,* with asserted excellent results. According to Horowitz (*D. M. W.,* 1913) the diminution of the corrosive action of the phenol is due to the action of the alcohol rather than to the camphor. Phenol is also used to a large extent in the form of oily or watery solutions in the treatment of *coryza, stomatitis,* and other infected conditions of the mucous membranes.

For ordinary surgical purposes it may be used in strengths of from 3 to 5 per cent. The liquid phenol is often applied undiluted as a germicide and caustic in badly infected wounds.

For burns and scalds 1 part of phenol in 6 parts of olive oil may be applied on lint. For the dressing of *cancerous* and other foul *ulcers,* a cerate (ten grains to the ounce) may be used. There is an official ointment.

Phenol is frequently employed as an antiseptic in various forms of gastro-intestinal affections. Because of the rapidity of its absorption as well as the relatively large dose which would be required, it is doubtful whether it exercises any efficient action in the intestines, but in fermentative *gastritis* it is often a useful remedy. It is also of service in *nervous vomiting,* and in *gastrodynia* for its local anesthetic action upon the mucous membrane of the stomach. Externally it is of much service as a local anesthetic in *urticaria, sunburn,* and other conditions attended with *itching* or burning of the skin.

In 1899, Baccelli reported very favorably on the hypodermic injection of phenol for the treatment of *tetanus* (see H. C. Wood, Jr., *M. A.,* 1899, i, p. 191). Although Courmont and Doyon (*Neurol. Centralbl,* 1899) in a research upon experimental tetanus in the lower animals, were unable to note any beneficial action, the method is still reported on favorably by various writers (see *J. A. M. A.,* 1915, lxiv, pp. 278, 1266, and 1918, lxxi, p. 2125).

The method consists in injecting hypodermically two or three cc. (30–45 minims) of a 2 per cent. solution every two or three hours, a total dose of 0.5 to 1.5 Gm. (eight to twenty-three grains) of phenol being given in the twenty-four hours.

Phenol Poisoning.—Because of the ease with which it is obtained and the rapidity and certainty of its effects, phenol is a very frequently used poison for suicidal purposes, and cases of accidental poisoning are also quite common. The symptoms usually develop very rapidly; indeed death has occurred in 2 or 3 minutes, the patient dying in immediate coma and collapse. After small amounts the symptoms are nausea and vomiting, collapse with pallor and cold sweats, feeble pulse, stupor deepening into complete insensibility and disturbances of the breathing, the respirations are usually hurried and shallow, often irregular and sometimes paroxysmally arrested. There is usually paralysis of both sensation and motion, but in some cases violent epileptiform convulsions have occurred. The urine is generally scanty and albuminous and of a greenish or blackish color. The diagnosis is usually not difficult, being made upon the odor, the smoky urine, and the presence of white corrugated spots in the mucous membrane of the mouth or throat. The ordinarily fatal dose of phenol is about half an ounce, but De Vries (*Th. M.,* 1890, iv, p. 644), has reported death in a woman from 22 grains. On the other hand, recovery has followed after the ingestion of an ounce. In the fatal cases death usually occurs in less than 2 hours from respiratory failure, although in some instances weakness of the heart has been the cause of the lethal termination.

In the treatment of carbolic acid poisoning the stomach should be immediately emptied, preferably by means of the stomach pump. There is no efficient chemical antidote known for phenol. Alcohol which is useful for the treatment of local injuries by carbolic acid, probably acts simply because being an excellent solvent it mechanically removes the poison; in the stomach, it may increase the absorption of the phenol and be harmful rather than beneficial. It was at one time supposed that the sulphates would unite with a poison to form innocuous phenol sulphonates. Although there is evidence that the sulphates may be useful in carbolic acid poisoning, their action is not a chemical one. Macht (*J. H. H. B.,* 1915, xxvi, p. 98) advises washing out the stomach with a strong solution of sodium sulphate. Isaacs (*Ohio State M. J.,* 1922, xviii, p. 558) recommends the following treatment: the stomach is washed out with three to six quarts of a 5 per cent. solution of sodium bicarbonate, afterwards from 60 to 120 cc. of a 50 per cent. solution of magnesium sulphate is left in the stomach. The urine is kept alkaline by the administration of bicarbonate and citrate of soda. Pain in the alimentary tract, due to the local caustic action of the drug, is relieved by the use of orthoform or occasionally morphine may be necessary. Stimulation by the use of caffein-sodium benzoate hypodermically, and by the external application of heat, is applied as necessary. The patient should be kept in bed until signs of hemorrhage and renal irritation have disappeared.

Dose, one to three grains (0.065–0.2 Gm.).

PHENOL LIQUEFACTUM. U. S. (Br.)

LIQUEFIED PHENOL Phenol Liq. [Liquefied Carbolic Acid]

"Phenol liquefied by mixing with 10 per cent. of water. It contains not less than 88 per cent. of C_6H_5OH." *U. S.*

Acidum Carbolicum Liquefactum, *Br.;* Liquefied Carbolic Acid; Acidum carbolicum liquefactum, *P. G.;* Verflüssigte Karbolsäure, *G.;* Fenolo liquido, *It.;* Acido Fenico liquido, *Sp.*

"Phenol, a convenient quantity, distilled water, a sufficient quantity. Liquefy the phenol by placing the unstoppered container in a water bath and apply heat gradually until it is melted. Transfer the liquid to a tared vessel, weigh, and add 1 Gm. of distilled water for each 9 Gm. of phenol and mix thoroughly." *U. S.* "Phenol, 100 *grammes;* Distilled Water, sufficient to produce 115 *grammes.* Mix." *Br.*

Description and Physical Properties.—"A colorless liquid, which may develop a red tint upon keeping. It has a characteristic, somewhat aromatic odor. When undiluted it cauterizes and whitens the skin and mucous membrane. Liquefied Phenol is miscible with alcohol, ether, and glycerin. When diluted with an equal volume of glycerin, the mixture is miscible with water.

"Specific gravity: about 1.065 at 25° C. When subjected to distillation, the boiling point does not rise above 182° C. In other respects Liquefied Phenol responds to the tests for identity and purity under *Phenol,* omitting the congealing point.

"**Assay.**—Proceed as directed under *Phenol.*" *U. S.*

"NOTE.—When Phenol is to be mixed with collodion, fixed oils, liquid petrolatum, or petrolatum, use melted crystalline phenol instead of Liquefied Phenol.

"Preserve in well-closed containers, protected from light." *U. S.*

"A liquid, at first colorless, but usually acquiring a pinkish hue. Forms a clear solution on the addition of 12 to 20 per cent. by weight of *water* at 15.5° C. Specific gravity 1.067 to 1.069. Boiling point gradually rising to a temperature not higher than 183° C." *Br.*

For uses, etc., see under *Phenol.*

Dose, one to three minims (0.06–0.2 cc.)

Off. Prep.—Glyceritum Phenolis, *U. S.;* Unguentum Phenolis, *U. S.;* Aqua Phenolata, *N. F.;* Liquor Iodi Phenolatus, *N. F.;* Liquor Sodii Boratis Compositus, *N. F.*

PHENOLPHTHALEINUM. U. S., Br.

PHENOLPHTHALEIN Phenolphthal.

"$(C_6H_4OH)_2CO.C_6H_4CO$" *U. S.*

"Phenolphthalein, or dihydroxy-diphenylphthalide, $C_{20}H_{14}O_4$, may be obtained by heating phenol with phthalic anhydride and sulphuric acid, and purifying the product." *Br.*

Phenolphthalein is made by heating phenol, 10 parts, phthalic anhydride, 5 parts, and sulphuric acid, 4 parts, for a number of hours to 120° C. The sulphuric acid acts merely as a dehydrating agent and is subsequently removed by washing with water. The crude phenolphthalein is subsequently purified by dissolving in an alkali, precipitating with an acid and then dissolving in alcohol and decolorizing with animal charcoal. It may be recovered from the alcohol by evaporation or precipitated by diluting the solution with water. The reaction for its formation is as follows:

$$2C_6H_5OH + C_6H_4(CO)_2O = (C_6H_4OH)COC_6H_4CO + H_2O$$

Phenolphthalein has feebly acidic properties and is capable of uniting with metals to form salts. The salts so formed are soluble in water and of a deep red color. For this reason phenolphthalein is widely used in the detection and estimation of alkalies. (See *Phenolphthalein T.S.,* Part III.)

Description and Physical Properties.—"A white or faintly yellowish-white, crystalline powder. It is odorless, and is stable in the air. Phenolphthalein is almost insoluble in water. One Gm. is soluble in 13 cc. of alcohol, and in about 70 cc. of ether, at 25° C.

"Melting point not below 256° C. It is readily dissolved by solutions of alkali hydroxides and by hot solutions of alkali carbonates, yielding a red liquid. These solutions are decolorized by the addition of an excess of acid.

"Ash: not more than 0.05 per cent. A solution of 0.5 Gm. of Phenolphthalein in 30 cc. of neutral alcohol is colorless. One-half Gm. of Phenolphthalein dissolves completely in a mixture of 4 cc. of sodium hydroxide T.S. and 50 cc. of distilled water (*fluorane*). A mixture of 250 cc. of cold, recently boiled, distilled water and 0.5 cc. of a solution of Phenolphthalein (1 in 100) in alcohol, requires not more than 0.25 cc. of fiftieth-normal sodium hydroxide to produce a pink color. Heat 0.5 Gm. of Phenolphthalein with 10 cc. of diluted hydrochloric acid on a water bath for five minutes, filter, and evaporate the filtrate to dryness. The residue dissolved in 25 cc. of distilled water, slightly acidulated with hydrochloric acid, meets the requirements of the test for *heavy metals,* Heat a crucible to redness, and introduce, in small portions, an intimate mixture of 0.2 Gm. of Phenolphthalein, 0.5 Gm. of potassium nitrate, and about 0.3 Gm. of anhydrous sodium carbonate. Maintain a red heat until the reaction ceases, then boil the cooled residue for five minutes with 10 cc. of diluted sulphuric acid, filter, and wash the undissolved residue with 10 cc. of distilled water. Evaporate the filtrate and washings until sulphuric acid vapors begin to evolve. The residue dissolved in 5 cc. of distilled water conforms to the requirements of the test for *arsenic*." *U. S.*

"A white, or yellowish-white, crystalline or amorphous powder. No odor or taste. Soluble in *alcohol* (90 per cent.), the solution being colorless. Almost insoluble in *water*, but soluble in *solution of sodium hydroxide*, forming an intensely red liquid. Melting point 250° to 253° C. Not more than 0.1 millilitre of *N/10 solution of sodium hydroxide* is required to produce a red coloration in 250 millilitres of recently boiled and cooled *water* to which has been added 0.5 millilitre of a solution (1 in 100) of Phenolphthalein in *alcohol* (60 per cent.). No appreciable ash." *Br.*

Uses.—The discovery that phenolphthalein possessed cathartic properties was made accidentally; it was used in Hungary as a means for the ready identification of artificial wines, and the observation that these wines were laxative led to an investigation of its properties. H. C. Wood, Jr. (*J. A. M. A.*, 1911, liv, p. 248), has found that it increases intestinal secretions, and that, when given intravenously to dogs in doses equivalent to 60 grains for a man, it produced no change in circulation or respiration. According to Berthomeau and Daguin (*Press Med.*, 1908, xvi, p. 378), the cathartic effects are due to combined stimulation of secretion and peristalsis. Although it seems to be slightly irritant to the kidneys when introduced into the blood stream, there is little danger of this action because of its slight absorbability by the bowel. It is not uncommon, however, for the urine of patients taking phenolphthalein to give a pinkish reaction with the alkalies.

Hydrick (*J. Bi. Chem.*, 1914, xvii) found albuminuria in every one of twenty experiments after the administration of 1 to 2 grain doses of phenolphthalein, but the results are so contrary to common experience that one is tempted to doubt the accuracy of his observations. Orland (*Med. Klin.*, 1913, p. 257) reported a case of a child aged three years who took 1.8 Gm. (27 grains) in the form of tablets with no more serious effect than violent purgation. The urine for four days showed the presence of phenolphthalein, but showed neither albumin nor sugar.

Several cases of dermatitis following the use of phenolphthalein as a laxative have been reported (see Corson and Sidlick, *J. A. M. A.*, 1922, lxxviii, 882).

Phenolphthalein is a mildly acting cathartic, usually requiring from 4 to 8 hours for catharsis, and producing large, soft discharges without much griping. Although when used continuously the alimentary canal seems to become accustomed to it, it is nevertheless useful as a variant from the vegetable laxatives in chronic as well as in the more occasional types of *constipation*. Phenolphthalein, in a more or less pure state, is the basis of a large number of proprietary aperients. Among these are: *Exlax, laxine, laxoin, laxatol, laxothalen, laxaphen, probilin, phenolax, phenalein, probilin, purgen, purgalax,* etc.

Dose, one-half to three grains (0.032–0.2 Gm.).

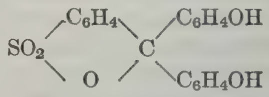
Off. Prep.—Tabellæ Phenolphthaleini, *N. F.*

PHENOLSULPHONPHTHALEINUM. U. S.

PHENOLSULPHONPHTHALEIN Phenolsulphonphthal. [Phenol Red]

"$(C_6H_4OH)_2CO.C_6H_4SO_2$." *U. S.*

This product of the reaction of phenol and sulphobenzoic acid anhydride differs from phenolphthalein in containing an SO_2 group in place of the CO group. It has the following structural formula:



The anhydride of o-sulphobenzoic acid is first prepared by distilling the free acid obtained from the acid ammonium salt with P_2O_5. The acid ammonium salt may be prepared from commercial saccharin. By the fusion of o-sulphobenzoic anhydride with phenol, the phenolsulphonphthalein is produced.

In neutral media, either aqueous or alcoholic it gives yellow solutions, but in the presence of alkalies it forms red solutions similar to those of phenolphthalein but usually not quite so purple.

Description and Physical Properties.—"A crystalline powder, varying in color from bright to dark red. It is stable in the air. One Gm. of Phenolsulphonphthalein is soluble in about 1300 cc. of water, 350 cc. of alcohol, and in 500 cc. of acetone. It is almost insoluble in chloroform and ether.

"It is readily soluble in solutions of alkali hydroxides and carbonates as well as in ammonia water, and in solutions of ammonium carbonate, with a color varying from deep red in concentrated solutions to a violet-tinted red in dilute solutions. The red color is changed to orange or yellow by a slight excess of acid. Its solution in alkali hydroxides is decolorized by warming with zinc dust.

"Dried to constant weight at 110° C., Phenolsulphonphthalein loses not more than 1 per cent. Ash: not more than 0.2 per cent. Fill a 100 cc. glass-stoppered flask with thoroughly boiled and cooled distilled water to within a few cc. of the stopper. Add 1 cc. of an alcoholic solution of Phenolsulphonphthalein (1 in 1000) and 0.5 cc. of fiftieth-normal sodium hydroxide, stopper immediately, and mix well: a strong red color is produced (*sensitiveness*). To about 1 Gm. of Phenolsulphonphthalein, accurately weighed, add a filtered solution of 0.5 Gm. of sodium bicarbonate in 20 cc. of distilled water. Rotate frequently during one hour, dilute to 100 cc., and let stand over night.

Filter through counterbalanced filters or a Gooch crucible, wash at first with 25 cc. of a 1 per cent. solution of sodium bicarbonate, then with 25 cc. of distilled water, and dry to constant weight at 110° C.: the weight of the insoluble residue does not exceed 0.2 per cent. Heat a crucible to redness, and introduce, in small portions, an intimate mixture of 0.2 Gm. of Phenolsulphonphthalein, about 0.5 Gm. of potassium nitrate, and about 0.3 Gm. of anhydrous sodium carbonate. Maintain a red heat until the reaction ceases, boil the cooled residue for five minutes with 10 cc. of diluted sulphuric acid, filter, and wash the undissolved residue with 10 cc. of distilled water. Evaporate the filtrate and washings until sulphuric acid vapors begin to evolve: the residue dissolved in 5 cc. of distilled water meets the requirements of the test for *arsenic.*" *U. S.*

Uses.—Phenolsulphonphthalein is used only as a diagnostic reagent. It was brought forward by Geraghty and Rowntree (*J. A. M. A.,* 1911, lvii, p. 811) as a test for the functional capacity of the kidney. The determination is carried out as follows: Half an hour after having drunk a glass of water the bladder is emptied and one-tenth of a grain (0.006 Gm.) of phenolsulphonphthalein dissolved, with the aid of small amount of sodium bicarbonate in fifteen minims (1.0 cc.) of water is injected intramuscularly. The urine may be collected either by having the patient micturate at the end of fifteen minutes or better by leaving a catheter in the bladder and allowing the urine to drain through the catheter into a vessel containing a drop of a 25 per cent. solution of sodium hydroxide until the appearance of a pinkish tint. This time is noted and the catheter withdrawn. Subsequently the urine is collected at one hour and two hours after the ingestion, and after this it is saved for twenty-four hours. The quantity of the dye in the urine is determined by alkalizing with sodium hydroxide, diluting accurately up to one liter and comparing the depth of color with a standard solution of phenolsulphonphthalein. Various instruments to facilitate this part of the test are on the market. In health the dye appears in the urine within five or ten minutes, about one-half of the dose is eliminated in the first hour and 75 or 80 per cent. in two hours. In cases of *nephritis* the elimination is more or less delayed according to the character of the lesion. While a normally rapid elimination may be accepted as conclusive evidence of the functional capacity of the kidneys, we believe that slight reductions in the rapidity of elimination should be interpreted with some conservatism. It may be remarked in this connection that the preservation of function is no proof that the kidney is perfectly healthy. It simply means that there is enough healthy kidney structure to perform the necessary eliminating functions of this organ.

Dose, one-tenth of a grain (0.006 Gm.).

PHENYLIS SALICYLAS. U. S. (Br.)

PHENYL SALICYLATE Phenyl. Salicyl. [Salol]

"$C_6H_4(OH)COOC_6H_5$ 1:2." *U. S.* "Salol, or phenyl salicylate, $C_{13}H_{10}O_3$, may be obtained by the interaction of salicylic acid and phenol." *Br.*

Salol, *Br., U. S.* 1890; Phenolum Salicylicum, *Fr. Cod.;* Salicylate de Phényle, *Fr.;* Phenylum salicylicum, *P. G.;* Phenylsalicylat, Salicylsaurephenylester, *G.;* Salol, *It.;* Salicilato de fenol, *Sp.*

Preparation.—Phenyl salicylate was first produced by Nencki, of Basel, and introduced to the medical profession by Sahli, of the same place. It is prepared by heating salicylic acid with phenol in the presence of phosphorus pentachloride or phosphorus oxychloride. According to Ernert, nearly the theoretical yield of phenyl salicylate may be obtained by heating salicylic acid to a temperature between 160° and 240° C., and preventing the access of air while water is being disengaged; it is probable that salicylic anhydride is formed, and the phenyl resulting from its decomposition combines with unaltered salicylic acid to produce phenyl salicylate according to the following reaction:

$$2C_6H_4OHCOOH = (C_6H_4OHCO)_2O + H_2O$$

Then

$$(C_6H_4OHCO)_2O = C_{13}H_{10}O_3 + CO_2$$

Description and Physical Properties.—"A white, crystalline powder, having an aromatic odor, and a characteristic taste. One Gm. of Phenyl Salicylate is soluble in 6670 cc. of water and in 6 cc. of alcohol, at 25° C. It is very soluble in chloroform, ether, benzene, and in fixed or volatile oils.

"It melts between 41° and 43° C. Heat about 0.3 Gm. of Phenyl Salicylate with 3 cc. of sodium hydroxide T.S. for a few minutes and then acidify the solution with hydrochloric acid: salicylic acid separates and the odor of phenol is recognizable. The addition of diluted ferric chloride T.S. to an alcoholic solution of the salt (1 in 20) produces a violet color.

"Phenyl Salicylate does not redden moistened blue litmus paper (*free acid*). Ash: not more than 0.05 per cent. Shake 1 Gm. of Phenyl Salicylate with 50 cc. of distilled water and filter the liquid: the addition of 1 drop of ferric chloride T.S. to 10 cc. of the filtrate produces no violet color (*uncombined phenol or salicylic acid*). Ten cc. portions of the filtrate prepared for the preceding test, when tested separately with barium nitrate T.S. and silver nitrate T.S., show no turbidity (*sulphate or chloride*).

"Preserve in well-closed containers, in a cool place." *U. S.*

"Colorless crystals, or crystalline powder. Aromatic odor; taste slight. Almost insoluble in *water;* soluble in 15 parts of *alcohol* (90 per cent.), in 0.3 part of *ether* or of *chloroform,* and in fixed and volatile oils. Melting point from 42° to 43° C. Alcoholic solution neutral to *litmus;* yields a white precipitate with *solution of bromine,* and a violet coloration with dilute *T. Sol. of ferric chloride.* When 0.2 gramme is boiled with 5 millilitres of *solution of sodium hydroxide,* and the cooled solution acidified with *hydrochloric acid,* the odor of phenol is developed and a crystalline precipitate is formed. *Water* which has been shaken with Salol is not affected by *T. Sol. of ferric chloride* (absence of free salicylic acid and of readily soluble salicylates), and yields no characteristic *reactions* for sulphates or chlorides. No appreciable ash." *Br.*

Uses.—In the small intestine phenyl salicylate is broken up by the pancreatic juice, and yields about thirty-six per cent. of phenol and sixty-four per cent. of salicylic acid. The completeness and rapidity of this action depend upon the amount of phenyl salicylate ingested and the alkalinity of the juice in the intestines. The change is, however, sufficient, when phenyl salicylate is freely given, for the production of salicylic acid intoxication, and for the blackening of the urine with educts from phenol. Because this change occurs in the intestines somewhat slowly, the remedy has been used as an internal antiseptic in the treatment of *enteritis* and *intestinal fermentation,* but its value is questionable. It has been largely used in *rheumatism* as a substitute for salicylic acid, but it is much less prompt and certain in its action than is that remedy. Moreover, on account of the large proportion of phenol which it contains, it is much more dangerous than the corresponding dose of salicylic acid. Hesselbach has shown that it is prone to affect the secreting structure of the kidneys, and two fatal cases of poisoning by it have been reported. (*L. L.,* May, 1891.) It is especially dangerous when the kidneys are diseased. Phenyl salicylate is used as a test of gastric motility, the time required for the appearance of salicylic acid in the urine depending largely upon the rapidity with which it passes out of the stomach. It has also been employed as a surgical dusting powder on the basis that it will be slowly decomposed by the wound secretions, liberating its antiseptic constituents.

Dose, from five to fifteen grains (0.3–1.0 Gm.).

PHOSPHORUS. U. S., Br.

PHOSPHORUS Phosphor.

"The yellow allotropic form of phosphorus [P]." *U. S.* "Phosphorus is a solid nonmetallic element. It may be obtained from calcium phosphate." *Br.*

Phosphore, *Fr. Cod.;* Phosphorus, *P. G.;* Phosphor, *G.;* Fosforo, *It., Sp.*

This non-metallic element was discovered in 1669 by Brandt, an alchemist of Hamburg, who obtained it from evaporated urine by a process which remained a secret until 1737. As thus procured, it was exceedingly scarce and costly. In 1769 the Swedish chemist Gahn discovered it in bones, and shortly afterwards published a process by which it might be extracted.

The process in brief consisted in digesting powdered calcined bones with sulphuric acid which changed the basic calcium phosphate into the acid phosphate. The latter by the action of heat was transformed into the metaphosphate $(CaPO_3)_2$ and this by heating in a retort, in the presence of charcoal, was decomposed, the phosphorus passing over as a distillate.

The manufacture of phosphorus by the use of the electric furnace, first brought out by Readman and Parker some years ago, has now practically displaced the older methods for the production of phosphorus. Albright and Wilson, who formerly manufactured phosphorus by the distillation method at Oldbury, England, have built works at Niagara Falls, and practically control the production by the electric furnace method in the United States and England. A mixture of calcium phosphate, carbon, and sand or kaolin is submitted to the temperature of the electric arc while packed in a covered plumbago crucible. The phosphorus is then distilled off in a current of an inert gas. It is very pure, and it is claimed that 86 per cent. is recovered. The native Redonda phosphate, an aluminum phosphate, is also taken for this process instead of the calcium phosphate, and phosphorus obtained from it without any previous purification. The great bulk of the phosphorus is consumed in the manufacture of matches, a smaller amount in the production of phosphor bronze, and another portion in making the chemical compounds of the element.

When perfectly pure it is colorless, but as usually prepared it is yellowish or reddish yellow. It is flexible, and when cut exhibits a waxy luster.

Description and Physical Properties.—"A translucent, nearly colorless solid, having a waxy luster, and a consistence at ordinary temperatures about that of beeswax. After long keeping the surface becomes white or red, and occasionally black. It has a distinctive and disagreeable odor. One Gm. of Phosphorus is soluble in about 400 cc. of dehydrated alcohol, in about 40 cc. of chloroform, 102 cc. of absolute ether, 31.5 cc. of benzene, and in 0.9 cc. of carbon disulphide, at 25° C. It is sparingly soluble in fixed oils, and is practically insoluble in water, to which it imparts its characteristic, disagreeable odor and taste. Specific gravity: about 1.830 at 10° C.

"When exposed to the air, Phosphorus emits white fumes, which are luminous in the dark, and have an odor somewhat resembling that of garlic. On longer exposure to the air, it often takes fire spontaneously.

"Add 1 Gm. of Phosphorus to 10 cc. of nitric acid diluted with 10 cc. of distilled water in a flask having a capacity of 50 cc. Digest the mixture at a gentle heat on a water bath until the Phosphorus is dissolved, maintaining an atmosphere of carbon dioxide in the flask during the heating. Transfer this solution to a dish, evaporate until nitrous vapors are no longer given off, and then dilute the solution to 250 cc. with distilled water. One cc. of this solution meets the requirements of the test for *arsenic.* A 50 cc. portion of the latter solution shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid.

"Preserve carefully under water, in strong, well-closed containers, in a secure and moderately cool place, protected from light." *U. S.*

"A semi-transparent, wax-like solid, which emits white vapors and is luminous in the dark when exposed to the air. Insoluble in *water;* soluble in 350 parts of *absolute alcohol,* in 80 parts of *olive oil,* in 80 parts of *ether,* in 25 parts of *chloroform,* and in 0.5 part of *carbon disulphide.* Soft and flexible at ordinary temperatures. Melting point 44° C. Ignites in the air at a temperature a little above its melting point, burns with a luminous flame and produces dense white fumes. 1 gramme is slowly attacked and finally dissolved without residue when boiled with 10 millilitres of *nitric acid* diluted with an equal volume of *water,* and the resulting solution yields not more than the slightest *reaction* for sulphates." *Br.*

Its pulverization may be readily effected by melting it in hot water, and agitating until it is thoroughly cooled; a finer powder is obtained with saline solutions than with pure water.

Phosphorus boils at 287.7° C., air being excluded. During its combustion it combines with the oxygen of the air, and forms phosphoric oxide. On account of its great inflammability, it must be kept under water. When exposed to the air it undergoes a slow combustion, emitting white vapors, which are luminous in the dark. It sometimes contains arsenic, and therefore, when used in forming medicinal preparations, should be tested for that metal. It occasionally contains antimony or sulphur, the latter rendering it brittle.

When phosphorus is kept in ordinary water it becomes covered with a whitish layer. This layer of *white phosphorus,* as it is sometimes called, appears to be due to partial oxidation by the free oxygen held in solution by the water. The change never takes place in water entirely deprived of air, and the water when it has taken place holds phosphorous acid in solution.

Schroetter, of Vienna, in 1845 discovered an allotropic form of phosphorus, which he called *red* or *amorphous phosphorus.* It is formed when ordinary phosphorus is kept long at a temperature between 215° C. and 250° C., in atmospheres which have no action on it, or in closed glass tubes. Red phosphorus is a reddish-brown powder having a sp. gr. of 2.19. It is insoluble in carbon disulphide and in all of the solvents in which ordinary phosphorus is soluble. In marked contrast to the affinity of yellow phosphorus for oxygen, it is practically permanent in the air although it does undergo slight oxidation after sufficiently long exposure. Solidified from the fused state, it is brittle, and breaks with a conchoidal fracture. Its hardness is considerable. Commercial red phosphorus usually contains more or less of the yellow form, from which it may be freed by carbon disulphide—which dissolves the ordinary variety and leaves the allotropic as a deep red amorphous powder—or by boiling in a solution of hydroxide—which dissolves the yellow phosphorus. It may also be purified by shaking it with a solution of calcium chloride of a density intermediate between that of red and that of ordinary phosphorus, and with a little carbon disulphide. The red variety will sink to the bottom, and the ordinary float on top of the solution, dissolved in the disulphide. (E. Nicklés.) Red phosphorus, when pure, is not poisonous and has, therefore, entirely replaced the poisonous yellow variety in the manufacture of friction matches. The use of the yellow for this purpose is legally forbidden in most civilized countries.

There are other allotropic modifications of phosphorus known but are of little practical interest and the reader is referred to works on chemistry.

Phosphorus forms with oxygen two oxides, *phosphoric,* P_2O_5, and *phosphorous,* P_2O_3. Corresponding to the first of these are three acids, known as *orthophosphoric* (tribasic phosphoric), H_3PO_4, *pyrophosphoric,* $H_4P_2O_7$, and *metaphosphoric,* HPO_3. The first of these is formed by dissolving P_2O_5 in boiling water, or by the action of nitric acid upon phosphorus itself; the second by the heating of the tribasic phosphoric acid to 213° C., and the third by the ignition of the tribasic variety, or by dissolving P_2O_5 in cold water. To the second oxide corresponds *phosphorous acid,* H_3PO_3, although it cannot be formed directly from the oxide. This is a dibasic acid, containing one hydrogen atom not replaceable by metal. To the hypothetical *hypophosphorous oxide,* P_2O, corresponds *hypophosphorous acid,* H_3PO_2. It is monobasic, containing two hydrogen atoms which are not replaceable by metal.

Phosphorus is frequently used as an ingredient in rat pastes. A method for the determination of the free phosphorus in such preparations as well as in the phosphoretted resin, tablets, pills, etc., has been described by E'we and Vanderkleed (*J. A. P. A.*, 1914, p. 1684), in which the phosphorus is distilled in an atmosphere of CO_2, and the distillate collected in a silver nitrate solution and the resulting silver compound decomposed and the phosphorus estimated in the ordinary manner.

Uses.—The continued use of small doses of phosphorus stimulates the blood-making organs, but especially the growth of bone. When administered to growing animals the spongy tissue of the bone becomes thickened and the compact tissue more dense. That phosphorus affects the growth of bones in young animals was first proven in 1872 by Wegner who found that the administration to calves caused a thickening of the compact layer of bone especially along the epiphyseal lines. His results as far as the lower animals are concerned have been confirmed by several investigators, and Phemister (*J. A. M. A.*, 1921, lxxvi, p. 850) by means of the X-ray has shown that a similar change occurs in the bones of children. There is some evidence also that it has a tonic effect upon the nervous system. Phosphorus is used in medicine in the treatment of diseases of the osseous tissues, such as *rickets, ununited fracture,* and *osteomalacia.* It is also widely employed in corrections of nervous exhaustion, such as *neurasthenia* and some types of *neuralgia.* It is even believed by some to be of service in degenerative conditions of the nervous system, and has been used in *brain softening,* but with less positive results. Leubuschur (*M. M. W.*, 1913, xxx, p. 494) lauds it in the management of *epilepsy.* It has also been asserted to be of benefit in certain *skin diseases,* notably *acne, psoriasis,* and *chronic eczema.* It might be well to emphasize that the action of elemental phosphorus is not possessed by phosphoric acid and there is no convincing evidence that either the organic or inorganic phosphates possess the same kind of influence over the metabolism.

Phosphorus Poisoning.—Phosphorus is a very virulent poison, as little as one-eighth of a grain having proven fatal, and an infant was killed by eating the heads of two old-fashioned friction-matches. Since the prohibition of the manufacture of yellow phosphorus matches phosphorus poisoning has become very rare but an occasional case from *roach-poison,* or other vermin exterminator may occur. The symptoms usually do not manifest themselves until some hours after the ingestion of the phosphorus. General malaise then becomes very pronounced, and is soon accompanied by nausea, abdominal pain, and vomiting of food, mucus, and bile. On the second and third day the vomiting is likely to cease, but the abdominal tenderness remains, and there is some fever. Later the patient becomes jaundiced and severe vomiting of a coffee-ground liquid, free from bile and similar to the black vomit of yellow fever, may set in; the urine is scanty and albuminous, often with tyrosine and leucine in it, or it may finally be suppressed. Frequently there is wild delirium. The temperature falls markedly, and the patient sinks into a coma which ends in death. After death a peculiar fatty degeneration is found affecting almost all the soft tissues. The parts which suffer first are the liver, the gastro-intestinal mucous membrane, and the kidneys. Both in its symptoms and in its lesions phosphorus poisoning so closely resembles acute atrophy of the liver that only by detecting the phosphorus in the matters vomited, in the excretions, or in the tissues of the body, can a positive diagnosis be made. As the phosphates are normally abundant in the urine it is necessary to find the phosphorus in the elemental state.

For methods of detecting phosphorus in cases of suspected poisoning, see *U. S. D.*, 19th ed., p. 935.

It is evident from the widespread lesions caused by phosphorus that after its absorption no treatment can be of service. It is therefore of the utmost importance that chemical antidotes and emetics be used promptly. Probably the best chemical antidote is potassium permanganate, which acts by oxidizing the poison, but copper sulphate is of great value as it not only forms a non-toxic phosphide of copper but also acts as an emetic. The oil of turpentine has been stated to possess antidotal properties, but this is not true of the American oil. If the stomach tube be at hand probably the best treatment is washing out the stomach with a one-half per cent. solution of potassium permanganate repeatedly and leaving about half a pint of the solution in the stomach. In the absence of the stomach pump, three grains of copper sulphate may be given every five minutes until free emesis, and after the stomach has been thoroughly emptied a dose of four grains of potassium permanganate should be given.

Formerly workers in match factories were frequently attacked with a peculiar form of chronic phosphorus poisoning of which the most characteristic symptom was a necrosis of the jaw, whence the popular name of "phossy jaw." Since the introduction of red phosphorus this condition has become much less common.

Phosphorus should never be exhibited in substance, but the official pill is an eligible preparation. The *elixir* (*Elixir Phosphori,* N. F.) is probably the most eligible of the liquid preparations, but the *oil* (*Oleum Phosphoratum,* N. F. and Br.) is very efficient. Great caution is necessary in the exhibition of phosphorus, and its effects should be closely watched.

Dose, of phosphorus, from 1-100th to 1-80th of a grain (0.0006–0.0008 Gm.). Much larger doses than these have been given, but have in various cases produced unpleasant symptoms.

PHYSOSTIGMINÆ SALICYLAS. U. S.

PHYSOSTIGMINE SALICYLATE Physostig. Salicyl.
[Eserine Salicylate]

"The salicylate [$C_{15}H_{21}O_2N_3.C_7H_6O_3$] of an alkaloid obtained from the dried ripe seeds of *Physostigma venenosum* Balfour (Fam. *Leguminosæ*)." *U. S.*

Eserinum Salicylicum, *Fr. Cod.;* Salicylate d'Esérine, *Fr.;* Physostigminum salicylicum, *P. G.;* Physostigminsalicylat, Eserinsalicylat, *G.*

The seeds of the *Physostigma venenosum* Balfour (Fam. *Leguminosæ*) were formerly official but were dropped at the 10th revision of the U. S.

Physostigma venenosum is a perennial woody climbing plant indigenous to West Africa, frequenting especially the banks of streams, into which it often drops its fruit when ripe, and it is said that the people of Calabar derive their supply principally from the borders of the streams down which the fruits are carried. The rhizome is spreading, with numerous rootlets, often having attached to them small succulent tubers. The leaves are pinnately-compound, stipulate, each possessing 3 ovate, acuminate leaflets. The flowers are in axillary, multiflorous, pendulous racemes. The corolla is papilionaceous, of a pale pink color with a purplish tinge. The legume when ripe is about seven inches long, and contains two or three reniform or oblong seeds. It ripens at all seasons, but is most abundant during the rainy season from June to September. The seeds are the part used. The plant has been introduced into India and Brazil, and is said to flourish in the latter country. The market supplies are obtained from the regions surrounding the mouth of the Niger and the lower portion of the Calabar River, the chief port of export being Lagos (*Ap. Ztg.*, xxvi, p. 568; xxvii, p. 137). The commercial supply to the United States comes through London. For additional data on the botanical description, history, etc., of *Physostigma venenosum,* see papers by J. U. Lloyd in *West. Drug.*, 1897, 249 and G. Sharp in *Pharm. J.*, 1916, 619.

The seeds (*Physostigma* U. S. IX, *Calabar Bean; Chopnut; Ordeal Bean of Calabar; Esere Nut; Faba Calabarica; Fève du Calabar,* Fr.; *Kalabarbohne,* G.; *Eseve,* Sp.) were officially described as follows: "Oblong or ellipsoidal, somewhat compressed reniform, from 15 to 30 mm. in length and from 10 to 15 mm. in thickness; externally reddish or chocolate brown, smooth, somewhat wrinkled near the brownish-black groove, the latter being about 2 mm. in width and extending almost the entire length of the convex edge and in which are found frequently the remains of the white membranous funiculus, the margins of the seed-coat on both sides of the groove somewhat elevated, of a yellowish-red or brownish-red color and somewhat thickened; embryos large, white, with short hypocotyl and two concavo-convex cotyledons; taste at first starchy, afterwards acrid. The powder is grayish-white, starch grains numerous, from 0.005 to 0.15 mm. in diameter, ellipsoidal or somewhat reniform, and usually with a distinct cleft and frequently with radiating or irregular fissures; fragments of seed-coat with very thick, reddish-brown cells, being either palisade-like or very irregular and resembling stone cells, but the walls are not lignified; an occasional fragment with tracheæ showing reticulate thickenings. Physostigma yields not more than 3 per cent. of ash." *U. S. IX.*

The following assay process was official: "Introduce 15 Gm. of Physostigma in No. 60 powder, into a flask of about 250 mils capacity, and add 150 mils of ether. Stopper the flask, shake it well and allow it to stand ten minutes, then add 10 mils of an aqueous solution of sodium bicarbonate (1 in 20) and shake the mixture vigorously at intervals during four hours. Now add 15 mils of distilled water, again shake the flask well, and, when the drug has settled, decant 100 mils of the ether solution, representing 10 Gm. of Physostigma. Filter the solution through a pledget of purified cotton into a beaker and rinse the graduate and cotton with ether. Add 20 mils of tenth-normal sulphuric acid V.S. and evaporate off the ether, stirring during the evaporation with a rubber-tipped glass rod. After the resinous and fatty matter has agglutinated, pour off the acid solution through a wetted filter into a separator. Redissolve the residue in the beaker in about 15 mils of ether, add 2 mils of tenth-normal sulphuric acid V.S., evaporate off the ether with continued stirring as before and pour the acid solution on the filter. Repeat this operation until all the alkaloid is extracted and then wash the filter with distilled water until it is free from alkaloids. Collect the solution and washings in a separator, add sufficient sodium bicarbonate to make the solution decidedly alkaline to litmus and completely extract the alkaloids by shaking it out repeatedly with ether. Wash the combined ether solutions with 10 mils of distilled water, separate the water completely, and filter the ether solution, washing the container and filter with ether. Evaporate the ether solution to dryness, dissolve the alkaloids from the residue, add exactly 5 mils of tenth-normal sulphuric acid V.S. and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., using cochineal T.S. as indicator.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 27.52 milligrammes of the alkaloids of Physostigma." *U. S. IX.*

Calabar beans are occasionally substituted by a number of more or less similar seeds of African plants. Hartwich (*S. W. P.*, 1905, p. 441) calls attention to a false physostigma found in the Hamburg drug market which is derived from *Pentaclethra macrophylla* Benth., a leguminous tree indigenous to tropical Africa. The seeds are dark reddish-brown, from 5 to 7 cm. long, about 5 cm. broad and about 1 cm. thick. They are flattened-oval or roundish-triangular. Other substitutes have included the seeds of *Entada scandens* Benth. which are round, flat, brown and shining, about 5 cm. in width and the seeds of *Mucuna urens* De Candolle which are flattened and discoid and about 5 cm. in width.

The seeds of *Physostigma cylindrospermum* Holmes have occurred as an occasional adulterant of calabar beans. These are subcylindrical, up to 4 cm. long and possess a shorter raphe than the genuine article.

In 1864 Jobst and Hesse isolated an alkaloid to which they gave the name of *physostigmine.* The following year Vée and Leven obtained an alkaloid which they called *eserine,* from the African name for the drug. This latter was subsequently shown to be identical with physostigmine. Polonovski (*B. Soc. Chem.,* 1915, xvii; 1923, xxxiii) maintains that this does not occur naturally in the bean but is a reduction product of an alkaloid which he names *geneserine,* $C_{15}H_{21}O_3N_3$. Besides the principal alkaloid, the following other bases have been described: *Calabarine* (now usually known as *eseridine*) discovered by Harnack and Witkowski in 1876. The formula $C_{15}H_{23}O_3N_3$ has been given to it by Eber (*Ph. Ztg.,* 1888, p. 611), which differs from that of physostigmine, it will be seen, by H_2O only, and it is stated that the one can be changed into the other by the action of dilute acids. Salway (*Tr. Chem. Soc.,* 1911, xcix) was unable to confirm its presence. *Eseramine,* $C_{16}H_{25}O_3N_4$, was discovered by Ehrenberg in 1893 (*Verhand. d. Gesellsch. Deutsche Natur. u. Aertzte.,* 1893, ii, p. 102).

Still another alkaloid, announced by Salway (*Tr. Chem. Soc.,* 1911, xcix), is *physovenine,* $C_{14}H_{18}O_3N_2$. It is a powerful myotic like eserine. He believed it to be an intermediate product in the decomposition of eserine by alkalies, which results in the formation of a new base called *eseroline,* $C_{13}H_{18}ON_2$. Another decomposition product of eserine is produced by an excess of ammonia and is called *eserine blue,* $C_{17}H_{23}O_2N_3$.

Isophysostigmine, discovered by Ogiu in 1904, is isomeric with physostigmine and according to its discoverer, similar but more active in its physiological effects.

Basic physostigmine occurs: "In colorless or pinkish crystals, slightly soluble in water, but readily soluble in alcohol and in diluted acids. The aqueous solution has an alkaline reaction, when warmed with or when shaken with dilute solution of potash becomes red, and when evaporated to dryness over a water bath leaves a bluish residue, the acidified solution of which is beautifully dichroic, being blue and red." *Br.,* 1885.

A peculiarity of the alkaloid is that an aqueous solution of it, or of one of its salts, exposed to the air in the presence of potassium or sodium hydroxides, or lime, becomes red, owing to the absorption of oxygen. The coloring matter, sometimes called *rubreserine,* is taken up by chloroform. The color is not permanent, but gradually changes to yellow, green, or blue. This test will detect less than the hundred-thousandth part of the alkaloid. The same property is possessed by the alcoholic extract of the bean. This is the cause of the color changes taking place in solutions dispensed in ordinary glass bottles. The change may be retarded by previously rinsing out the bottle with diluted hydrochloric acid, and subsequently with distilled water, or it may be entirely prevented by coating the inner surface of the dispensing vial with paraffin.

The U. S. recognizes the salicylate in preference to the sulphate of the alkaloid which is in the Br. on account of its greater stability. Its advantage is that it is not deliquescent.

Description and Physical Properties.—"Colorless or faintly yellow, shining, odorless, crystals. It acquires a red tint when long exposed to light and air. *Caution—Physostigmine salicylate is extremely poisonous.*

"One Gm. of Physostigmine Salicylate is soluble in 75 cc. of water, 16 cc. of alcohol, 6 cc. of chloroform, and in 250 cc. of ether, at 25° C. One Gm. is soluble in 16 cc. of water at 80° C., and in 5 cc. of boiling alcohol.

"A cold-saturated aqueous solution of Physostigmine Salicylate is neutral, or only faintly acid to litmus paper. Upon standing, the solution usually acquires a pink color. Evaporate on a water bath about 0.005 Gm. of Physostigmine Salicylate with a few drops of ammonia T.S.: a blue residue is produced which, when dissolved in alcohol, yields a red, fluorescent solution upon the addition of an excess of acetic acid. On adding a few drops of sodium hydroxide T.S. to 5 cc. of a cold-saturated aqueous solution of the salt, a pink color rapidly develops. Ferric chloride T.S. produces a deep violet color in an aqueous solution of Physostigmine Salicylate.

"The ash from 0.1 Gm. is negligible. A solution of 0.1 Gm. of Physostigmine Salicylate in 2 cc. of sulphuric acid does not become darker than yellow within five minutes (*readily carbonizable substances*). Precipitate the salicylic acid from 10 cc. of a cold-saturated aqueous solution of the salt with a slight excess of diluted hydrochloric acid, and filter: the filtrate is not rendered turbid at once by the addition of 5 drops of barium chloride T.S. (*sulphate*).

"Preserve in small, well-closed containers, protected from light." *U. S.*

Uses.—Physostigma was introduced to the medical profession in 1840 by a missionary, Dr. Daniell, who had been laboring in Western Africa. Among the negroes of the Calabar coast this bean was used, under the name of *esere* as an ordeal, and, when given by their head men, usually proves fatal to the accused, unless free vomiting occurs. A draught containing 19 seeds pounded and infused in water is said to have killed a man in an hour. In the experiments of Fraser, it was found that the integuments of the seeds, as well as the shell, are distinctly purgative. It is probable that in the fresh bean they are also emetic, and that the priests or chiefs who administer the ordeal take advantage of this in regulating the effects of the poison to suit their own purposes; sometimes, however, even the pure alkaloid causes vomiting. (Gubler.)

The physiological actions of physostigmine divide themselves into three groups: depression of the central nervous system, increased irritability of the autonomic nerves, and stimulation of unstriped muscles. The depression of the central nervous system is most noticeably manifested in the diminution of reflex activities from depression of the spinal cord. After toxic doses the drug also depresses the respiratory center. Its effects upon the autonomic nerves are antagonistic to those of atropine (see *Atropina*). Among the most important of these actions are the slowing of the pulse by stimulation of the vagus, and the contraction of the pupil by stimulation of the oculomotor nerve. In large doses it also increases secretion, although it is not employed practically for this purpose. Although in sufficient dose physostigmine causes a rise in blood pressure by its stimulating action upon the cardiac and vascular muscles, the only therapeutically important action upon muscle tissue is on the intestinal tract. According to the studies of Magnus (*A. G. P.*, 1905, cviii, p. 1), it increases both the tone and the extent of contraction of the intestinal muscles.

Physostigmine is used in medicine chiefly to meet one of three indications. To contract the pupil in *glaucoma* and other diseases of the eye, it may be directly instilled into the diseased organ in strengths of from one-fourth to one-half of one per cent. As a stimulant to peristalsis it is useful in *chronic constipation, phantom tumor,* post-operative *intestinal atony, flatulent colic* and other conditions of deficient activity of the alimentary muscles. Edmunds (*J. P. Ex. T.*, 1923, xx, p. 405) concludes from his experimental studies that the occasional clinical failure of physostigmine to stimulate the intestinal muscles can be explained because of its action in increasing the output of epinephrin in the body, whose effects upon the intestines are antagonistic. Martin and Weiss (*J. A. M. A.*, 1925, lxxxiv, 1407) have used physostigmine with striking effects in post-operative flatulence. They believe that the reason it has so frequently failed in the hands of others is on account of insufficient dosage; they recommend from 1/20 to 1/16 grain (3 to 4 milligm.) be injected intramuscularly. These doses cause, besides the expulsion of gas, usually perspiration with increase of the pulse rate and frequently a rise in blood pressure. In many cases there was vomiting as well as belching. The drug was not successful in toxic type of case. As a sedative to the spinal cord it has been used in *tetanus* and *strychnine poisoning,* but clinical experience has shown that it is of much less value than chloral or the bromides. It has been recommended by Kaufmann (*W. K. W.*, 1912, p. 1080), by Lian and Welt (*B. Hop. Par.*, 1921, xlv, 559) and others in the treatment of *tachycardia* (*W. K. W.*, 1912, p. 1080).

Poisoning.—Of seventy children poisoned in Liverpool by eating Calabar beans which had been thrown upon a waste heap, vomiting occurred, or was produced by emetics, in all except one, in whom four kernels caused death. The nausea and vomiting came on in about half an hour, the nervous symptoms in less than an hour.

There are generally diminution of reflexes, coarse muscular tremors which may be sufficiently violent to suggest convulsions, contraction of the pupil, and progressive diminution of motor power. In the fatal cases death is generally due to paralytic asphyxia.

In the treatment of physostigma poisoning the stomach should be thoroughly washed out either with an emetic or the stomach pump, and tannic acid or compound solution of iodine given as a chemical antidote. Atropine, which is a partial physiological antagonist, should be given in doses of about one-fiftieth of a grain (0.0013 Gm.), and strychnine and other stimulants employed as indicated.

The *extract of the seeds* (*Extractum Physostigmatis,* U. S. IX) was given in doses of from one-sixth to one-half of a grain and the *tincture* (*Tinctura Physostigmatis,* U. S. IX) in doses of from ten to thirty minims (0.6–2.0 cc.).

Dose, of physostigmine salicylate, one-sixtieth to one twenty-fourth of a grain (0.0011–0.0025 Gm.).

PHYSOSTIGMINÆ SULPHAS. Br.

PHYSOSTIGMINE SULPHATE [Eserine Sulphate]

"Physostigmine Sulphate, $(C_{15}H_{21}N_3O_2)_2$-H_2SO_4, is the sulphate of an alkaloid, physostigmine, obtained from the seeds of Physostigma venenosum, *Balfour.*" *Br.*

Sulfate d'Esérine, *Fr.;* Physostigminum sulfuricum, *P. G.;* Physostigminsulfat, *G.;* Sulfatu de eserina, *Sp.*

This salt is preferred by the Br. to the salicylate on account of its greater solubility, but on exposure to the air it soon assumes an extractive consistence which renders it difficult to dispense; the salicylate is free from this objection.

Petit and Polonovski conducted experiments with the view of discovering salts of eserine which would be stable and non-hygroscopic; they made *eserine benzoate, eserine meta-cresotate, eserine citrate,* and *eserine tartrate.* Processes will be found in *J. P. C.*, 1894, 55.

Properties.—It is officially described as "minute white crystals, becoming yellowish on exposure to air and light; very deliquescent. Readily soluble in *water,* soluble in *alcohol* (90 per cent.). Aqueous solution neutral to *litmus;* yields the *reaction* characteristic of sulphates; yields with dilute *solution of sodium hydroxide* a white precipitate turning pink and forming a red solution with excess of the reagent; when mixed with *solution of ammonia* and evaporated to dryness on a water-bath it leaves a bluish residue, the solution of which in very dilute acids is dichroic, being red by reflected and blue by transmitted light. A minute fragment dissolved in a few drops of *fuming nitric* *acid* forms a yellow liquid, which, on warming on a water-bath, turns orange, then blood-red, and on evaporation to dryness leaves a green residue; this residue turns violet-blue on exposure to the fumes of *nitric acid,* and when moistened with the acid gives gradually a blood-red color, which changes to greenish-yellow on the addition of *water.* A dilute aqueous solution applied to the eye causes contraction of the pupil. No appreciable ash." *Br.*

Physostigmine sulphite has been patented and it is stated that it is more stable than either the salicylate or sulphate.

The medicinal properties, uses, and dose of physostigmine sulphate are the same as those of *Physostigminæ Salicylas.*

Dose, from one-sixtieth to one twenty-fourth of a grain (0.0011–0.0025 Gm.).

Off. Prep.—Lamellæ Physostigminæ, *Br.*

PHYTOLACCA. N. F.

PHYTOLACCA Phytolac. [Poke Root]

"Phytolacca is the dried root of *Phytolacca americana* Linné (Fam. *Phytolaccaceæ*). Phytolacca contains not more than 5 per cent. of its stem bases or more than 2 per cent. of other foreign organic matter." *N. F.*

Poke Root; Phytolaccæ Radix; Phytolacca Root; Racine de Phytolaque, *Fr.;* Kermesbeerenwurzel, *G.*

Phytolacca decandra L. is an indigenous plant, with a large, branching, perennial root, often 20 to 25 cm. in diameter, which is fleshy, fibrous, whitish within, and covered with a thin brownish cork. The stems, which are annual, frequently grow to the height of 6 to 15 dm., and divide into numerous spreading branches, which are green when young, but becoming purple especially in the upper portions after the berries have ripened. The leaves are alternate, short petiolate, ovate-oblong, entire, acute and glabrous. The flowers are small, greenish-white and in long racemes. The raceme of flowers becomes a cluster of dark purple, almost black, shining compound berries flattened above and below, and divided into ten loculi, each containing one seed.

Poke is abundant in all parts of the United States, flourishing in soil containing lime salts, along fences, by the borders of woods, in newly cleared fields, and especially in the muck thrown up from the ditches or swamps. It also grows spontaneously in northern Africa and southern Europe, where, however, it is supposed to have been introduced from America. Its flowers begin to appear in July, and the fruit ripens in autumn. The magnitude of the poke weed, its large rich leaves, and its beautiful clusters of purple berries, often mingled upon the same branch with the green unripe fruit and the flowers still in bloom, render it one of the most striking of our native plants. The young shoots are much used as food early in the spring, boiled in the manner of asparagus. The leaves, berries, and root are used in medicine, but the latter is the most active. It should be dug up late in November, cut into thin transverse slices, and dried with a moderate heat. As its virtues are diminished by keeping, a new supply should be procured every year. The berries should be collected when perfectly ripe, and the leaves about the middle of the summer, when the foot-stalks begin to redden.

Commercial quantities of poke root have been gathered for the market chiefly in Indiana, North Carolina and Virginia.

The berries (*Phytolaccæ Fructus,* U. S., 1890, *Phytolaccæ Baccæ, U. S.,* 1880, *Poke Berry*) contain a succulent pulp, and yield upon pressure a large quantity of fine purplish, red juice. They have a sweet, nauseous, slightly acrid taste, with little odor.

Description and Physical Properties.—"*Unground Phytolacca.*—Cylindrical, or somewhat tapering, sparingly branched, from 3 to 7 cm. in thickness, mostly in transverse or longitudinal slices; externally yellowish brown, finely longitudinally or spirally wrinkled and thickly annulate with lighter colored low ridges; fracture fibrous, characterized by alternating layers of fibrovascular tissue and parenchyma, the layers of the latter being much retracted. Odor slight; taste sweetish, afterwards highly acrid.

"*Powdered Phytolacca.*—Brownish yellow, sternutatory; starch grains simple or compound the individual grains mostly up to 0.025 mm., occasionally up to 0.035 mm. in diameter; calcium oxalate in raphides from 0.015 to 0.050 mm. in length; numerous fragments composed of parenchyma or of tracheæ with scalariform markings or bordered pores and long fibres; fragments of cork tissue." *N. F.*

Constituents.—We have no knowledge of the nature of the active principle of poke root. W. A. Partee (*A. J. P.,* 1888, p. 123) made a proximate examination of poke root and found crystals deposited from a solution of an alcoholic extract in absolute alcohol; he also discovered traces of tannin, glucose, and indications which pointed to the presence of a glucosidal principle. Frankforter and Ranaley (*A. J. P.,* 1897, 281) have again analyzed the root with care. They find nearly 10 per cent. of a non-reducing sugar, free acid, identified as formic acid, but no certain proof of either alkaloid or glucoside. The very bitter resin amounted to 1 per cent.; *phytolaccine,* an alkaloid, has been said to exist in minute quantities in the root. It contains a large amount (5.56 per cent.) of potassium (Frankforter, *A. J. P.,* 1897, p. 134). Claussen (*Pharmacist,* 1879) prepared from the seeds a neutral principle in silky lustrous crystals, insoluble in water, soluble in alcohol, ether, and chloroform, which he named *phytolaccin.* A. Tereil (*C. R. A. S.,* 1880, xci, 856) obtained from the berries an acid (*phytolaccic acid*) as an uncrystallizable yellowish-brown mass of gummy consistency. It was soluble in water and alcohol, slightly soluble in ether, of acid reaction, and gelatinizing with hydrochloric and sulphuric acids. W. F. Wagner (*A. J. P.,* 1887, p. 69) found tannin in the berries, but not in the root.

Uses.—Phytolacca is emetic, purgative and somewhat narcotic. Its properties were known to the American Indians before the arrival of the white man. As an emetic it is very slow in its operation, frequently not beginning to cause vomiting in less than one or two hours after it has been taken, and then continuing to act for a long time upon both the stomach and the bowels. The vomiting produced by it is said not to be attended with much pain or spasm, but narcotic effects have been observed by some physicians, such as drowsiness, vertigo, and dimness of vision. In overdoses it produces excessive vomiting and purging, attended with great prostration of strength, and sometimes with convulsions, and has, in several instances, proven fatal. According to Robert Bartholow, phytolacca causes in the lower animals convulsions and death from paralysis of respiration.

It is not fit for use as an emetic, but has been employed as an alterative in *chronic rheumatism, granular conjunctivitis,* and even in *cancer.* Locally it has been used in the form of ointment (a drachm to the ounce) in the treatment of *psora, tinea capitis, sycosis,* and *favus.* It occasions at first a sense of smarting and heat in the parts to which it is applied. It has been recommended, both internally and as a gargle, in various forms of *sore-throat.*

Dose, emetic, ten to twenty grains (0.6–1.2 Gm.), alterative, one to five grains (0.06–0.3 Gm.).

Off. Prep.—Fluidextractum Phytolaccæ, *N. F.*

PICRORHIZA. Br.

PICRORHIZA

"Picrorhiza is the dried rhizome of Picrorhiza Kurroa, *Royle.*" *Br.*

Kutki, Katki, Kuru, Kuruwa, Kaur, Karru, Kutaki, Kalikutki, or Black Kutki, Katukurogani, Kurroa.

Picrorhiza Kurroa Royle (*P. Kurrooa* Benth.), more properly known as *P. Lindleyana* (Wall. Wettst.), is a low, hairy perennial herb (Fam. *Scrophulariaceæ*), indigenous to the Alpine Himalayas. The rhizome has long been used in India and has been frequently spoken of by European and Mahometan writers as *black hellebore,* but is essentially different.

Properties.—Picrorhiza occurs "in cylindrical pieces two to five centimetres long, and four to eight millimetres thick, sometimes terminating in a stem or scaly leaf-bud; brittle. Cork greyish-brown, wrinkled, with transverse leaf scars and small buds. Fracture short. In transverse section internally dark and porous, with a thin, greyish cork and narrow ring of tangentially elongated wood-bundles. No odor; taste very bitter." *Br.*

Picrorhiza resembles externally the rhizome of *Gentiana Kurroo* Royle (Fam. *Gentianaceæ*), the latter, however, is uniformly brown internally, whereas the rhizome of Picrorhiza is darker or black, whence its name kali or black kutki.

From this rhizome H. Warden has separated a glucoside, *picrorhizin,* which is freely soluble in water and alcohol and appears to be the bitter principle of the drug; also a red-brown, resinous, tasteless body, *picrorhizetin,* and, perhaps, cathartic acid (*Pharmacog. Indica,* vol. 3).

Uses.—The natives of India attribute active antiperiodic power to picrorhiza, which appears to be a powerful bitter tonic with slight laxative action.

Dose, as a tonic, five to twenty grains (0.3–1.3 Gm.); as an antiperiodic, from forty to fifty grains (2.6–3.2 Gm.).

Off. Prep.—Extractum Picrorhizæ Liquidum, *Br.;* Tinctura Picrorhizæ, *Br.*

PILOCARPINÆ HYDROCHLORIDUM. U. S.

PILOCARPINE HYDROCHLORIDE Pilocarpin. Hydrochl.

"The hydrochloride [$C_{11}H_{16}O_2N_2.HCl$] of an alkaloid obtained from the dried leaflets of *Pilocarpus Jaborandi* Holmes, or of *Pilocarpus microphyllus* Stapf (Fam. *Rutaceæ*)." *U. S.*

Pilocarpinæ Hydrochloras, *U. S.* 1890; Chlorhydras Pilocarpinæ; Pilocarpine Hydrochlorate; Pilocarpine Chloride; Pilocarpinum Chlorhydricum, *Fr. Cod.;* Pilocarpinum Hydrochloricum, *P. G.*

Under the titles *Pilocarpus* (U. S. IX) or *Jaborandi Folia* (Br. 1898) the dried leaflets of various species of *Pilocarpus* have been official; at the present neither the Br. nor U. S. recognizes the crude drug although they do salts of the alkaloid. The terms *jaborandi* or *jamguarandi* are still commonly applied in commerce to these leaves although in South America they are used to designate various pungent, sudorific plants, some of which have no botanical relation at all with pilocarpus. What is called jaborandi in this country in South America is known as *Arruda do Mato* or as *Arruda brava* or, rarely, as *Jamguarandi* or *Jaurandi.*

The genus *Pilocarpus* consists of woody shrubs belonging to the *Rutaceæ* and inhabiting tropical and subtropical America, including Cuba, Guadeloupe, Martinique, and probably other islands. For elaborate botanical and histological studies of the commercial species of Pilocarpus, see the articles by A. Duvall, *B. Sc. Pharm.,* iii, pp. 41 and 98; Geiger, *Ber. d. D. Phar. Ges.,* 1897, p. 356; Hartwich, *Apoth. Zeit.,* 1900; Holmes, *P. J.,* 1903, p. 713; and 1904, p. 54; Schneider, *Jour. of Pharmacology* (N. Y. C. P.), 1897, No. 6; Tunman, *S. W. P.,* xlvii, p. 177.

P. Jaborandi Holmes (*P. officinalis* Pohl) yields the commercial variety known as Pernambuco Jaborandi. It inhabits the northern and northeastern part of Brazil. Its leaves are two or three jugate and are especially separated from those of the *P. pennatifolius* by the fact that all of the leaflets except the terminal one have their bases cordate, while the bases of all the leaflets of *P. pennatifolius* are attenuate. This commercial variety is practically no longer obtainable, only occasional lots being imported.

P. pennatifolius Lemaire (*P. simplex* Baillon), which yields Paraguay jaborandi, inhabits the southern portion of Brazil and Paraguay, whence its leaves were formerly largely exported through Buenos Ayres and Rio de Janeiro; at present they seem to have almost disappeared from commerce. The leaflets are grayish-green in color, oval, elliptical, obtuse, attenuate at the summit, which is feebly emarginate, and also attenuate at their base but not petiolated.

P. selloanus Engler appears to be a variety of *P. pennatifolius* Lemaire, from which it differs almost solely in the length of its flower stalk, which is six times as long as the flower bud, while that of *P. pennatifolius* is but three to four times as long as the bud. *P. selloanus* seems to be the more southern plant of the two, and is especially abundant in Paraguay. It has been imported from Rio de Janeiro.

P. microphyllus Stapf, which yields Maranham jaborandi, grows in the northeastern part of Brazil, whence the leaves, much mixed with the débris of the petioles, of the twigs and of the fruit, are sent to Liverpool and Hamburg. These leaves are alternate, imparipinnate having from one to five pairs of leaflets, or are often apparently simple owing to the failure of the lateral leaflets to develop. The leaflets are opposite, slightly pubescent, their petioles being marked by a deep longitudinal furrow. They vary very much in form, the base usually being attenuate and feebly cordate or unequal.

P. spicatus A. Saint-Hilaire (*P. parviflorus* Martius et Nees) inhabits the southern and northern portions of Brazil and can be recognized at once by its having simple leaves which are from 3 to 11 cm. long and from 1 to 4 cm. broad, and are tender or coriaceous and more or less pubescent and dotted. They are brownish-green above, paler beneath, and attached by a short twisted petiole. They appeared in commerce in 1895 under the name of *Arocati Jaborandi*. *P. subcoriaceus* Engler is probably a variety of this species. *P. racemosus* Vahl, a native of Martinique, Cuba, Guadeloupe and probably other of the West Indian Islands, appeared first in commerce in 1903 as a new variety of jaborandi under the name of *Guadeloupe jaborandi*. The leaves are proportionately broader than those of *Pernambuco jaborandi*, more obovate in outline, of a purer green color, and are trifoliate or apparently simple. Considerable diversity of result has been obtained by chemists in the examination of the Guadeloupe jaborandi. See Rocher (*A. J. P.*, 1900) and Cownley (*P. J.*, 1903, lxxii).

Other species, while never official, have appeared in commerce. These include: *P. trachylophus* Holmes whose leaflets are smaller than those of the *P. jaborandi*, and are oblong, elliptical, obtuse, and emarginate at the summit with cordate bases, symmetrically and shortly petiolate. The plant grows in northeastern Brazil, especially in the provinces of Ceará and Maranhoa, and the leaves, although they contain so little of the alkaloid (about 0.2 per cent.) as to be of small value, have been sent into commerce in considerable quantities. Their color upon the upper surface is dark olive green, below yellowish-green. The under surface is covered with short hairs.

The most common adulterant appears to be in lots of *P. microphyllus*, which often contain leaves of the leguminous plant, *Tunatea decipiens* (Holmes), O. Kze. (*Swartzia decipiens* Holmes). In general appearance the two leaves resemble one another, both being imparipinnate and having the leaflets about the same size and shape, but in *P. microphyllus* the leaflets are opposite and the petioles are only slightly pubescent, while in the *Tunatea* the leaflets are alternate, and the petioles very pubescent. Then again, the absence of secreting hairs, the deep green of the upper and lighter green of the lower surface of the leguminous leaf serve easily to distinguish it from the true drug.

The U. S. IX recognized the *P. jaborandi* and *P. microphyllus* which it described as follows: "*Pernambuco jaborandi.*—Leaflets when entire, oval, oblong, or elliptical from 4 to 10.5 cm. in length and from 2 to 4 cm. in breadth and with short, stout petiolules; summits more or less rounded or acute and emarginate; bases rounded or acute and mostly unequal; margins entire and narrowly revolute; very smooth, shiny, coriaceous and glandular-punctate; upper surfaces grayish to brownish-green, midribs mostly depressed, under surfaces yellowish- or greenish-brown and slightly pubescent on the prominent midvein; peculiarly aromatic when crushed; taste bitterish, becoming somewhat pungent and having a sialagogue effect.

"*Maranham Jaborandi.*—Leaflets rhomboidally oval to obovate or elliptical, from 1.5 to 5 cm. in length and from 1 to 3 cm. in breadth, the lateral ones nearly sessile, the terminal ones on margined petiolules, from 0.5 to 1.5 cm. in length; of a nearly uniform grayish or yellowish-green color, rather thin but otherwise resembling Pernambuco Jaborandi.

"Under the microscope, transverse sections of Pilocarpus show the upper epidermal cells with a yellowish layer of cutin from 0.005 to 0.01 mm. in thickness; palisade cells, 1 to 3 rows deep, being filled with chloroplastids; among the palisade cells occur large, nearly circular, oil-secretion reservoirs from 0.08 to 0.15 mm. in diameter; the dorsal pneumatic layer, from 10 to 20 rows in depth, the cells occasionally containing rosette aggregates of calcium oxalate from 0.01 to 0.025 mm. in diameter; distributed in the center of the leaf, are the collateral fibro-vascular bundles each surrounded by a more or less interrupted circle of several rows of thick-walled, slightly lignified bast-fibers; tracheæ associated with strongly lignified wood-fibers;

among the cells of the lower epidermis occur numerous stomata. On surface view the stomata are broadly elliptical, from 0.025 to 0.04 mm. in length, being uniformly smaller in Maranham Jaborandi. Upon both surfaces of Pernambuco Jaborandi occur a number of non-glandular, one-celled hairs, more or less bent or curved, from 0.08 to 0.5 mm. in length, thick-walled and with numerous, slight, centrifugal projections. The powder is dark green or greenish-brown; epidermal cells on surface view 5- or 6-sided; stomata broadly elliptical, from 0.02 to 0.04 mm. in length, usually with four neighboring cells; fragments of fibro-vascular bundles showing tracheæ with simple or bordered pores or spiral thickenings, associated with thick-walled and strongly lignified wood-fibres; bast-fibers few, walls thick and only slightly lignified, calcium oxalate in rosette aggregates, from 0.01 to 0.025 mm. in diameter; fragments of laminæ showing large, oil-secretion reservoirs and usually containing one or more globules of oil; non glandular hairs having thick walls, usually more or less broken, are occasionally found.

"Pilocarpus yields not more than 7 per cent. of ash." *U. S. IX.*

Assay.—"Introduce 15 Gm. of Pilocarpus in No. 60 powder into a 250 mil flask, add 150 mils of chloroform and proceed as directed under *Belladonnæ Radix*, page 222, fifth line of the assay, beginning with the word 'Stopper,' and decreasing the amount of water to be added after maceration to 5 mils. The 100 mils of chloroform solution must be drawn off from the bottom of the flask, and dissolve the alkaloids from the residue in 8 mils of tenth-normal sulphuric acid V.S.

"Each mil of tenth-normal sulphuric acid V.S. corresponds to 20.8 milligrammes of the alkaloids of Pilocarpus." *U. S. IX.*

Constituents.—An alkaloid was isolated in 1875 from jaborandi almost simultaneously by A. W. Gerrard and M. Hardy. To this the name of *pilocarpine* was given. A second base, *jaborine,* was reported by Harnak and Meyer (*Ann. Chem.,* 1880, 67); but Jowett (*Tr. Chem. Soc.,* 1900, 474, 851; 1901, 581, 1331) asserts this to be a mixture. In 1885 Harnak and Meyer (*Chem. Centr.,* 1885, 628) discovered still another alkaloid, *pilocarpidine,* which was confirmed by Jowett, although it cannot be found in the jaborandi of present day commerce. In 1897 still another alkaloid was isolated by Petit and Polonovski (*J. P. C.,* v, 370; vi, 8) from *Pilocarpus microphyllus,* which they also called *pilocarpidine,* under the impression that it was identical with that reported previously by Harnak and Meyer. This has been called *β-pilocarpine* by Brühl, and *isopilocarpine* by Jowett. Still another alkaloid called *pilosine* has been reported by Pyman. Petit and Polonovski later reported *ϕ-pilocarpine* and *ϕ-jaborine* in the leaves of *Pilocarpus spicatus.* He also obtained a volatile oil, tannic acid, a peculiar volatile acid, and potassium chloride.

Isopilocarpine (*betapilocarpine*) seems to be a stereo-isomer of pilocarpine. It is a colorless viscid oil-like liquid, forming crystalline salts, with an optical rotation of + 42.8. On oxidation by potassium permanganate it yields *pilopic acid,* $C_7H_{10}O_4$ and *homopilopic acid,* $C_8H_{12}O_4$.

Pilocarpidine, $C_{10}H_{14}O_2N_2$, is also liquid and forms crystalline salts. It is miscible with water and has an optical rotation of +81.3. Pilosine, $C_{16}H_{18}O_3N_2$, forms colorless crystals melting at 187°. It is sparingly soluble in water, ether or benzene, more soluble in boiling water or alcohol. *ϕ-pilocarpine* and *Φ-jaborine* are both amorphous, optically inactive bases.

An essential oil of sp. gr. 0.875, and boiling between 180° and 290° C., has been obtained by Schimmel & Co., Leipsic. (*B. Chem. G.,* April, 1888.) The portions going over above 260° C. solidified on cooling, and yielded a hydrocarbon, which fuses at 27° to 28° C. As it decolorizes notable amounts of bromine when in solution in petroleum benzin, it probably belongs to the olefine series. The yield of oil in pilocarpus is about 0.4 per cent. In a later report (Oct., 1893) they give dipentene as a probable constituent of the lower boiling portions of the oil. The total amount of essential oil varies, according to the freshness of the plant, from 0.2 to 1.1 per cent.

The alkaloid pilocarpine may be obtained from pilocarpus by the following process: The leaves are exhausted with 80 per cent. alcohol containing 8 grammes of hydrochloric acid in a liter, the tincture is distilled and evaporated to the consistence of a liquid extract, and this is mixed with a small quantity of water, and filtered. The filtrate is treated with a slight excess of ammonium, and then with a large quantity of chloroform. The chloroform solution is agitated with water, to which hydrochloric acid is added, drop by drop, in sufficient quantity to neutralize the alkaloid, the hydrochloride of which is obtained in long needles on evaporating the aqueous solution, while foreign principles remain dissolved in the chloroform. By dissolving the crystals in water, treating the solution with ammonia and chloroform, and evaporating the latter solution, pilocarpine is obtained as a soft viscous mass, which is only slightly soluble in water, but is freely soluble in alcohol, ether, and chloroform.

Kingzett originally assigned pilocarpine the formula $C_{23}H_{34}O_4N_4 + 4H_2O$. Harnack and Meyer, on the other hand, give it as $C_{11}H_{16}O_2N_2$. The latter has been generally accepted, and is recognized by the U. S. Pharmacopœia. When heated pilocarpine is changed into an isomeric compound, *isopilocarpine,* which also occurs naturally in the crude drug, see under *Pilocarpus.* Pilocarpine dissolves in soda solution with partial decomposition. Structurally, it is regarded as the lactone of *pilocarpic acid,*

$C_{11}H_8O_3N_2$ (see Petit and Polonovski, *J. P. C.*, 1897, v; *Bull. Soc. Chim.*, 1922, xxxi). For further studies in its structure see Pyman (*Tr. Chem. Soc.*, 1922, cxxi, 2616).

The nitrate has probably been used most frequently, and it and the hydrochloride are now official. Gerrard tested the solubilities of several of the salts as follows. The nitrate is soluble in water, sparingly in cold but freely in boiling alcohol; it is insoluble in chloroform, benzene, carbon disulphide, and ether. The *phosphate* is soluble in water, sparingly in cold, more freely in boiling, alcohol, from which on cooling it crystallizes in lustrous tables; it is insoluble in ether, chloroform, benzene, and carbon disulphide. The *hydrochloride* is freely soluble in water, alcohol and chloroform; insoluble in ether, benzene, and carbon disulphide. The *acetate* is soluble in water, alcohol, chloroform, benzene, and ether; insoluble in carbon disulphide. The *hydrobromide* is soluble in water, alcohol, and chloroform; insoluble in ether and carbon disulphide.

Description and Physical Properties.—Pilocarpine Hydrochloride occurs as "colorless, odorles, translucent crystals. It is hygroscopic. One Gm. of Pilocarpine Hydrochloride is soluble in 0.3 cc. of water, 3 cc. of alcohol, and in 366 cc. chloroform, at 25° C. One Gm. is soluble in 1.5 cc. of alcohol at 60° C. It is insoluble in ether.

"When dried to constant weight at 100° C., Pilocarpine Hydrochloride melts between 195° and 198° C. Its aqueous solution (1 in 20) is slightly acid to litmus paper. Dissolve 0.01 to 0.02 Gm. of Pilocarpine Hydrochloride in 2 cc. of distilled water in a test tube, add 2 cc. of a faintly acid hydrogen dioxide T.S., and cover the mixture with about 1 cc. of benzene. Add 3 or 4 drops of a solution of potassium dichromate (1 in 300) and shake the mixture gently: the benzene layer acquires a violet color, while the aqueous layer remains yellow (*distinction from other alkaloids*). (If more than 0.02 Gm. of the salt is used, the benzene turns blue and the reaction is no longer characteristic.) Silver nitrate T.S. produces, in an aqueous solution of the salt, a white precipitate, insoluble in nitric acid.

"The ash from 0.1 Gm. is negligible. A solution of 0.1 Gm. of Pilocarpine Hydrochloride in 2 cc. of sulphuric acid is colorless or at most only faintly yellow (*readily carbonizable substances*). The addition of ammonia T.S. or of potassium dichromate T.S. to 10 cc. of an aqueous solution of the salt (1 in 100) produces no turbidity (*various foreign alkaloids*).

"Preserve in well-closed containers, protected from light." *U. S.*

Uses.—The physiological effects of the various bases of pilocarpus have been studied by Harnak (*A. E. P. P.*, 1886, xx) and by Marshall (*J. Phys.*, 1904, xxxi). Jaborine appears to have an atropine-like effect, antagonistic to pilocarpine, and pilocarpic acid to be inert; the others resemble this alkaloid but are less active. The whole drug may be used for the same purposes as pilocarpine but is very little used except occasionally as a local remedy to stimulate the growth of hair for which, however, it is probably of no value.

Pilocarpine is the physiological antagonist of atropine, exciting those nerve endings which are paralyzed by that alkaloid. Thus it causes contraction of the pupil by stimulating the peripheral ends of the oculomotor nerve, increased flow of saliva by acting on the chorda tympani, slowing of the pulse through vagal stimulation (for some unknown reason the pulse rate is often increased in human beings), free sweating, and increased peristalsis of the intestines. The effects upon secretion are especially pronounced, the quantity of sweat brought out by a single dose of the alkaloid has been estimated at from 9 to 15 ounces. Ewing has shown that in the case of the salivary glands at least (*J. P. Ex. T.*, 1911, iii, p. 1) the increase is not merely in the watery constituents, but represents a true excitation of glandular activity because the solid matters and specific ferment of the secretion are also augmented. Usually there is more or less compensatory corollation between the degree of action on the various glandular structures, that is, if the sweat is greatly increased the effects upon the salivary glands, for instance, will be comparatively slight. There has been considerable difference of opinion among clinicians as to whether pilocarpine has any effect upon the kidney, and if so, what is the nature of this action, but the studies of Baco and Plumier (*J. de P. P.*, 1908, x, p. 32) have shown that the changes in the urinary output are secondary to the effects on the circulation; thus if the drug causes a fall of blood pressure the quantity of urine is diminished, but if there is no change in the circulation the kidney activity is unaffected. It is probable that in human beings the loss of water through the skin will also affect the quantity of urine.

Pilocarpine is used in medicine chiefly as a sudorific, either for the purpose of evacuating *dropsies* or aiding in the elimination of toxic substances, as in *uremia, gout, chronic rheumatism* and similar complaints. It should always, if possible, be used in conjunction with some form of external heat so as to determine the blood towards the skin. If used incautiously it may give rise to a very dangerous pulmonary edema. The mechanism of this is three-fold, an increase in the bronchial secretions, a reduction of the force of the circulation, and a spasm of the bronchial muscles. If the action of the drug has been directed towards the skin by other diaphoretic measures and the dose has not been unduly large, the likelihood of this accident is extremely remote. Its occurrence is the signal for the immediate exhibition of atropine. We believe that the doses sometimes employed are much larger than necessary. If properly used more than one-eighth of a grain hypodermically is very rarely needed. Pilocarpine has also been recommended by Reid (*J. A. M. A.*, 1911, lvi, p. 1739) in the treatment of *pruritus.* It is believed by some to have an effect upon the growth of the hair and is used both internally and topically in the treatment of *baldness.* Robinson (*J. A. M. A.*, 1914, lxiii, p. 63) reports favorable results in the treatment of *hypertension.* It is also asserted to be of value in *catarrhal jaundice.* As a local remedy it is employed by ophthalmologists as a myotic in strengths of one-half to one per cent.

When an overdose of jaborandi, or its principal alkaloid, has been taken, the symptoms begin with flushing of the face and neck, soon followed by free sweating and salivation, both of which may be extremely profuse. Frequently there is nausea and sometimes vomiting, the pulse is usually somewhat more rapid than normal, the pupils contracted, and often there is diarrhea. In patients with circulatory disturbances, pulmonary edema may occur, and prove rapidly fatal. The antagonism between pilocarpine and atropine is about as complete as between any two drugs, and the most certain treatment for cases of poisoning by jaborandi, after evacuating the stomach, is the prompt administration of a full dose of atropine, or some substance containing it.

Dose, of pilocarpine hydrochloride, one-twentieth to one-sixth of a grain (0.003–0.01 Gm.).

PILOCARPINÆ NITRAS. U. S., Br.

PILOCARPINE NITRATE Pilocarpin. Nit.

"The nitrate [$C_{11}H_{16}O_2N_2.HNO_3$] of an alkaloid obtained from the dried leaflets of *Pilocarpus Jaborandi* Holmes, or of *Pilocarpus microphyllus* Stapf (Fam. *Rutaceæ*)." *U. S.* "Pilocarpine Nitrate, $C_{11}H_{16}N_2O_2.HNO_3$, is the nitrate of an alkaloid, pilocarpine, obtained from the leaves of Pilocarpus microphyllus, *Stapf,* and other species of Pilocarpus." *Br.*

Pilocarpinum Nitricum, *Fr. Cod.;* Nitrate de Pilocarpine, *Fr.*

Preparation.—This salt may be made by adding pure pilocarpine to diluted nitric acid, carefully evaporating the solution, and purifying the crystals by solution in alcohol and recrystallizing.

Description and Physical Properties.—"Shining, colorless crystals. It is stable in the air. One Gm. of Pilocarpine Nitrate is soluble in 4 cc. of water and in 75 cc. of alcohol, at 25° C. One Gm. is soluble in 21 cc. of alcohol at 60° C. It is insoluble in chloroform and in ether.

"Pilocarpine Nitrate melts between 170° and 173° C. Its aqueous solution (1 in 20) is slightly acid to litmus paper. Dissolve from 0.01 to 0.02 Gm. of Pilocarpine Nitrate in 2 cc. of distilled water in a test tube, add 2 cc. of a faintly acid hydrogen dioxide T.S., and cover the mixture with about 1 cc. of benzene. Add 3 or 4 drops of a solution of potassium dichromate (1 in 300) and shake the mixture gently: the benzene layer acquires a violet color, while the aqueous layer remains yellow (*distinction from other alkaloids*). (If more than 0.02 Gm. of the salt is used, the benzene turns blue and the reaction is no longer characteristic.) Mix an aqueous solution of the salt with an equal volume of ferrous sulphate T.S., and superimpose the mixture upon 5 cc. of sulphuric acid, contained in a test tube: the line of contact becomes brown.

"The ash from 0.1 Gm. is negligible. A solution of 0.1 Gm. of Pilocarpine Nitrate in 2 cc. of sulphuric acid is colorless or at most only faintly yellow (*readily carbonizable substances*). The addition of a few drops of silver nitrate T.S. to 5 cc. of an aqueous solution of the salt (1 in 50), acidulated with nitric acid, does not at once produce an opalescence (*chloride*). The addition of ammonia T.S. or of potassium dichromate T.S. to 10 cc. of an aqueous solution of Pilocarpine Nitrate (1 in 100) produces no turbidity (*various foreign alkaloids*).

"Preserve in well-closed containers, protected from light." *U. S.*

"A white crystalline powder. Soluble in 8 parts of *water.* Melting point about 176° C. Yields with *sulphuric acid* a colorless solution slowly becoming green on the addition of *potassium bichromate.* When a solution of 0.01 gramme in 5 millilitres of *water* is mixed with 2 drops of *diluted sulphuric acid* and then with 1 millilitre of *solution of hydrogen peroxide,* 1 millilitre of *benzene,* and 1 drop of *solution of potassium chromate,* and the mixture well shaken and allowed to separate, the benzene is colored bluish-violet. No appreciable ash." *Br.*

The medicinal properties and dose are the same as those of *Pilocarpinæ Hydrochloridum.*

Dose, from one-twentieth to one-sixth of a grain (0.003–0.01 Gm.).

Off. Prep.—Elixir Tongæ et Salicylatum, *N. F.*

PILULÆ.

PILLS

Pilules, *Fr.;* Pillen, *G.;* Pillole, *It.;* Pildoras, *Sp.*

These are globular masses of a size convenient for swallowing. They are well adapted for the administration of medicines which are unpleasant to the taste or smell, or insoluble in water, and which do not require to be given in large doses. Deliquescent substances should not be made into pills, and those which are efflorescent should be previously deprived of their water of crystallization. Care should be taken not to combine materials the mutual reaction of which may result in a change of physical conditions.

Some substances have a consistence which enables them to be made immediately into pills. Such are the softer extracts and certain gum-resins, and the addition of a little water to the former, and of a few drops of alcohol to the latter, will give them the requisite softness and plasticity, if previously wanting. Substances which are very soft, or in the liquid state, are formed into a pill mass by incorporation with dry and inert powders, such as althea, glycyrrhiza or starch. A mixture of syrup and mucilage of acacia is an excellent excipient for certain kinds of pills. Honey has also been highly recommended. Confection of rose and glucose are among the favored excipients when the pills are to be kept long. For the same purpose of keeping the pills soft, the addition of a small portion of some fixed oil or deliquescent salt has been recommended, but glycerin is still better. Glycerin incorporated with one-twenty-fifth of its weight of powdered tragacanth is said to cause pills to remain soluble for almost any length of time. Glycerite of tragacanth is an excellent excipient. It has been objected that pills made with glycerin could not be handsomely gilded or silvered, the luster of the metal disappearing. This is true, however, only of very recent pills, or of those in which an excess of glycerin has been used. Many substances require only water as an excipient to form a mass. Care should always be taken that the excipient or the absorbent is not incompatible with the therapeutic constituents of the pill. For a list of excipients for pills see J. Cohn (*Ph. Ztg.*, 1900, 221); also G. Grugge (*A. Ph. A. Year Book*, 1914, p. 81).

The materials should be accurately mixed together, and beaten in a mortar until formed into a perfectly uniform and plastic mass. This should be of such a consistence that the pills may preserve their form, without being so hard as to resist the solvent power of the gastric fluids. The mass is made into pills by rolling it with a spatula, or with a flat, smooth piece of hard wood, into a cylinder of precisely the same thickness throughout, and of a length corresponding to the number of pills required. It is then divided as equally as possible by the hand, or, more accurately, by a machine. (See Remington's *Practice of Pharmacy*, 5th edition, p. 1217.) The pills receive a spherical form by being rolled between the fingers or by the use of one of the pill rolling machines. In order to prevent the adhesion of pills to one another, or to the sides of the vessel in which they may be placed, it is customary to agitate them with some dry powder, called a consperging powder (pulvis) which gives them an external coating, that serves also to disguise their taste. For this purpose, rice flour, lycopodium, glycyrrhiza or starch may be used. It is the custom in some sections of the United States, particularly on the Pacific coast, to give the pill a coating of gold or silver leaf. This is done by agitating the pills, prepared without dusting powder, and with their surface still damp, or coated with a very small quantity of mucilage, with gold or silver leaf, in an ordinary round pill box or in a hollow spherical wooden box made by turning two hemispheres out of hard wood, fitting each other, and provided with a short handle.

The gelatin coating of pills, originally proposed by Garot, was formerly done on the small scale by forms of apparatus devised particularly for extemporaneous use. Gelatin coating of pills is now done on the large scale only. For forms of apparatus formerly used see *U. S. D.*, 20th ed., pp. 859 and 860.

Gelatin coating on the larger scale is accomplished by the use of the vacuum apparatus of J. B. Russell (see Remington's *Practice of Pharmacy*), or by simply rotating the pills in contact with a solution of gelatin in large spherical vessels, such as are used for sugar coating.

The sugar coating of pills is now conducted upon a large scale by manufacturers, who send immense quantities both of popular and of official pills into the market thus protected. The process employed is similar to that of the confectioners in coating almonds. After having been thoroughly dried, the pills are put into a hemispherical tinned copper basin, which is suspended from the ceiling and moved quickly backward and forward with an eccentric motion, so as to cause a constant attrition among the pills. First a little very thick syrup, or syrup of gum, is introduced in order to give a thin coating to their surface, and afterwards very finely powdered and very dry white sugar is sifted or thrown over them, the motion being constantly maintained. The sugar is fixed by the moist surface of the pills, and the coating made compact and smooth by the attrition. The process is aided by a gentle heat, but the heat must be guarded, lest the pills be much softened, and thus lose their shape and even discolor the coating. Dexterous manipulation is necessary in order that the process may succeed thoroughly.

Blanchard covers pills with a solution of Tolu balsam in ether, but H. C. Baildon objects to this, that it takes too long to dry, and suggests as a substitute a solution of a drachm of the balsam in three drachms of chloroform, which dries sufficiently in twenty minutes. If old and solid Tolu balsam be selected, it will be less liable to the objection of drying slowly. This balsam is officially employed in coating the U. S. pills of ferrous iodide. A solution of mastic in ether has also been used for coating pills, and the white of egg has been recommended for the same purpose.

Pills are sometimes coated with substances which do not dissolve in the stomach, with the object of permitting the passage of the undissolved pill into the intestines; for this purpose keratin coating has been largely used. (See *Keratin*, Part II, and Remington's *Practice of Pharmacy*, seventh edition.) Salol has also been employed, by melting it in an enamelled pan at a temperature of about 50° C. and dropping in the pills, rotating until covered, and then transferring to a dry pan, still rotating (to prevent adhesion) until cold. An improved method of salol coating for pills intended for enteric use has been contributed by J. C. and B. L. DeG. Peacock (*Proc. P. Ph. A.*, 1915, p. 258). The particular points to be observed are the amount of salol to be used and the shape and size of the vessel used in melting the salol. W. G. Toplis (*Proc. P. Ph. A.*, 1915, p. 262) proposes stearic acid as an enteric coating for pills and gives details of the method to be followed in producing a satisfactory article.

Maske (*J. A. Ph. A.*, 1917, vi, 1059) has investigated the rapidity of disintegration of pills made with various masses, in artificial gastric juice. He finds that a soft mass, composed of equal parts of glycyrrhiza and manna disintegrated in 15 minutes; and one of kaolin and petrolatum had not, even although the mixture was agitated mechanically, at the end of eight hours. Under the latter conditions no "enteric pill" was found that had not lost its coating at the end of one and a half hours.

Pills which are to be kept long should be well dried, and put into bottles with loosely fitting stoppers to prevent mouldiness. Though the U. S. Pharmacopœia, in almost every instance, orders the mass to be divided into pills, yet it should be understood rather as indicating the number of pills to be made from a certain quantity of the mass, when particular directions are not given by the physician, than as requiring the division to be made immediately after the materials have been mixed. It will be found convenient by the apothecary to retain a portion of the mass undivided, especially when it is desirable to keep the pills soft. The British Pharmacopœia furnishes formulas for pill masses, using the title of "Pilula" instead of "Massa," the title of the class adopted by the U. S. Pharmacopœia; there is, in our opinion, a decided advantage in selecting a name for the class which is not likely to be confused with that used for the divided pills.

Pills containing silver nitrate, potassium permanganate or other strongly oxidizing substances, should be made by diluting with kaolin or talc and massing with petrolatum or mixtures of petrolatum and paraffin. All organic matter should be excluded.

Compressed pills (*Pilulæ comprimatæ*) or *tablets* (*Tabellæ, Tablettæ*) as they are usually called are made directly from the medicinal substance without the aid of an excipient. The drug, if not already in granular powder, is made so, and then forced into pill shape by means of a powerful press. For certain substances which are crystalline in structure, such as quinine bisulphate, potassium bromide, and potassium iodide, and which have some cohesiveness and yet are of easy solubility, the process is a good one. An apparatus was contrived by J. P. Remington for compressing pills for extemporaneous prescription work (see 16th ed., *U. S. D.*, and *Practice of Pharmacy*). It is made of cast steel; the base has two countersunk depressions with a short post in the center of each, and a lenticular depression is made in the upper surface of each post. A steel cylinder having a central aperture of the diameter of the post is placed in the depression, the proper quantity of powder is introduced, and the plunger, which has a corresponding lenticular depression on its lower surface, is placed on the powder and is struck a quick blow with a mallet; the powder is compressed, and the pill adheres to the cylinder; by removing the cylinder and holding it over a box and tapping the plunger again lightly, the pill is forced out and falls into a box.

Compressed tablets are now used to an enormous extent, being made by various manufacturers with machinery of ingenious construction; the ease with which they can be tested, and their permanent character (in most cases being just as valuable years after they were made as when fresh) have caused their extensive employment.

For a description of some of the more important forms of pill compressing machines with illustrations, see Remington's *Practice of Pharmacy,* seventh edition.

PILULÆ ALOES. U. S. (Br.)

PILLS OF ALOE Pil. Aloes.

Pilula Aloes, *Br.;* Aloes Pill; Pill of Barbados Aloes, Pill of Socotrine Aloes; Pilules d'Aloés et de Savon, Pilules Aloétiques Savoneuses, *Fr.;* Alœpillen, *G.*

"Aloe, in very fine powder, 13 Gm.; Soap, in very fine powder, 13 Gm.; Water, a sufficient quantity, to make 100 pills. Mix the powders intimately, then incorporate sufficient water to form a mass, and divide it into 100 pills." *U. S.*

"Aloes, in powder, 58 *grammes;* Hard Soap, in powder, 29 *grammes;* Oil of Caraway, 3 *millilitres;* Syrup of Glucose, 10 *grammes* or *a sufficient quantity.* Mix to form a mass." *Br.*

In the Br. Pharm., 1898, confection of rose was used as the excipient. It is now replaced by syrup of glucose.

The former British process for *Pill of Socotrine Aloes* was the same except that Socotrine was substituted for Barbados Aloes, and the volatile oil of nutmeg for oil of caraway.

The soap, in this formula, not only serves to impart a proper consistence to the aloes, but is thought to qualify its operation and diminish its liability to irritate the rectum. They are employed as a laxative in *habitual costiveness.*

Dose, one, two or three pills at bedtime. The British pill mass is of very nearly the same strength as that of the U. S. Pharmacopœia.

PILULA ALOES ET ASAFETIDÆ. Br.

PILL OF ALOES AND ASAFETIDA

Pilules d'Aloés et d'Asefétide, *Fr.;* Aloe und Asafœtida-Pillen, *G.*

"Aloes, in powder, 30 *grammes;* Asafetida, 30 *grammes;* Hard Soap, in powder, 30 *grammes;* Syrup of Glucose, 10 *grammes,* or *a* *sufficient quantity.* Mix to form a mass." *Br.*

A similar pill is recognized by the N. F. (see Part III).

Pills made from this mass are peculiarly adapted, by the stimulant and carminative properties of the asafetida, to cases of *costiveness* attended with flatulence and debility of the digestive organs.

Dose, from four to eight grains (0.25–0.5 Gm.) of the mass.

PILULA ALOES ET FERRI. Br.

PILL OF ALOES AND IRON

Pilulæ Italicæ Nigræ; Pilules d'Aloés et de Fer, *Fr.;* Pilulæ Aloeticæ ferratæ, *P. G.;* Eisenhaltige Aloepillen, Aloe und Eisenpillen, Italienische Pillen, *G.*

"Exsiccated Ferrous Sulphate, 10 *grammes;* Aloes, in powder, 20 *grammes;* Compound Powder of Cinnamon, 35 *grammes;* Syrup of Glucose, 35 *grammes,* or *a sufficient quantity.* Mix to form a mass." *Br.*

The N. F. recognizes a very similar mixture (see Part III).

This pill is essentially an old preparation of the Edinburgh Pharmacopœia. The Br. Pharm., 1898, improved this mass by substituting exsiccated ferrous sulphate for the crystallized salt formerly employed, and by the use of syrup of glucose instead of confection of rose. It is said that the laxative power of aloes is increased, and its tendency to irritate the rectum diminished, by combination with ferrous sulphate. This pill is especially adapted to *amenorrhea* with debility of the stomach and constipation.

Dose, of the Br. mass, from three to eight grains (0.2–0.5 Gm.).

PILULA ALOES ET MYRRHÆ. Br.

PILL OF ALOES AND MYRRH

Rufus's Pills; Pilule d'Aloés et de Myrrhe, Pilules de Rufus, *Fr.;* Rufussche Pillen, *G.*

"Aloes, in powder, 44 *grammes;* Myrrh, in powder, 22 *grammes;* Syrup of Glucose, 34 *grammes,* or *a sufficient quantity.* Mix to form a mass." *Br.*

A very similar combination is recognized by the N. F. (see Part III).

This composition is employed, as a warm stimulant cathartic, in *general debility* attended with *constipation,* and in *retention* or *suppression of the menses.*

Dose, of the Br. mass, from four to eight grains (0.26–0.5 Gm.).

PILULÆ ASAFŒTIDÆ. U. S.

PILLS OF ASAFETIDA Pil. Asafœt.

Pilules d'Asefétide, *Fr.;* Asafœtida-Pillen, *G.*

"Asafetida, 20 Gm.; Soap, in very fine powder, 6 Gm.; Water, a sufficient quantity, to make 100 pills. Intimately incorporate the solids, using sufficient water to form a mass, and divide it into 100 pills." *U. S.*

Each of these pills contains three grains (0.20 Gm.) of asafetida. They are a convenient form for administering asafetida, the unpleasant odor and taste of which render it very offensive in the liquid state.

Dose, one to three pills.

PILULA COLOCYNTHIDIS COMPOSITA. Br.

COMPOUND PILL OF COLOCYNTH

Cochia Pills; Pilules de Coloquinte composées, *Fr. Cod.;* Pilules cochées mineures, *Fr.;* Zusammengesetzte Koloquinten Pillen, *G.*

"Colocynth Pulp, in powder, 20 *grammes;* Aloes, in powder, 35 *grammes;* Scammony Resin, in powder, 35 *grammes;* Potassium Sulphate, in powder, 5 *grammes;* Oil of Cloves, 5 *millilitres;* Distilled Water, *a sufficient quantity.* Triturate the Oil of Cloves with the Potassium Sulphate; add the Colocynth Pulp; mix; add the Aloes and Scammony Resin; mix; add Distilled Water, and mix to form a mass." *Br.*

This is not, like the old London pills of the same name, merely another form of the compound extract of colocynth, though containing essentially the same materials—one great difference being that colocynth and aloes are used in substance in the pill, instead of in the state of extract. Potassium sulphate is used to promote the more complete division of the aloes and scammony. The preparation is actively cathartic.

Dose, from five to eight grains (0.32–0.5 Gm.).

Off. Prep.—Pilula Colocynthidis et Hyoscyami, *Br.*

PILULA COLOCYNTHIDIS ET HYOSCYAMI. Br.

PILL OF COLOCYNTH AND HYOSCYAMUS

Pilules de Coloquinte et d'Extrait de Jusquiame *Fr.;* Koloquinten-Bilsenkrautpillenmasse, *G.*

"Compound Pill of Colocynth, 50 *grammes;* Extract of Hyoscyamus, 25 *grammes;* Distilled Water, *a sufficient quantity.* Mix to form a mass." *Br.*

This was an official pill of the Edinburgh College. It is asserted that the compound pill and compound extract of colocynth are almost entirely deprived of their griping tendency by combination, as above, with extract of hyoscyamus, without losing any of their purgative power.

Dose, from five to eight grains (0.32–0.5 Gm.).

PILULÆ FERRI CARBONATIS. U. S. (Br.)

PILLS OF FERROUS CARBONATE Pil. Ferr Carb [Ferruginous Pills, Chalybeate Pills, Blaud's Pills]

"Each Pill contains not less than 0.06 Gm. of $FeCO_3$." *U. S.*

Pilula Ferri, *Br.;* Iron Pill; Pilules Ferrugineuses de Blaud, *Fr. Cod.;* Pilules Chalybées de Blaud, *Fr.;* Pilulæ Ferri carbonici Blaudii, *P. G.;* Blaudsche Pillen, *G.;* Pillole di carbonato ferroso, *It.;* Pildoras de Blaud, *Sp*

"Granulated Ferrous Sulphate, 16 Gm.; Potassium Carbonate, 8 Gm.; Sucrose, 4 Gm.; Tragacanth, in very fine powder, 1 Gm.; Althea, in very fine powder, 1 Gm.; Glycerin, Water, each, a sufficient quantity, to make 100 pills. Triturate the potassium carbonate in a mortar with a sufficient quantity (about 5 drops each) of glycerin and water, then add the ferrous sulphate and sucrose, previously triturated together to a uniform, fine powder, and mix the mass thoroughly until it assumes a greenish color. When the reaction is complete, incorporate the tragacanth and althea, and add more water, if necessary, to obtain a mass of pilular consistence. Divide into 100 pills.

"Preserve in tightly-closed containers." *U. S.*

"Exsiccated Ferrous Sulphate, in powder, 33 *grammes;* Exsiccated Sodium Carbonate, in powder, 21 *grammes;* Tragacanth, in powder, 2 *grammes;* Gum Acacia, in powder, 8 *grammes;* Glucose, 31 *grammes;* Distilled Water, 2 *millilitres.* Mix the Glucose, Distilled Water, and Exsiccated Ferrous Sulphate; add the Exsiccated Sodium Carbonate; mix and set aside for ten minutes, or until the reaction is complete; add the Tragacanth and Gum Acacia, and mix to form a mass. This Pill contains about 22.5 per cent. of ferrous carbonate." *Br.*

Assay.—"Dissolve three Pills in 15 cc. of diluted sulphuric acid, and dilute the solution with distilled water to about 100 cc. Immediately titrate with tenth-normal potassium dichromate, potassium ferricyanide T.S. being used as indicator. Each cc. of tenth-normal potassium dichromate corresponds to 0.01159 Gm. of $FeCO_3$." *U. S.*

These pills afford one of the best forms of exhibiting iron, in the treatment of *anemia,* being nearly free from astringency. As their peculiar advantages depend upon the presence of ferrous carbonate, which speedily changes into the ferric salt on exposure, it is proper that only so much of the mass should be prepared as may be wanted for immediate use. They are sometimes called *Griffith's pills.* They closely resemble *Blaud's ferruginous pills,* made originally in 1831, and celebrated in France as a remedy in *chlorosis,* prepared from equal weights of ferrous sulphate and potassium carbonate, made into a pilular mass. (See *P. J.,* 1894, 131.) The pills contain, as the result of double decomposition, ferrous carbonate and potassium sulphate. Van de Velde and Van Melckebeke prefer the sodium bicarbonate to the potassium salt. For a brief historical account of these pills, see a paper by John Humphrey in *P. J.,* 1903, 643.

Blaud's pills may become very harl upon standing, but if properly made, they undergo very little alteration. For an assay of a very old specimen, see *N. J. Ph. A.,* 1912, p. 73.

Dose, from two to six pills, to be taken three times a day; of the Br. mass, five to twenty grains (0.32–1.3 Gm.).

PILULÆ HYDRARGYRI CHLORIDI MITIS COMPOSITÆ. U. S.

COMPOUND PILLS OF MILD MERCUROUS CHLORIDE Pil. Hydrarg. Chlor. Mit. Co. [Pilulæ Catharticæ Compositæ U. S. P. IX]

Compound Cathartic Pills; Compound Calomel Pills; Antibilious Pills; Pilules cathartiques composées, *Fr.;* Abführpillen, *G.*

The new name of these pills although rather cumbersome is to be preferred as descriptive of their chief ingredient rather than their therapeutic property.

"Compound Extract of Colocynth, 80 Gm.; Mild Mercurous Chloride, 60 Gm.; Resin of Jalap, in fine powder, 20 Gm.; Gamboge, in very fine powder, 15 Gm.; Diluted Alcohol, a sufficient quantity, to make 1000 pills. Mix the powders intimately, then incorporate a sufficient quantity of diluted alcohol to form a mass, and divide it into 1000 pills." *U. S.*

This cathartic compound was first made official in the second edition of the U. S. Pharmacopœia. It was intended to combine smallness of bulk with efficiency and comparative mildness of purgative action and a peculiar tendency to the biliary organs. The object of smallness of bulk is accomplished by employing extracts and the more energetic cathartics; that of a peculiar tendency to the liver, by the use of calomel, and that of efficiency with mildness of operation, by the union of several powerful purgatives. It is a fact, abundantly proved by experience, that drastic cathartics become milder by combination, without losing any of their purgative power. It is highly important that these pills be prepared in exact compliance with the directions, and that the compound extract of colocynth and the resin of jalap used be of good quality.

Each pill weighs about 3 grains (0.194 Gm.), and contains 2.70 grains (0.175 Gm.) of active ingredients. A single pill will generally be found to operate as a mild laxative. In a full dose, the preparation acts vigorously on the bowels, producing bilious stools, generally without much pain or disorder of the stomach. It may be employed in most instances where a brisk cathartic is required, but is particularly applicable to the early stages of *bilious fevers,* and to all those derangements which depend on congestion of the portal circle. It should not be used in habitual constipation.

Dose, one to three pills.

PILULA HYDRARGYRI SUBCHLORIDI COMPOSITA. Br.

COMPOUND PILL OF MERCUROUS CHLORIDE [Compound Calomel Pill, Plummer's Pill]

Compound Pills of Antimony; Pilula Calomelanos Composita, *Br.* 1864; Compound Pill of Mercurous Chloride; Pilules alterantes composées, Pilules antidartreuses, Pilules de Plummer, *Fr.;* Plummersche Pillen, Zusammengesetzte Calomelpillen, *G.*

"Mercurous Chloride, 20 *grammes;* Sulphurated Antimony, 20 *grammes;* Guaiacum Resin, in powder, 40 *grammes;* Gum Acacia, in powder, 1 *gramme;* Tragacanth, in powder, 1 *gramme;* Syrup of Glucose, 10 *grammes,* or *a sufficient quantity.* Mix to form a mass." *Br.*

Compound pills of antimony were dropped in the U. S. P. VIII, but the National Formulary IV has introduced the compound pill of antimony of the U. S. P., 1890, without alteration (see *Pilulæ Antimonii Compositæ,* Part III). This pill is official in the British Pharmacopœia, 1914, castor oil, which was used as an excipient, being replaced by syrup of glucose. "Compound Calomel Pill" of the British Pharmacopœia should not be confounded with the compound calomel pill of the U. S. as the two possess very different therapeutic virtues.

According to Vogel a reaction takes place between the calomel and the sulphurated antimony, resulting in the production of antimony chloride and mercury sulphide. The preparation was originally introduced to the notice of the profession by Dr. Plummer, who found it useful as an alterative, and upon whose authority it was at one time much employed under the name of *Plummer's Pills.* The combination is used in the treatment of *chronic rheumatism* and of scaly and other *eruptive diseases of the skin,* especially when accompanied with a syphilitic taint.

Dose, four to eight grains (0.26–0.5 Gm.) or more, morning and evening.

PILULA IPECACUANHÆ CUM SCILLA. Br.

PILL OF IPECACUANHA WITH SQUILL

Pilules d'Ipécacuanha et de Scille, *Fr.;* Brechwurzel-Meerzwiebelpillen, *G.*

"Compound Powder of Ipecacuanha, 30 *grammes;* Squill, in powder, 10 *grammes;* Ammoniacum, in powder, 10 *grammes;* Syrup of Glucose, *a sufficient quantity.* Mix to form a mass. This Pill contains about 5 per cent. of Opium." *Br.*

This is an old-fashioned combination of expectorants, intended for *chronic bronchitis,* but scarcely in keeping with modern practice.

Dose, from five to ten grains (0.32–0.65 Gm.).

PILULA IPECACUANHÆ CUM URGINEA. Br.

PILL OF IPECACUANHA WITH URGINEA

"Compound Powder of Ipecacuanha, 30 *grammes;* Urginea, in powder, 10 *grammes;* Ammoniacum, in powder, 10 *grammes;* Syrup of Glucose, *a sufficient quantity.* Mix to form a mass. This Pill contains about 5 per cent. of Opium." *Br.*

This is the same as Pill of Ipecacuanha with Squill, except that Indian Squill or Urginea is used in place of the Mediterranean variety.

PILULÆ PHOSPHORI. U. S. (Br.)

PILLS OF PHOSPHORUS Pil. Phosphor.

Pilula Phosphori, *Br.;* Phosphorus Pill; Pilules au Phosphore, Pilules Phosphorées, *Fr.;* Phosphorpillen, *G.*

"Phosphorus, 0.06 Gm.; Althea, in very fine powder, 6.00 Gm.; Acacia, in very fine powder, 3.00 Gm.; Chloroform, Glycerin, Water, Tolu, Ether, each, a sufficient quantity, to make 100 pills. Dissolve the phosphorus in a test tube in 5 cc. of chloroform, with the aid of a very gentle heat, replacing from time to time any of the chloroform which may be lost by evaporation. Mix the althea and acacia in a mortar, next add the solution of phosphorus, then immediately afterwards a sufficient quantity (about 4 cc.) of a mixture of 2 volumes of glycerin and 1 volume of water, and quickly form a mass. Divide it into 100 pills. Dissolve 10 Gm. of tolu in 15 cc. of ether, shake the pills with a sufficient quantity of this solution until they are uniformly coated and put them on a plate to dry, occasionally rolling them about until the drying is completed.

"Preserve in a well-stoppered bottle." *U. S.*

"Phosphorus, 1 *gramme;* Oil of Theobroma, 40 *grammes;* Wool Fat, 11 *grammes;* Kaolin, 16 *grammes;* Sodium Sulphate, dried at 100° C., 32 *grammes;* Carbon Disulphide, 20 *millilitres.* Dissolve the Phosphorus and 20 *grammes* of the Oil of Theobroma in the Carbon Disulphide. Allow the solution to evaporate in a mortar until a pasty mass is obtained. To this add the remainder of the Oil of Theobroma together with the other ingredients, and mix to form a mass. This Pill contains 1 per cent. of Phosphorus. It is of one-half the strength of the corresponding preparation of the British Pharmacopœia, 1898. It should be freshly prepared." *Br.*

The problem of preventing the oxidation of the phosphorus is believed to be solved by dissolving it in an excess of warm chloroform; this is accomplished in a stoppered test-tube, for it has been shown that no oxidation takes place in the presence of chloroform vapor. It is necessary to form the mass quickly, so that the chloroform may not all evaporate and leave the phosphorus exposed to the action of the air. Chloroform is preferable to carbon disulphide, as recommended in the Br., for, although the latter is a better solvent, it is difficult to rid the mass of the disgusting odor.

The formula for this pill in the British Pharmacopœia, 1914, has been improved and simplified by replacing white wax and lard with oil of theobroma and wool fat, and its strength has been reduced to one-half of that of the Br., 1898.

Each official U. S. pill contains about 1-100th of a grain (0.0006 Gm.) of phosphorus.

Dose, of the U. S. pills, one pill three times a day; of the Br. mass, one grain (0.065 Gm.).

PILULA PLUMBI CUM OPIO. Br.

PILL OF LEAD WITH OPIUM

Pilules d'Acétate de Plomb et d'Opium, *Fr.;* Bleiacetat-Opiumpillenmasse, *G.*

"Lead Acetate, in powder, 80 *grammes;* Opium, in powder, 12 *grammes;* Syrup of Glucose, 8 *grammes,* or *a sufficient quantity.* Mix to form a mass. This Pill contains about 12 per cent. of Opium." *Br.*

This pill would be better left to extemporaneous prescription, the requisite proportion of opium to the lead acetate varying in different cases. A similar preparation is also official in the N. F. (see *Pilulæ Opii et Plumbi,* Part III).

Dose, two or three grains (0.13–0.20 Gm.) to begin with.

PILULA QUININÆ SULPHATIS. Br.

PILL OF QUININE SULPHATE

Pilule de Quinine Sulfate, *Fr.;* Chininpillenmasse, *G.;* Pildoras de sulfato quinico, *Sp.*

"Quinine Sulphate, 82 *grammes;* Tartaric Acid, in powder, 3 *grammes;* Glycerin, 12 *grammes;* Tragacanth, in powder, 3 *grammes.* Triturate the Quinine Sulphate with the Tartaric Acid; add the product to the previously mixed Glycerin and Tragacanth; mix to form a mass." *Br.*

The reason for introducing a quinine pill mass in the British Pharm. is doubtless to serve the convenience of dispensers and to save time; tartaric acid aids in solubility and in making the pills smaller, while glycerin keeps the mass from undue hardening.

Dose, two to eight grains (0.13–0.5 Gm.).

PILULA RHEI COMPOSITÆ. Br.

COMPOUND PILL OF RHUBARB Pil. Rhei Co.

Pilules de Rhubarbe composées, *Fr.;* Rhabarber und Aloepillen, *G.*

"Rhubarb, in powder, 25 *grammes;* Aloes, in powder, 20 *grammes;* Myrrh, in powder, 14 *grammes;* Hard Soap, in powder, 14 *grammes;* Oil of Peppermint, 2 *millilitres;* Syrup of Glucose, 25 *grammes,* or *a sufficient quantity.* Mix to form a mass." *Br.*

A similar pill is recognized by the N. F. (see Part III).

This is a tonic laxative, useful in *costiveness.* If made in quantity the pills should be kept in loosely stoppered bottles. The use of glycerin favors the formation of mouldiness through the attraction of moisture, and it was replaced in the formula of the Br. Ph., 1898, by syrup of glucose.

Dose, from five to eight grains (0.32–0.5 Gm.) of the mass, twice a day.

PILULA SAPONIS COMPOSITA. Br.

COMPOUND PILL OF SOAP

Pilulæ Opii, *U. S. VIII,* Pill of Opium; Pilules de Savon composées, *Fr.;* Seifenpillenmasse, *G.*

"Opium, in powder, 20 *grammes;* Hard Soap, in powder, 60 *grammes;* Syrup of Glucose, 20 *grammes,* or *a sufficient quantity.* Mix to form a mass. This Pill contains about 20 per cent. of Opium." *Br.*

This pill is practically identical with the opium pill of the U. S. VIII. There is no evident need of such a pill; it might much more wisely be left to extemporaneous prescription. The name was probably intended to conceal the nature of the preparation, but, in our opinion, it is a mistake to omit the only important ingredient from the title. One grain (0.065 Gm.) of opium is contained in five grains (0.32 Gm.) of the mass.

Dose, from two to five grains (0.13–0.32 Gm.).

PILULA SCILLÆ COMPOSITA. Br.

COMPOUND SQUILL PILL

Pilules de Scille composées, *Fr.;* Meerzwiebelpillenmasse, *G.*

"Squill, in powder, 25 *grammes;* Ginger, in powder, 20 *grammes;* Ammoniacum, in powder, 20 *grammes;* Hard Soap, in powder, 15 *grammes;* Syrup of Glucose, 20 *grammes,* or *a sufficient quantity.* Mix to form a mass." *Br.*

This is a stimulating expectorant compound, depending for its virtues chiefly on the squill, and applicable to the treatment of *chronic bronchitis.* The mass should be freshly made when wanted, as the squill which it contains is liable to be injured by keeping.

Dose, from four to eight grains (0.25–0.5 Gm.).

PILULA URGINEÆ COMPOSITA. Br.

COMPOUND URGINEA PILL

"Urginea, in powder, 25 *grammes;* Ginger, in powder, 20 *grammes;* Ammoniacum, in powder, 20 *grammes;* Hard Soap, in powder, 15 grammes; Syrup of Glucose, 20 *grammes,* or *a sufficient quantity.* Mix to form a mass." *Br.*

This pill is the same as the Compound Squill pill, except that the Indian Squill, Urginea, replaces the ordinary variety.

Dose, from four to eight grains (0.25–0.5 Gm.).

PIMENTA. N. F.

PIMENTA Piment. [Allspice]

"Pimenta is the dried nearly ripe fruit of *Pimenta officinalis* Lindley (Fam. *Myrtaceæ*). Pimenta contains not more than 3 per cent. of foreign organic matter and not more than 0.4 per cent. of acid insoluble ash." *N. F.*

Allspice; Clove Pepper; Pimento; Semen Amomi; Piper Jamaicense; Pimento; Allspice; Jamaica Pepper; Piment de la Jamaïque, Touteépice; Poivre de la Jamaïque, *Fr.;* Englisches Gewürz; Neugewürz; Nelkenpfeffer, *G.;* Pimenti, *It.;* Pimienta de la Jamaica, *Sp.*

Pimenta Pimenta (L.) Karsten (*P. officinalis* Lindley; *Myrtus Pimenta* L.; *Eugenia Pimenta* DC.) is an evergreen tree, 25 to 40 feet in height, with an erect trunk and round-topped crown. The leaves are entire, ovate-oblong and glandular-dotted beneath. The flowers are small, white and borne in racemose cymes. Each consists of a sub-globose calyx tube with a four-divided limb, four petals, numerous stamens and a two-celled inferior ovary. The fruit is a two-celled and two-seeded inferior berry, each cell containing a single plano-convex, reddish-brown seed.

This tree is a native of the West Indies and the adjoining coast of continental America. The earlier Spanish adventurers mistook the berries for a species of pepper which mistake is commemorated in the botanical name of the genus, "pimenta" (from the Spanish word for a pepper) and is also perpetuated in one of the common English names, "Jamaica pepper." It is cultivated in Central America and the surrounding countries, but the supply to the United States and Great Britain comes from Jamaica, where the tree is so abundant as to form in the mountainous districts whole forests, and to require no further cultivation than the clearing out of the underbrush. The berries are gathered after having attained their full size, but while yet green, and are carefully dried in the sun. When sufficiently dry, they are put into bags and casks for exportation. The fruits of four other species of the genus *Pimenta*, found in Venezuela, Guiana, and the West Indies, are employed in their native countries as spices.

Description and Physical Properties.—"*Unground Pimenta.*—Sub-globular, from 4 to 7 mm. in diameter, apex with four calyx teeth forming a minute ring; externally dark brown, somewhat rough and glandular-punctate; pericarp brittle, about 1 mm. in thickness; two-celled and two-seeded; dissepiments thin; seeds plano-convex, slightly reniform, externally reddish brown, smooth, somewhat wrinkled and shiny. Odor and taste, particularly of the pericarp, aromatic and distinctive.

"*Powdered Pimenta.*—Reddish brown or dark brown, shows irregular fragments and numerous starch grains, the latter being either simple or compound, the individual grains spherical, plano-convex or polygonal, from 0.003 to 0.015 mm. in diameter, occasionally up to 0.020 mm. in diameter, and frequently with a central circular marking or cleft; stone cells numerous, of tabular, pyriform or variable shape and with thick, porous, and strongly lignified walls, the lumina frequently filled with a yellowish or reddish brown amorphous substance, fragments with oil secretion reservoirs containing globules of a yellowish brown oil; parenchyma cells with reddish brown tannin masses. Stem fragments very few, and characterized by more or less curved, thick-walled, non-glandular hairs, rosettes of calcium oxalate, from 0.006 to 0.020 mm. in diameter, tracheid-like tissues of the wood and long narrow bast fibers. The yield of crude fiber does not exceed 25 per cent." *N. F.*

The odor of Pimenta berries is thought to resemble that of a mixture of cinnamon, cloves, and nutmeg. Hence the name of *allspice*, by which they are best known in this country. They impart their flavor to water, and all their virtues to alcohol. The infusion is of a brown color, and reddens litmus paper.

Pimenta yields from 3 to 4.5 per cent. of a volatile oil. (See *Oleum Pimentæ.*) Besides the volatile oil, pimenta contains over 8 per cent. of tannic acid, a soft green resin with a burning aromatic taste and other unimportant vegetable matters. The ash, according to the standards of the Association of Food and Dairy Departments, should not be more than 6 per cent. and not more than 0.5 per cent. insoluble in hydrochloric acid. According to Bonastre, the shell contains 10 per cent. of the volatile and 8 of the fixed oil, the seeds only 5 per cent. of the former, and 2.5 of the latter. Dragendorff, in 1871, announced the existence of an alkaloid in allspice. It is present in exceedingly small quantity, and has somewhat the odor of coniine.

Pimenta is sometimes adulterated by the larger and less aromatic berries of the Mexican allspice (*Eugenia Tabasco* G. Don). Powdered pimenta has been also adulterated with all sorts of substances as ground cocoanut shells, cereal starches, etc.

Uses.—Pimenta is an aromatic spice, used in medicine chiefly as an adjuvant to tonics and purgatives. It is particularly useful in cases attended with much *flatulence*. It is, however, much more largely employed as a condiment than as a medicine.

Aqua Pimentæ Br., 1898, was formerly official—it was a distilled water.

Dose, ten to forty grains (0.65–2.6 Gm.).

Off. Prep.—Tinctura Guaiaci Composita, *N. F.*

PINUS ALBA. N. F.

WHITE PINE BARK Pin. Alb.

"White Pine Bark is the dried inner bark of *Pinus Strobus* Linné (Fam. *Pinaceæ*). White Pine Bark contains not more than 2 per cent. of outer bark and not more than 2 per cent. of foreign organic matter." *N. F.*

Deal Pine; Weymouth Pine; Northern Pine.

The *Pinus Strobus* or *white pine* is a large handsome evergreen tree reaching a height of 150 feet, found throughout the whole eastern portion of the U. S. and lower Canada as far south as Georgia, being most abundant in New England and Canada. Its leaves are soft, bluish-green, 2 to 5 inches long and occur in fascicles of five. Its carpellate cones are slender, cylindric and elongated with oblong-obovate scales bearing winged reddish-brown seeds. Its wood, because of its light color, ease of working and freedom from resin is one of the most highly esteemed sorts of lumber. The part used in medicine is the dried inner bark which is officially described as follows:

Description and Physical Properties.—"*Unground White Pine Bark.*—In flat pieces of variable size and from 1 to 3 mm. in thickness; outer surface varying from a pale pinkish white when fresh, to a light or rather deep yellowish brown on keeping, occasionally with small patches of the gray-brown periderm adhering; more or less cottony, and often showing small scattered pits; inner surface either lighter or darker than the outer, finely striate; fracture short, irregular, transverse section showing an outer yellowish and an inner whitish band. Odor slight, terebinthinate; taste slightly mucilaginous, bitter, sweet and astringent.

"*Powdered White Pine Bark.*—Numerous rounded or oval, simple starch grains, up to 0.030 mm. in diameter, a very few slightly larger, some having a cleft or fissure through the center; few monoclinic prisms of calcium oxalate up to 0.025 mm. in length; resin in reddish brown, angular masses; thin-walled parenchyma cells, isodiametric or elongated, many containing starch grains; tracheids very few or absent." *N. F.*

Of the medicinal constituents of the pine bark we have no satisfactory knowledge. It contains a glucoside *coniferin*, $C_{16}H_{22}O_8.2H_2O$. This, when decomposed, yields *coniferyl alcohol* which can be oxidized to vanillin. It is not probable that this principle is of any remedial value although it is a commercial source for synthetic vanillin. The bark also contains upwards of 10 per cent. of tannin. Presumably the therapeutic value of the bark resides in the resin, which, however, as far as we know, has not been carefully investigated.

Uses.—White pine bark is used as an ingredient in cough syrups. As it is always employed in conjunction with other remedial agents, it is difficult to determine whether it does possess any real virtues. We are strongly persuaded, however, that the syrup of white pine with morphine, although—or rather because of the fact—it is outside the limit of the Harrison Antinarcotic Act, has much more potency for evil as a habit-forming drug than for benefit as a therapeutic agent.

Dose, from fifteen to forty-five grains (1–3 Gm.).

Off. Prep.—Syrupus Pini Albæ Compositus, *N. F.;* Syrupus Pini Albæ Compositus cum Morphina, *N. F.*

PIPER. N. F.

PEPPER [Black Pepper]

"Pepper is the dried, unripe fruit of *Piper nigrum* Linné (Fam. *Piperaceæ*). Pepper contains not more than 2 per cent. of stems or other foreign matter." *N. F.*

Piper Nigrum, *Br.* 1898; Common Pepper; Fructus Piperis Nigri; Poivre noir, *Fr.;* Schwarzer Pfeffer, *G.;* Pepenero, *It.;* Pimienti negra, *Sp.;* Fifil uswud, *Arab.;* Lada, *Malay;* Maricha, *Jav.;* Sahan, *Palembang.*

The pepper vine (*Piper nigrum*) is a perennial plant, with a round, smooth, woody, articulated stem, swelling near the joints, branched, and from eight to twelve feet or more in length. The leaves are entire, broad-ovate, acuminate, five- to nine-nerved, coriaceous, very smooth, of a dark green color, and attached by strong sheath-like petioles to the joints of the branches. The flowers are small, whitish, sessile, covering thickly a cylindrical pendulous spike, and succeeded by globular sessile drupes which are red when ripe.

The plant is a native of southern India and grows wild in Cochin-China and various parts of India. It is cultivated on the coast of Malabar, in the peninsula of Malacca, in Siam, Sumatra, Singapore, Johore, Borneo, the Philippines, Japan and many other places in the East; also to some extent in the West Indies. The chief commercial supplies now come from Singapore. The plant is propagated by cuttings, and is supported by props, or trees planted for the purpose, upon which it is trained. In three or four years from the period of planting, it begins to bear fruit. The plant sometimes begins to bear as early as the first year after planting, increases in its yield to the fifth or sixth year, when it produces eight or ten pounds, and begins to lose its productiveness about the fifteenth year. The fruits are gathered while green and dried in the sun or above fires, when they become black and wrinkled. The fire-dried fruits possess a smoky odor and taste and are the most esteemed. The greatest production is in Sumatra, and the ports of export are principally Singapore and Penang, the Malabar pepper coming from Tellicherry. In England, at least, it is customary to mix peppers of different origin in grinding, taking Malabar for weight, Penang for strength, and Sumatra for color. Owing to the widespread cultivation of pepper a large number of varieties exist; these receive their names from the place of their production or their ports of shipment, as Singapore, Acheen, Penang, Siam, Tellicherry, Trang, Lampong, etc. For a description of the most important of these varieties with the percentage of active constituents contained in each, see J. W. Gladhill, *A. J. P.*, Feb., 1904; Kraemer and Sindall, *A. J. P.*, 1908, p. 1; also Blyth, *Foods: Their Composition and Analysis.*

White pepper is the nearly ripe drupe, deprived of the outer part of its pericarp by maceration in water and subsequent friction, and afterwards dried in the sun. It occurs as yellowish more or less broken grains with a smooth shiny surface from which the epicarp or outer layer of the fruit has been removed. It is sold in the market either as a whole white pepper or as broken white pepper; the whole peppers are very likely to have some of the epicarp or hull remaining. The removed hull is sold separately under the name of "pepper hulls"; it forms a light to dark brown powder, with a very pungent odor and taste and contains large amounts of the oleoresin of pepper, but according to Gladhill, no piperine. The hulls are sometimes sold mixed with broken white pepper. This mixture contains more oleoresin and less piperine than does the pure pepper; the percentage of the two active constituents varying according to the percentage of drugs in the mixture. White pepper is much less pungent but more aromatic than black pepper.

Long Pepper is obtained from *Piper officinarum* Casimir DC., and *P. longum* L., the former species yielding the principal commercial supplies and being grown in Java, India, and the Philippines. The plants are distinguished in having their flowers in dense, short terminal, and nearly cylindrical spikes and their fruits, consisting of very small one-seeded drupes, embedded in a pulpy matter. The fruit is green when immature, and becomes red as it ripens. It is gathered in the former state, as it is then hotter than when perfectly ripe. The whole spike is taken from the plant, and dried in the sun. The fruit of the *P. officinarum* is cylindrical, 2 to 6 cm. long and 4 to 7 mm. in diameter, indented on its surface, of a dark-gray color, a weak aromatic odor, and a pungent fiery taste. The fruits of *P. longum* are shorter and thicker. Dulong found its chemical composition to be closely analogous to that of black pepper. *West African* or *Ashantee Pepper* is the fruit of *P. Clussii,* C. DC., which grows abundantly in tropical Africa. It does not come into Western commerce, although much used in Africa. The berry is described as resembling cubeb, but less rugose, and with a more slender pedicel and having the odor and taste of black pepper. Stenhouse found piperine in this variety of pepper.

Kissi Pepper is a fruit yielded by the *Piper Famechoni,* Heckel, of Upper Guinea. The berries, which grow in cylindrical clusters, are small, blackish-brown, ovoidal, with a cubeb-like pedicel at their base. Their powder is very aromatic, with an especially pleasant taste. They have been found by A. Barille to contain 4.5 per cent. of volatile oil and 3.7 per cent. of piperine. (*J. P. C.,* 1903, 106.)

Description and Physical Properties.—"*Unground Pepper.*—Nearly globular, from 3.5 to 6 mm. in diameter, epicarp very thin, easily separable from the sarcocarp; externally blackish brown or grayish black, coarsely reticulate; unilocular, 1-seeded; seed nearly white, hollow, adhering to the pericarp. Odor aromatic, slightly empyreumatic; taste aromatic and very pungent.

"*Powdered Pepper.*—The powder is a mixture of blackish brown fragments of the pericarp and nearly white fragments of the perisperm and embryo; starch grains spherical or somewhat angular, from 0.001 to 0.003 mm. in diameter, mostly in the polygonal cells of the perisperm; stone cells of the epicarp varying from nearly isodiametric or palisade-like to long tapering or somewhat irregular in shape, with thick porous walls and large lumina frequently containing a reddish brown pigment; stone cells of the endocarp unevenly thickened, the outer walls being usually rather thin, and the lumina usually filled with a reddish brown substance; oil cells with suberized walls and containing a yellowish oil, from which monoclinic prisms of piperine occasionally separate. Pepper yields not less than 6 per cent. of non-volatile extract, soluble in ether. It contains not less than 25 per cent. of starch." *N. F.*

For information on the pharmacognosy of pepper, see Winton and Moeller in the "*Microscopy of Vegetable Foods;*" Spaeth, *Ztchr. f. Unters. d. Nahr. u. Genussm.,* 1908, xv, p. 472; Kraemer and Sindall, *A. J. P.,* 1908, lxxx, p. 1; Collin in *Ann. des. Falsifications,* 1910, iii, p. 272; Wallis, *Chem. News,* cxi, 143.

Constituents.—Pepper contains three important ingredients, a volatile oil, a resin and piperine. The volatile oil is composed of terpenes, chiefly lævo-phellandrene. It is colorless or slightly yellow lævo-rotatory with a specific gravity of 0.880 and 0.905. It is not pungent but represents the characteristic aromatic flavor of the pepper.

The resin, sometimes called *chavicin,* is a soft greenish substance, extremely pungent but without odor. Its pungency is by many attributed to the presence of piperine. A mixture of the volatile oil and resin which was made by extracting with ether, was formerly official under the name of *Oleoresina Piperis.* The process for this was as follows:

"Pepper, in No. 40 powder, *five hundred grammes;* Ether, *a sufficient quantity.* Place the pepper in a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle for volatile liquids. Pack the powder firmly, and percolate slowly with ether, added in successive portions, until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water bath, and, having transferred the residue to a dish, set this aside in a warm place until the remaining ether has evaporated, and the deposition of piperine has ceased. Lastly, separate the Oleoresin from the piperine by straining through purified cotton. Keep the Oleoresin in a well-stoppered bottle." *U. S. IX.*

Piperine, $C_{17}O_{19}O_3N$, which may be regarded as the true active principle of black pepper was defined by the U. S. VIII as "a feebly basic substance [$CH_2O_2.C_6H_3.CH:CH.CH.:CH.CON.-C_5H_{10}$] obtained from Pepper and other plants of the *Piperaceæ.*" *U. S. VIII.*

Piperine is prepared by exhausting pepper with strong alcohol, recovering the solvent and treating the oleoresinous residue with sodium hydroxide solution to saponify the resins. The residue is taken up with boiling 95 per cent. alcohol, the solution filtered through animal charcoal and then allowed to crystallize.

The amount of piperine in the berries is from 4 to 10 per cent.

It was officially described as "colorless or pale yellowish, glistening, monoclinic crystals, odorless, permanent in the air, and containing no water of crystallization. When put into the mouth, it is at first tasteless, but on prolonged contact it develops a sharp, biting taste. It is optically inactive. Insoluble in water; soluble in 15 parts of alcohol, 36 parts of ether, and in 1.7 parts of chloroform at 25° C., soluble in 4.4 parts of alcohol at 60° C. It melts at 130° C. Upon ignition, it emits alkaline vapors, and is completely consumed. Its alcoholic solution is neutral to litmus paper. Sulphuric acid dissolves Piperine with the formation of a blood-red color, which disappears on dilution with water. On heating Piperine with alcoholic potassium hydroxide, it is converted into piperinic acid and piperidine, the latter recognizable by its alkaline, pepper-like odor, and the former by its melting point, 215° C. On adding a crystal of Piperine to sulphuric acid containing about half its volume of solution of formaldehyde, a permanently green liquid is formed. On adding a crystal of Piperine to sulphuric acid containing a fragment of potassium dichromate, it at once acquires a purple color, and, on stirring, dissolves, forming a reddish-brown solution, which becomes greenish on adding water to it. On adding a crystal of Piperine to sulphuric acid containing a trace of selenous acid, it turns brown, changing at once to violet, and dissolves, forming a brown solution changing to green. When heated with nitric acid, Piperine is colored at first orange, then red, and the acid acquires a yellow color, deepening to reddish as the crystals dissolve. On adding to this solution an excess of potassium hydroxide T.S., the color is at first yellow, but upon boiling, it becomes blood-red." *U. S. VIII.*

Piperine has such feebly basic properties that its salts are immediately decomposed by solution. By boiling with an alcoholic solution of potassium hydroxide, it is split up into a strongly basic substance, *piperidine,* and *piperic acid,* $C_{12}H_9O_3$. Piperidine, which probably occurs naturally in small quantities in pepper, is a volatile, liquid alkaloid with a boiling point of 106° C., soluble in either alcohol or water and forming crystalline salts. It is of great chemical interest as being a simple derivative of pyridine (See Part II), which seems to underlie the molecular structure of so many alkaloids. Piperidine is *hexahydropyridine,* $C_5H_{11}N$, and can be easily obtained from pyridine by the action of tin and hydrochloric acid, or when sodium acts upon the alcoholic solution. Conversely, piperidine can be changed into pyridine when sulphuric acid at 300° C. or gentle oxidizing agents act upon it. Coniine, it will be remembered (see *Conium*), has been shown synthetically to be a normal propyl-piperidine.

For a paper on commercial peppers, by J. W. Gladhill, see *A. J. P.*, 1904, 71.

Adulterations.—On account of its extensive use as a condiment pepper has been largely adulterated, especially when sold in the form of a powder. Chief of the adulterants are pepper-hulls, ground olive pits, wheat middlings, and roasted cereals. Among the other substances sometimes used have been ground beans or peas, corn starch, flaxseed, mustard hulls, and coffee hulls. The adulterated articles are usually fortified with the addition of Cayenne pepper. At the present time, by virtue of the National and State Food Laws, black pepper is seldom adulterated. Adulterations can be detected by the microscope with more or less ease (see *P. J.*, lxxi, 269; *P. J.*, June, 1890; *Bull. U. S. Dept. of Agriculture,* No. 13, Part II, pp. 183, 1887; *A. J. P.*, 1887, 146); but when pepper has been adulterated to the amount of 10 per cent. the discovery of the fraud is best made by determining the proportion of ash, of ether extract and of piperine present. The ash should never be above 6.5 per cent. for black and 3 per cent. for white pepper; the ether extract should be between 7.5 and 10 per cent. for black and 6 to 9 per cent. for white pepper, the U. S. standard being not less than 6 per cent. in which not less than 3.25 per cent. nitrogen shall be present. Piperine should be present in from 5.5 to 9 per cent. in good black pepper. The amount of oleoresin in any pepper can readily be determined by subtracting the weight of piperine from that of the mixture. Penang pepper is sometimes made to resemble the higher priced white peppers by coating the grains with an earthy matter (lime or clay). According to A. Mennechet, the fruits of *Myrsine africana* and of *Embelia Ribes* may sometimes be detected in the powder of pepper by extracting with ether and adding a little water, followed by a few drops of ammonia, when after shaking, a deep lilac-red color will appear in the aqueous layer. (*J. P. C.*, xiv, 587.)

Uses.—Black pepper is a warm carminative stimulant, capable of producing general arterial excitement, but acting with greater proportional energy on the part to which it is applied. From the time of Hippocrates it has been used as a condiment and in medicine. Its chief medicinal application is to excite the languid stomach and correct *flatulence.* In the early part of the 19th century piperine enjoyed a considerable popularity as a remedy for *malarial fever.* Although the evidence seems strong that it does really possess some antiperiodic powers, it is not comparable to the preparations of cinchona and has almost completely passed out of use except as an ingredient in Warburg's tincture and similar preparations. Some have attempted to explain its synergism with cinchona on the ground that its action on the stomach improves the absorption of quinine, but there is on the one hand no evidence that it does improve the absorption of quinine, and on the other hand considerable evidence that it possesses intrinsic anti-malarial powers (for evidence on this see Husemann, *Die Pflanzenstoffe,* 1882, p. 491).

The dose of the oleoresin of pepper is from one-fourth to one minim. Piperine as an antiperiodic was given in doses of five to eight grains (0.3–0.5 Gm.).

Dose, of pepper, five to twenty grains (0.32–1.3 Gm.).

PITUITARIUM. U. S.

PITUITARY Pituitar. [Hypophysis Sicca U. S. P. IX]

"Pituitary is the cleaned, dried, and powdered posterior lobe obtained from the pituitary body of domesticated animals which are used for food by man." *U. S.*

The *Hypophysis cerebri,* or *pituitary body,* is a small bean-shaped body found within the skull in the depression known as the *sella turcica* or pituitary fossa. Its longest diameter is in the transverse direction and it consists of two distinct portions enclosed together in a connective-tissue capsule. The smaller, or *posterior lobe,* is composed of nerve cells similar to the gray matter of the brain and continuous with the *infundibulum* which forms a portion of the floor of the third ventricle of the brain. The *anterior lobe,* which is much larger, is made up of glandular epithelium and contains here and there collections of colloid material homologous to that found in the thyroid body. In the human being the pituitary body measures about 12 mm. transversely, 7 mm. longitudinally and 5 mm. vertically, and weighs from five to twenty grains. In cattle the organ has a weight of two or three drachms (8–12 Gm.). When dried it loses approximately three-fourths of its weight.

Description and Physical Properties.—"A yellowish or grayish amorphous powder, having a characteristic odor. It is only partially soluble in water." *U. S.*

The anterior, or glandular, portion of the pituitary body has important relations with the metabolic processes. The condition known as gigantism or acromegaly, which is characterized by an increased growth of the bones, is generally attributed to overactivity of the pituitary gland; conversely, failure of this gland leads to retardation of growth. A lack of pituitary activity also leads to a peculiar form of corpulence, accompanied with loss of sexual characteristics, but it is not yet certain whether this form of hypopituitarism is due to disease of the anterior or posterior lobe. (See *Organotherapy,* Part II.)

When an extract of the posterior lobe is injected into the circulation of a normal animal it produces marked physiological effects which are more closely described below. This action is so analogous to other drug actions that it is impossible to escape the conviction that there is some principle or principles present in the posterior lobe which acts as a stimulant to unstriped muscle. What the nature of this principle is has not yet been determined. Abel demonstrated the presence of histamine in the hypophysis and at first was inclined to the opinion that this was the active principle, but in a later communication (*J. P. & Ex. T.,* 1920, xv, p. 347) expressed the conviction that the histamine was not the proper active principle but that it was a frequent contamination of commercial preparations. Dudley (*J. P. & Ex. T.,* 1919, xiv, 295) has separated, by means of a precipitation with colloidal ferric hydroxide, and subsequent extraction with butyl alcohol, crystalline residues which possessed all the physiological powers of the hypophysis extract, but not in a state of sufficient purity for analysis.

Because of our ignorance of the active principle of the hypophysis it is at present impossible to devise a process for chemical assay.

For description of the biological methods which have been suggested see under *Liquor Pituitarii.*

Uses.—In 1899 Schafer and Vincent (*J. P.,* 1899, xxv, 87) discovered that the injection of an aqueous extract of the hypophysis into the vein caused a rise of blood pressure rivalling, in height, that brought about by suprarenal extract and surpassing it in duration. The theory which was at one time advanced that the action of pituitary extract was similar to that of the suprarenal extract has been shown to be erroneous. The pressor principle is found only in the posterior lobe of the hypophysis and is not of the nature of an "internal secretion" as this is not a secreting structure.

The physiological effects of the posterior lobe of the pituitary body are stimulation of all the unstriped muscles, and increased secretion of the kidney and probably of the mammary glands. Among those muscles affected by the drug which are of importance from the standpoint of its clinical use, may be mentioned the circulatory, uterine, and intestinal muscles. The stimulant action upon the blood vessels is shown by the increase in arterial pressure which is apparently of purely vascular origin (Wiggers, *A. J. M. S.,* 1911, cxli, 142); the heart is not made up of unstriped muscle and does not appear to be stimulated by the drug. Repeated doses, even if intervals of an hour or two are allowed to elapse between their exhibition, do not produce the same degree of rise as the primary injection; indeed after a sufficient number of doses the drug exercises a depressor rather than a pressor influence. As was first shown by Ott and Scott (*Monthly Cylopedia and Med. Bull.,* August, 1909), the extract of hypophysis is one of the most powerful and certain stimulants for the uterine muscle that we possess. While it does increase the tonus of this muscle it seems to be especially efficient to increase the vigor of individual contractions. The effect of hypophysis on renal activity is very peculiar and not entirely understood. A considerable number of investigators have reported a definite diuretic effect. Hoskins and Means (*J. P. Ex. T.,* 1913, iv, 435) attribute this to a direct action upon the renal epithelium, but Knowlton and Silverman (*A. J. Phys.,* 1918, xlvii, p. 1) and Cushny and Lambie (*J. P.,* 1921, lv, p. 159) find that it is secondary to changes in the circulation of the kidney. On the other hand, in human beings at least, it usually caused a diminution in the urine. Abel and Geiling (*J. P. Ex. T.,* 1923, xxii, 289), although they report a diuretic action in rabbits, say "that the really characteristic and more important action on human beings is anti-diuretic." For review of literature on this subject see Mackersie (*J. P. Ex. T.,* 1924, xxiv, 83). Rees (*A. J. Phys.,* 1918, xlv, 471) believes that the diminution in the output of urine is due to delayed absorption of water from the intestines, but Brunn (*Cb. I. M.,* 1920, xli, 674) maintains that there is diminished ability of the kidney to excrete water. Certain it is that in cases of *diabetes insipidus* the injection of the present commercial pituitary extracts causes at least a temporary diminution in quantity and increased concentration of the urine.

The most common use of the hypophysis at present is as a uterine stimulant especially during *labor.* Although it is a very valuable drug in this condition when used circumspectly, there is no doubt that it is capable of doing great harm and has been greatly abused. While it seems less liable than ergot to cause tetanic spasm of the womb and there is therefore less danger of asphyxiation of the child (see Quigley, *J. A. M. A.,* 1915, lxiv, p. 1222), there have been reported several cases of rupture of the uterus from its injudicious use (Maxwell, *J. A. M. A.,* 1920, lxxiv, 1378). Before the head has passed the pelvic outlet its use in general should be avoided, although occasional circumstances may indicate its use at an earlier stage. For the treatment of *postpartum hemorrhage* it has the great disadvantage that its effects last only from one to two hours and there appears to be a tendency towards secondary relaxation. The promptness of its action, however, renders it in some cases superior to ergot; the two drugs may often be exhibited simultaneously, the pituitary for its primary, quick effect and the ergot to maintain the action. It has also been used to control *menorrhagia* and *metrorrhagia.* The effect of the extract of hypophysis on blood pressure suggests its use for the treatment of *surgical shock* and other forms of circulatory failure. Musser (*A. J. M. S.,* 1913, cxlvi, p. 208) has shown that even when exhibited by the mouth it causes a marked rise in blood pressure in human beings; Schmidt (*A. I. M.,* 1917, xix, 1059), however, failed to obtain any rise from solutions given orally although the same solutions were efficient when injected intramuscularly. Pohl (*D. M. W.,* 1921, xlvii, 1162) reports several cases of circulatory failure in which it was used with benefit. As an intestinal stimulant it has been highly lauded by many surgeons for the prevention or treatment of post-operative paralysis of the bowel (see Kirmisson, *B. A. M.,* 1918, lxxix, 82). The enormous increase in the secretion of milk which has followed its exhibition has naturally suggested its use as a lacteal stimulant both in human beings and also animals, but the present evidence seems to be that the primary stimulation is followed by a compensatory diminution of glandular activity (Rothlin, *Biochem. J.,* 1922, xvi, 3). Among other conditions for which it has been recommended may be mentioned *Graves's disease, hay fever, rickets, acromegaly,* and *tetany.* Its value in these conditions, if it has any, is probably dependent upon its influence over the nutritive processes and the whole gland is preferable. When, however, the effect upon the involuntary muscles is desired, whether of the uterus or arteries, we believe that the extract of the posterior lobe is to be preferred, since the anterior portion of the hypophysis has no effect upon these muscles and may exercise undesirable influences on the metabolism.

Dose, from one-half to two grains (0.032–0.12 Gm.).

Off. Prep.—Liquor Pituitarii, *U. S.*

PIX CARBONIS. N. F. (Br.)

COAL TAR Pix Carbon.

"The tar obtained as a by-product in the destructive distillation of coal in the manufacture of illuminating gas." *N. F.*

"Prepared Coal Tar is obtained by maintaining commercial coal tar at a temperature of 50° C. in a shallow vessel for one hour, stirring frequently." *Br.*

Pix Carbonis, *Br.;* Coal Tar; Gas Tar; Goudron Mineral, *Fr.;* Steinkohlenteer, *G.*

When bituminous coal is subjected to dry distillation, besides the incondensible gases which serve for lighting, and the charcoal left behind as coke, which is a valuable fuel, there are formed numerous other pyrogenic products, necessarily more or less varying in character and amount, not only according to the kind of coal used, but also with the varying circumstances of the decomposing process. Most of these newly formed bodies, all of which are volatilizable, are condensed into a dark thick liquid or semi-liquid substance called *coal tar.* Formerly this was considered as refuse matter, but from it are now prepared substances of great value in the arts and in medicine. We can give here only a brief review of the more important of these substances.

The composition of coal tar varies considerably with the temperature at which the distillation of the coal is effected, the yield of solid bodies and of gases being larger when the temperature is higher, while at a lower temperature the liquid portion of the tar is in increased amount.

When coal tar is submitted to fractional distillation it yields a number of valuable commercial products which are grouped as follows: *Light oils,* 2 to 8 per cent.; *middle* or *carbolic oils,* 8 to 10 per cent.; *heavy* or *creosote oils,* 8 to 10 per cent.; *anthracene oils,* 16 to 20 per cent. A residue of about 50 per cent. of pitch remains behind in the still. The light oils (sp. gr. 0.90 to 0.95) are redistilled and the higher boiling fractions added to the middle oils. The lighter fraction is purified by treatment with strong sulphuric acid in lead-lined vessels. The acid layer is recovered and worked up for *ammonium sulphate.* The oily layer is treated with caustic alkali to remove acid and is then fractionally distilled. The first runnings contain carbon disulphide, pentane, hexane and *acetonitrile,* the intermediate runnings consist mainly of *benzene* (*benzol*), the lower boiling portion being fractionated to produce pure benzene, the higher boiling fraction, containing toluene, xylene and cumene, being sold as solvent naphtha.

The middle oils contain principally *naphthalene, phenols* and *cresols.* The naphthalene is largely obtained by crystallization and is subsequently purified by sublimation. The mother liquors from the crystallization of the naphthaene contain 30 to 40 per cent. of phenolic bodies. This is purified by combining it with a weak solution of caustic soda and removing hydrocarbon impurities by blowing live steam through the solution. The phenols are then precipitated by the addition of acid and are fractionally distilled with zinc or silver condensing coils and the phenol (C_6H_5OH) separated from the *cresols* which occur as a liquid mixture of the three isomeric varieties.

The heavy creosote oils contain *naphthalene, dinaphthylene, methyl naphthalene, xylenol, naphthol* and *paraffins.* This fraction finds its principal uses in preserving timber which when impregnated with this complex liquid, sometimes under pressure is known as *creosoted timber.*

The anthracene oils contain some phenol, and a considerable amount of anthracene. This latter constituent is one of the most valuable fractions of coal tar. It is separated and purified from this fraction by cold crystallization and expression. There are also present in this fraction, small amounts of *methylanthracene, phenanthrene, diphenyl, naphthalene, pyrene, retene, carbazol, pyridine, quinoline, aniline,* etc.

The foregoing substances, all existing in coal tar, are properly known as coal-tar "fractions." The term "coal-tar products" is loosely applied to mean a "fraction," an "intermediate" or a "derivative." A coal-tar derivative does not exist in coal tar as such, but is prepared by chemical processes from some coal-tar fraction as the starting point. There are products of coal tar which are of importance as starting points in the manufacture of coal-tar derivatives. These are known as "intermediates."

Some of the coal-tar derivatives commonly used in medicine are also useful as intermediates and thus fulfil a double purpose.

Among the more important of these intermediates are the following: *Alphanaphthylamine,* $C_{10}H_7NH_2$; *alphanitronaphthalene,* $C_{10}H_7NO_2$; *aniline,* $C_6H_5NH_2$; *benzidine* (*p-p-diaminodiphenyl*), $NH_2C_6H_4\text{-}C_6H_4NH_2$. *Cleve's acids* (1 *naphthylamine-sulphonic acids*), $C_{10}H_6NH_2SO_3H$ 1:6 and 1:7; *cresotinic acid, cresotic, homosalicylic* or *toluic acid,* $C_6H_3CH_3OH.COOH$ 1:2:3; *dianisidine,* 4:3 $NH_2CH_3O.C_6H_3C_6H_3O.CH_3.NH_2$ 3:4; *dimethylaniline,* $C_6H_5N(CH_3)_2$; *dinitrobenzene,* $C_6H_4(NO_2)_2$ 1:3; *dinitrochlorobenzene,* $C_6H_3Cl(NO_2)_2$ 1:2:4; *dinitrophenol,* $C_6H_3OH(NO_2)_2$ 1:2:4; *dinitrotoluene,* $C_6H_3CH_3(NO_2)_2$ 1:2:4; *diphenylamine,* $(C_6H_5)_2NH$; *gamma acid* (2 *amino-8 naphthol-6-sulphonic acid*), $C_{10}H_5NH_2SO_3HOH.$ 2:6:8; *H acid* (1 *amino-8-naphthol-3-6 disulphonic acid*), $C_{10}H_{14}NH_2(SO_3H)_2OH$ 1:3:6:8; *Laurent's acid* (1 *naphthylamine-5-sulphonic acid*), $C_{10}H_6.NH_2SO_3H$ 1:5; *metanitroaniline,* $C_6H_4NH_2.NO_2$ 1:3; *metaphenylenediamine,* $C_6H_4(NH_2)_2$ 1:3; *metatoluenediamine,* $C_6H_3CH_3(NH_2)_2$ 1:2:4; *mononitrotoluenes,* $C_6H_4CH_3NO_2$ 1:2 and 1:4; *toluidines,* $C_6H_4CH_3NH_2$ 1:2 and 1:4; *monochlorobenzene,* C_6H_5Cl; *Nevile* and *Winter's acid* (1 *naphthol-4 sulphonic acid*), $C_{10}H_6OH.SO_3H$ 1:4; *nitrobenzene,* $C_6H_5NO_2$; *orthonitrotoluene,* $C_6H_4CH_3NO_2$ 1:2; *orthotoluidine,* $C_6H_4CH_3.NH_2$ 1:2; *para-aminophenol,* $C_6H_4OH.NH_2$ 1:4; *paranitroaniline,* $C_6H_4NH_2.NO_2$ 1:4; *paranitrochlorobenzene,* $C_6H_4Cl.NO_2$ 1:4; *paranitrotoluene,* $C_6H_4CH_3.NO_2$ 1:4; *paratoluidine,* $C_6H_4CH_3.NH_2$ 1:4; *picric acid,* $C_6H_2OH(NO_2)_3$ 1:2:4:6; *salicylic acid,* $C_6H_4OH.COOH$ 1:2; *sodium metanilate* (*sodium metaminobenzene sulphonate*), $C_6H_4NH_2SO_3Na$ 1:3; *sodium naphthionate* (*sodium 1 naphthylamine-4-sulphonate*), $C_{10}H_6NH_2SO_3Na$ 1:4; *sodium picramate,* $C_6H_2.ONa(NO_2)_2NH$ 1:2:4:6; *sulfanilic acid* (*para-aminobenzene sulphonic acid*), $C_6H_4NH_2SO_3H$ 1:4; *toluidine,* 4:3 $NH_2CH_3.C_6H_3\text{-}C_6H_3CH_3NH_2$ 3:4.

For description of some of the individual unofficial coal-tar colors and derivatives, see Part II.

Description and Physical Properties.—"A nearly black, thick liquid or semi-solid, heavier than water and possessing a characteristic, naphthalene-like odor and a sharp burning taste. It is only slightly soluble in water, to which it imparts its characteristic odor and taste and a faintly alkaline reaction. It is but partially dissolved by alcohol, acetone, methyl alcohol, or purified petroleum benzin; almost entirely dissolved by ether; entirely dissolved by benzene, carbon disulphide, or chloroform. On ignition it burns with a reddish, luminous and very sooty flame and upon strong heating is almost entirely consumed, leaving not more than 2 per cent. of ash." *N. F.*

Prepared coal tar is "a nearly black, viscous liquid, brown in very thin layers; heavier than *water.* Strongly empyreumatic characteristic odor. Almost entirely soluble in *benzene* and in *chloroform;* partially soluble in alcohol (90 per cent.), and in *ether;* very slightly soluble in *water.*" *Br.*

Uses.—Coal tar is occasionally used as a substitute for wood tar in external applications and according to Dind (*An. de Derm. et de Syph.,* 1909), has advantages over wood tar in that it is less irritant and less likely to produce nephritis or other toxic conditions after absorption. It is employed locally to relieve *itching* and to combat inflammation in such diseases as *lichen ruber, prurigo, eczema,* etc. It should not be used where the skin is infected with pyogenic cocci. It is most frequently applied in solution combined with saponin. (See *Liquor Picis Carbonis.*)

Off. Prep.—Liquor Picis Carbonis, *N. F., Br.*

PIX PINI. U. S. (Br.)

PINE TAR Pix Pin. [Pix Liquida U. S. P. IX]

"A product obtained by the destructive distillation of the wood of *Pinus palustris* Miller, or of other species of *Pinus* (Fam. *Pinaceæ*)." *U. S.* "Tar is a bituminous liquid, obtained by destructive distillation from the wood of Pinus sylvestris, *Linn.,* and other species of Pinus. Known in commerce as Stockholm tar." *Br.*

Pix Liquida, *Br.;* Pyroleum Pini; Resina Empyreumatica Liquida; Goudron végétal, Goudron, *Fr.;* Theer, *G.;* Pece liquida, *It.;* Brea de pino, Alquitran vegetal, *Sp.*

Pine tar is made by several processes. The most primitive method and one which is still used in the southern part of the United States is to pile pieces of stumps and of pine-wood waste, left over from lumbering operations, in a conical heap on a floor of hard-packed clay which slopes downward towards the center where is an opening connecting with a trench. The sides of the pile are covered with earth to prevent too much draft and the top of the pile ignited. During the slow combustion from above downwards, a certain amount of resins in the wood together with resin-like products of combustion, are melted by the heat and run down through the opening to the bottom of the floor and out into the trench where it is collected in barrels. It is obvious that in this method there will be a large loss of volatile substances. In Europe the burning of the wood is usually done in brick kilns with an opening at the side to admit fire and a two-way draining arrangement one of which leads upwards into a condenser to recover the more volatile substances and the other into a vessel to collect the liquid tar. A still more economical method is to heat the wood in large iron cylinders, in which case all the gases formed may be collected as well as the liquid distillate. The distillate yielded by any one of these methods, when allowed to stand, separates into two layers, a lower aqueous layer—containing chiefly acids of the methane series, like formic and acetic, and known as crude pyroligneous vinegar (see under *Acidum Aceticum*)—and an upper tarry layer which constitutes the substance recognized by the Pharmacopœias as pine tar. Any kind of wood may be carbonized in the manner above described, but when hard woods are used the tarry fractions are entirely different from official pine tar. (See *Creosote.*)

Pine wood when heated in retorts yields its products in the following proportions: Charcoal 24.2 per cent., tar 9.8 per cent., wood vinegar 42 per cent., gas 24.1 per cent. Cylindrical retorts are used, averaging in capacity one or two cords each.

Tar has an acid reaction, a peculiar empyreumatic odor, a bitterish, resinous, somewhat acrid taste, a color almost black, and a tenacious consistence intermediate between that of a liquid and that of a solid; by age it becomes granular and opaque.

Description and Physical Properties.—"A very viscid, blackish-brown, non-crystalline liquid. It is translucent in thin layers, becoming granular and opaque with age. It has an empyreumatic, terebinthinate odor and a sharp, empyreumatic taste. Pine Tar is heavier than water and is slightly soluble in it, the solution being pale yellowish to yellowish-brown and acid to litmus paper. Pine Tar is miscible with alcohol, ether, chloroform, glacial acetic acid, and fixed and volatile oils.

"Shake about 1 cc. of Pine Tar with 10 cc. of water for ten minutes, filter, and add 1 drop of ferric chloride T.S. to the filtrate. A green color is produced, rapidly changing to brown. Ash: not more than 0.25 per cent.

"Preserve in well-closed containers." *U. S.* "Dark brown or nearly black; semi-liquid; empyreumatic characteristic odor; heavier than *water. Water* shaken with it acquires a pale-brown color, sharp empyreumatic taste, and acid reaction; very dilute *T. Sol. of ferric chloride* colors the solution red. Tar is completely soluble in ten times its volume of *alcohol* (90 per cent.)." *Br.*

Tar yields a small proportion of its constituents to water, which is thus rendered medicinal, and is employed under the name of *tar water* (see below). Tar is dissolved by alcohol, ether, chloroform, and the volatile and fixed oils, and by a solution of potassium or sodium hydroxides. On spreading tar in a thin layer on a pane of glass it should present a homogeneous appearance. Those specimens which contain granular transparent masses should be rejected. These masses, which polarize brilliantly, are said to be *pyrocatechol.* Tar should have a specific gravity of 1.03 to 1.07; it should boil at from 250° to 400° C. Its reaction should be acid. *"Steam refined tar"* is tar which has been simply heated in steam caldrons and strained to remove foreign impurities.

Hirschsohn has suggested the following plan for the identification of different varieties of tar. (1) *Completely soluble in 95 per cent. acetic acid. Pine Tar.*—French turpentine dissolves it completely. The petroleum ether extract of the tar is colored greenish when shaken with a dilute solution of cupric acetate (1:1000). Chloroform and absolute ether dissolve it completely. *Beech Tar.*—Turpentine oil dissolves it only partially. The petroleum ether extract is not colored by copper acetate solution. Chloroform and absolute ether do not entirely dissolve it. (2) *Not completely soluble in 95 per cent. acetic acid. Juniper Tar.*—Turpentine oil dissolves it completely. Aniline dissolves it completely. The aqueous extract (1:20) yields a red coloration with dilute solution of ferric chloride (1:1000). *Birch Tar.*—Turpentine oil dissolves it completely. Aniline does not dissolve it completely. The aqueous extract is colored greenish by ferric chloride. *Aspen Tar.*—Benzene, chloroform, absolute ether, and olive oil dissolve it only partially. (*Ph. Ztg.*, 97, 396; *Ph. Z. R.*, 97.)

Composition.—When tar is distilled it yields a liquid portion (see *Oleum Picis Rectificatum* and *Acidum Aceticum*) and a black residue, *pitch* or *black pitch* (*pix nigra, resina nigra, pix navalis*). The latter has a faint tarry odor, is brittle at ordinary temperatures but softens by the warmth of the hand and melts in boiling water. It is soluble in alcohol or alkaline aqueous solutions. It consists chiefly of rosin and empyreumatic products of rosin.

Like all products of the destructive distillation of cellulose the composition of pine tar is largely phenolic. An extensive list of constituents that have been determined in pine tar are given in Hager's *Pharmaceutischen Praxis.* They are benzol, toluol, xylol, styrol, naphthalene, retene, paraffin, phenol, cresol, *phlorol* (ortho-ethyl-phenol), pyrocatechin, pyrogallic esters and *coerulignol* (methyl ether of 1:3:4 of prophyl-catechol). See also Williams, Lasselle and Reed (*J. I. E. C.*, 1925, 85).

Uses.—Tar owes its medicinal virtues chiefly to the phenol-like bodies which it contains; its effects resemble closely those of creosote, but it is less active and less liable to irritate the digestion. Its most important internal use is as a stimulating expectorant in subacute or chronic *bronchitis.* Externally it is widely employed as a stimulating and antiseptic application in various *skin diseases.* (See *Unguentum Picis Liquidæ.*)

In the middle of the 18th century tar water enjoyed a popular reputation, especially in England, as a panacea for nearly all the ills that afflict humanity—this reputation being due chiefly to the writings of the famous Bishop Berkeley—but because of the insolubility of tar no aqueous preparation can thoroughly represent the drug.

Pitch, the residue of tar after distilling off the oil was formerly employed as a local irritant in some sluggish skin diseases.

Dose, five to twenty grains (0.32–1.3 Gm.).

Off. Prep.—Unguentum Picis Pini, *U. S., Br.;* Glyceritum Picis Pini, *N. F.*

PLUMBI ACETAS. U. S., Br.

LEAD ACETATE Plumb. Acet. [Sugar of Lead]

"Lead Acetate contains not less than 85.31 per cent. and not more than 89.57 per cent. of $Pb(C_2H_3O_2)_2$, corresponding to not less than 99.5 per cent. of the crystallized salt [$Pb(C_2H_3O_2)_2.3H_2O$]." *U. S.* "Lead acetate may be obtained by dissolving lead oxide or lead carbonate in acetic acid. It contains not less than 99.5 per cent. of pure lead acetate, $Pb(C_2H_3O_2)_2$,-$3H_2O$." *Br.*

Acetas Plumbicus Neuter, Saccharum Saturni, Cerussa Acetata; Acétate neutre de Plomb, Sucre de Plomb, Sel de Saturne, *Fr.;* Plumbum Aceticum, *P. G.;* Bleiacetat Essigsaures Bleioxyd, Bleizucker, *G.;* Acetato neutro di piombo, Zucchero di Saturno, *It.;* Acetato plumbico neutro, Azucar de Saturno, *Sp.*

Preparation.—Lead acetate is obtained by two methods. By one method, thin plates of lead are placed in shallow vessels filled with distilled vinegar, in such a manner as to have a part of each plate rising above the vinegar, and these are turned from time to time, so as to bring different portions of the metallic surface in contact with the air. The metal, in the presence of the oxygen of the air, dissolves in the vinegar to saturation, and the solution is evaporated to the point of crystallization. This process is a slow one, but furnishes a salt which is perfectly neutral. The other method consists in dissolving, by the assistance of heat, litharge, in 60 per cent. acetic acid, in large wooden vats provided with mechanical stirrers. The acetic acid is heated to 60° C. and the litharge added by means of a distributing device. The oxide is quickly dissolved, and, when the acid has become saturated, the solution is permitted to clarify by subsidence in vessels provided with strips of lead which coming into contact with the solution remove small amounts of copper which may be present, and it is then transferred to other vessels to cool and crystallize. The crystals having formed, the mother waters are decanted, and, by evaporation, made to yield a new crop. These are generally yellow, but may be rendered white by repeated solutions and crystallizations.

Lead acetate is principally consumed in the arts of dyeing and calico printing, in which it is employed with alum, to form aluminum acetate, which acts as a mordant.

Description and Physical Properties.—"Colorless, shining, transparent, monoclinic prisms or plates, or heavy, white crystalline masses, or granular crystals. It has a faintly acetous odor, is efflorescent, and absorbs carbon dioxide on exposure to air. One Gm. of Lead Acetate is soluble in 1.4 cc. of water, and in 38 cc. of alcohol, at 25° C. One Gm. is soluble in about 0.5 cc. of boiling water. It is freely soluble in glycerin. When heated to 40° C., the salt loses its water of crystallization. When heated rapidly to 75° C., it liquefies in its water of crystallization, and at a temperature above 280° C. is decomposed, leaving a residue of finely divided metallic lead and lead oxide.

"An aqueous solution of Lead Acetate (1 in 10) is slightly alkaline to litmus paper, and responds to the reactions for lead, and for acetates.

"A solution of the salt (1 in 10) prepared with recently boiled, distilled water, is clear, or only slightly opalescent (*carbonate*) and yields with potassium ferrocyanide T.S. a precipitate which is neither blue nor red (*iron or copper*).

"Preserve in well-closed containers." *U. S.*

"Small, white, monoclinic prisms, or crystalline masses, slightly efflorescent. Acetous odor; taste sweet, astringent. Soluble in 2.5 parts of *water,* and in 30 parts of *alcohol* (90 per cent.). Aqueous solution slightly acid to *litmus,* clear, or with only a slight turbidity which disappears on the addition of *acetic acid.* Yields the *reactions* characteristic of lead and of acetates. Yields no characteristic *reactions* for silver, copper, arsenic, iron, zinc, calcium, chlorides, or nitrates. When 0.5 gramme is dissolved in *water* acidified with *acetic acid,* excess of *N/1 solution of oxalic acid* added, the precipitate collected, washed, transferred to a flask and decomposed with excess of *diluted sulphuric acid,* the mixture thus obtained, heated to 60° C., decolorises not less than 26.2 millilitres of *N/10 solution of potassium permanganate* (presence of not less than 99.5 per cent. of pure lead acetate, $Pb(C_2H_3O_2)_2,3H_2O$)." *Br.*

Exposed to the air, it effloresces slowly. In pure distilled water, free from carbon dioxide, it ought to dissolve entirely and form a clear solution. Commercial acetate is sometimes impure from the presence of lead sulphate and carbonate. In purchasing it large crystalline masses should be selected. Sulphuric acid, when added to a solution of lead acetate, produces instantly a precipitate of lead sulphate, and the disengaged acetic acid gives rise to vapors having the odor of vinegar. An important property of lead acetate is its power of dissolving a large quantity of lead monoxide. (See *Liquor Plumbi Subacetatis.*)

Assay.—"Dissolve about 5 Gm. of Lead Acetate, accurately weighed, in sufficient recently boiled distilled water to make exactly 100 cc. Mix 10 cc. of this solution with 50 cc. of tenth-normal oxalic acid in a 200 cc. measuring flask, agitate the mixture thoroughly for five minutes and fill the flask to the mark with distilled water. Filter, and titrate the residual oxalic acid in 100 cc. of the filtrate with tenth-normal potassium permanganate, the filtrate being previously acidulated with 10 cc. of sulphuric acid and warmed to 80° C. Each cc. of tenth-normal oxalic acid corresponds to 0.01626 Gm. of $Pb(C_2H_3O_2)_2$." *U. S.*

Incompatibles and Tests.—Lead acetate is decomposed by all acids, and by those soluble salts the acids of which produce with lead monoxide insoluble or sparingly soluble compounds. Acids of this character are sulphuric, hydrochloric, phosphoric, tannic, citric, and tartaric. It is also decomposed by lime water, and by ammonia, potassium and sodium hydroxide; the last two, if added in excess, dissolving the precipitate at first formed. It is decomposed by hard water, in consequence of the calcium sulphate, carbonates and sodium chloride which such water usually contains.

Uses.—Lead acetate is an active astringent with but slight irritant effect. It was formerly believed to exercise some peculiar local antiphlogistic action beyond its merely astringent powers and was very widely employed in all sorts of irritated conditions of the skin or mucous membranes. Internally it is also employed as an astringent in treatment of certain types of *diarrhea.* Its popularity as a remedial agent is rapidly on the wane, partly through loss of confidence in its virtues and partly because of the fear of lead poisoning.

As a local astringent over the unbroken skin it may be used in strengths of about 1 to 2 per cent. Over mucous membranes it should be more dilute, usually about 0.2 to 0.5 per cent.

In overdoses lead acetate may act as a local irritant to the stomach and cause severe, or occasionally, fatal intoxication. The usual symptoms are a metallic taste in the mouth followed by a burning sensation in the throat and, ordinarily within about half an hour, nausea and vomiting, the matters ejected being white and curdy from the presence of lead chloride. Later severe cramp-like pains in the abdomen may appear usually with constipation—although in some cases the bowels may be loose—the stools being black from the formation of lead sulphide. Afterwards there may be signs of involvement of the nervous system—as local paralysis—and in the fatal cases collapse develops after three or four days. The treatment consists in the immediate evacuation of the stomach, preferably by the stomach tube, or by the use of zinc sulphate or alum as emetics, followed by the administration of Epsom salts which acts both as a cathartic and chemical antidote. In the absence of a sulphate, sodium chloride may be used as a chemical antidote, although not quite as efficient.

Dose, one to three grains (0.065–0.20 Gm.).

PLUMBI IODIDUM. N. F., Br.

LEAD IODIDE Plumb. Iod.

"Lead Iodide contains, when dried over sulphuric acid for 24 hours, not less than 99 per cent. of PbI_2(461.04)." *N. F.*

"Lead Iodide, PbI_2, may be obtained by the interaction of aqueous solutions of lead nitrate or acetate and potassium iodide." *Br.*

Ioduretum Plumbicum, Plumbum Iodatum, *Fr. Cod.;* Iodure de Plomb, *Fr. Cod.;* Jodblei, *G.;* Yoduro plumbico, *Sp*

Neither the present Br. nor N. F. give a process for lead iodide; that of the Br. 1885 was as follows:

"Take of Nitrate of Lead, Iodide of Potassium, each *four ounces* [avoirdupois]; Distilled Water *a sufficiency.* Dissolve the Nitrate of Lead, by the aid of heat, in a pint and a half, and the Iodide of Potassium in half a pint of the Water, and mix the solutions. Collect the precipitate on a filter, wash it with Distilled Water, and dry it in a warm place." *Br.*, 1885. The theoretical quantities of lead nitrate and potassium iodide are almost precisely equal quantities. The proportions should be as nearly as possible those of exact saturation. An excess of the potassium iodide, independently of the waste, has the disadvantage of holding a portion of the lead iodide in solution, while, according to Christison, an excess of lead over the iodine disposes to the formation of the lemon-yellow insoluble lead oxyiodide. As lead iodide is slightly soluble in cold water, it is desirable to use as little of the solvent as will answer, and hence the comparatively small proportion of water employed.

The Br. describes it as: "a heavy, bright-yellow powder. Soluble in about 2000 parts of cold *water*, and in about 200 parts of boiling *water*, from which it is deposited in golden-yellow crystalline scales as the solution cools; entirely soluble in *solution of ammonium chloride*. Yields the reactions characteristic of lead and of iodides. Yields no characteristic *reactions* for nitrates or acetates." *Br.*

Description and Physical Properties.—"Lead Iodide occurs as a heavy, bright yellow powder, without odor or taste; permanent in the air. One Gm. dissolves in about 1300 cc. of water at 25° C. and in about 200 cc. of boiling water, separating from the latter solution on cooling in brilliant, golden yellow crystalline laminæ; very slightly soluble in alcohol; soluble, without color, in solutions of the fixed alkalies, in concentrated solutions of the alkali acetates, of potassium iodide, and of sodium thiosulphate, and in a hot solution of ammonium chloride.

"When moderately heated, the salt fuses to a thick, reddish brown liquid, which congeals, on cooling, to a yellow, crystalline mass. At a higher temperature it is decomposed, with the evolution of violet vapors of iodine, leaving a lemon-yellow residue of lead oxyiodide.

"Triturate 1 Gm. of the salt with 2 Gm. of ammonium chloride and 2 cc. of distilled water; a nearly white mixture results. Transfer this to a test tube, and heat in a water bath for a few minutes; a clear, almost colorless solution is formed (*chromate and other insoluble foreign salts*). On cooling this solution, a solid mass of nearly colorless, fine, silky crystals is produced, and on adding water or diluted sulphuric acid to this mass, yellow Lead Iodide separates. Add 0.1 Gm. of the salt to 5 cc. of distilled water, and heat the mixture until it boils; cool the liquid and filter it into a test tube of about 40 cc. capacity, then add 5 cc. of sodium hydroxide T.S. and about 0.2 Gm. of aluminum wire; insert in the upper portion of the test tube a pledget of purified cotton, and over the mouth place a piece of moistened red litmus paper and then heat the tube on a water-bath during fifteen minutes; no blue coloration of the paper will be discernible (*nitrate*). Boil 1.5 Gm. of Lead Iodide for a few minutes with 15 cc. of distilled water, cool and filter. To 5 cc. of the filtrate add a slight excess of silver nitrate T.S., then a slight excess of hydrochloric acid and filter. Neutralize the filtrate with ammonia water and add a drop of ferric chloride T.S. No red color is produced (*acetate*). To another 5 cc. portion of the filtrate add an excess of hydrogen sulphide T.S., filter, evaporate to dryness and ignite; not more than 0.002 Gm. of residue remains.

"**Assay.**—Dry about 1 Gm. of Lead Iodide over sulphuric acid for 24 hours. Dissolve about 0.5 Gm. of the dried lead iodide, accurately weighed, in 30 cc. of sodium hydroxide T.S., heating on the water-bath if necessary, to facilitate solution. Cool the solution, add 40 cc. of tenth-normal silver nitrate and follow it with diluted nitric acid until the solution is slightly acid, and add 15 cc. more of the nitric acid. Now titrate the excess of silver nitrate with tenth-normal potassium thiocyanate, using 3 cc. of ferric ammonium sulphate T.S., as indicator, and deduct from the volume of tenth-normal silver nitrate consumed the volume required for the chloride present in the 30 cc. of sodium hydroxide T.S. Each cc. of tenth-normal silver nitrate corresponds to 0.023047 Gm. of PbI_2.

"Preserve it in well-closed containers, protected from light." *N. F.*

It is freely soluble in a concentrated solution of sodium acetate. It should be kept excluded from the light. It is stated by Engelhardt that iodine is separated from lead iodide by ferric and cupric chlorides, while the other metallic chlorides have no such effect, producing compounds of iodides of the metal employed with lead chlorides.

Uses.—This compound was supposed to have the resolvent properties of iodine, combined with the antiphlogistic powers formerly attributed to lead, and was employed in the treatment of *scrofulous tumors* and other indolent swellings. According to Cogswell, if given for some time in small doses, it produces the effects of lead, but not those of iodine, upon the system. It is more dangerous than useful. It is used only as an external remedy. The plaster of lead iodide was dropped from the British Pharm., 1914, but the ointment was retained.

Off. Prep.—Unguentum Plumbi Iodidi, *N. F.*, *Br.*

PLUMBI MONOXIDUM. U. S. (Br.)

LEAD MONOXIDE Plumb. Monoxid. [Plumbi Oxidum U. S. P. IX, Litharge]

"Lead Monoxide, when freshly ignited, contains not less than 97 per cent. of PbO." *U. S.* "Lead Oxide, PbO, may be obtained by the action of air on melted lead." *Br.*

Plumbi Oxidum, *Br.;* Oxide of Lead; Yellow Oxide of Lead; Plumbi Oxidum Semivitreum; Oxidum Plumbicum; Plumbum Oxydatum Fusum, *Fr. Cod.;* Oxide de Plomb Fondu, Protoxide de Plomb, *Fr.;* Lithargyrum, *P. G.;* Bleiglätte, Bleioxyd, *G.;* Litargirio, *It.*, *Sp.*

Lead monoxide occurs in two forms. First, an amorphous yellowish powder called *massicot* which is prepared by heating lead carbonate to a low redness. The second, litharge, is a semi-crystalline product prepared at a much higher temperature. Practically all of the litharge of commerce is obtained as a secondary product in the process for extracting silver from argentiferous galenas in the process known as "cupellation." In this the alloy of silver and lead is heated in a reverberatory furnace, the floor of which is covered with either bone-ash or a special clay and the wall provided with openings for an air-blast. When the metal is melted a current of air is blown over the surface which oxidizes the lead and the resulting oxide floats on the surface of the molten metal and is removed either by means of ladles or allowed to run off through lateral openings. When obtained in this manner it forms a semi-crystalline mass sometimes known as *vitrified lead oxide.*

The product of the latter process, which is known as litharge, varies in color from a pale yellow to a shade of orange; massicot usually has a redder tint, sometimes being almost scarlet, and is occasionally referred to as "red litharge." This red color was at one time taken to indicate the presence of minium but Leblanc has shown that the two varieties of litharge differ in color, structure, and density only, and not in chemical composition.

Description and Physical Properties.—"A heavy, yellowish or reddish-yellow powder, or minute scales, without odor or taste. On exposure to the air it slowly absorbs moisture and carbon dioxide. Lead Monoxide is almost insoluble in water, to which, however, it imparts a faintly alkaline reaction. It is insoluble in alcohol. The Monoxide is dissolved by acetic acid, by diluted nitric acid, and by warm solutions of the hydroxides of fixed alkalies.

"When heated, the Monoxide becomes darker in color, but assumes its original color on cooling. It fuses at a red heat. When heated in contact with charcoal, it is reduced to metallic lead. A solution of the Monoxide in diluted nitric acid (1 in 10) is colorless, and when nearly neutralized by ammonia T.S. responds to the reactions for lead.

"Shake 5 Gm. of the Monoxide in a small flask with 5 cc. of distilled water and add 20 cc. of acetic acid. Boil the mixture for a few minutes, filter, wash the insoluble residue thoroughly with diluted acetic acid, and dry at 110° C.: the residue weighs not more than 0.10 Gm. When strongly heated in a porcelain crucible, the Monoxide loses not more than 4 per cent. of its weight (*carbonate or moisture*).

"Preserve in well-closed containers." *U. S.*

"Heavy scales, or powder, of a pale yellowish-red color. Soluble in *diluted nitric acid* and in *acetic acid* with but slight effervescence, leaving not more than traces of insoluble residue. Yields the reactions characteristic of lead. Yields no characteristic *reactions* for copper, and not more than the slightest *reactions* for iron." *Br.*

It slowly attracts carbon dioxide from the air, and contains more of this acid the longer it has been exposed. It is on this account that it commonly effervesces slightly with the diluted acids. It has the property of decolorizing wines, when agitated with them. When heated with the fats and oils, in connection with water it saponifies them. (See *Emplastrum Plumbi Oxidum.*) As it occurs in commerce, it frequently contains iron, copper, and a little silver and silica. It may be purified from iron and copper by digestion in diluted sulphuric acid. In choosing litharge, samples should be selected which are free from copper and from mechanical impurities. Copper is detected if upon adding potassium ferrocyanide to a nitric acid solution of the litharge a brown instead of a white precipitate is produced. The carbon dioxide which it contains is variable, but its average amount is about 4 per cent. Lead peroxide and red lead in litharge may be detected by heating it in a test tube with sodium chloride and potassium bisulphate and introducing a slip of paper colored blue by indigo. If either of these oxides be present, the paper will be bleached by the chlorine evolved.

Assay.—"Dissolve about 0.4 Gm. of freshly ignited Lead Monoxide, accurately weighed, in 2 cc. of glacial acetic acid and 25 cc. of recently boiled, distilled water, in a 200 cc. volumetric flask, and mix the solution with 50 cc. of tenth-normal oxalic acid. Fill the flask to the 200 cc. mark with distilled water, mix well, filter through a dry filter into a dry flask, rejecting the first 20 cc. of filtrate, and titrate the residual oxalic acid in 100 cc. of the filtrate with tenth-normal potassium permanganate, the filtrate being previously acidulated with 20 cc. of diluted sulphuric acid, and warmed to 80° C. Each cc. of tenth-normal oxalic acid corresponds to 0.01116 Gm. of PbO." *U. S.*

Uses.—Litharge is never used internally, but is employed in several pharmaceutical operations, and forms an ingredient in various external applications, used for abating inflammation, and for other purposes. In the arts it is employed in the glazing of pottery, in painting to increase the drying property of oils, and as an ingredient in flint glass.

Off. Prep.—Emplastrum Plumbi Oleatis, *U. S.* (*Br.*)*;* Glycerinum Plumbi Subacetatis, *Br.;* Liquor Plumbi Subacetatis, *U. S.* (*Br.*).

PLUMBI OXIDUM RUBRUM. N. F.

RED LEAD OXIDE Plumb. Oxid. Rubr. [Red Lead]

"Lead orthoplumbate [Pb_2PbO_4 (685.6)] usually with some unconverted lead monoxide (PbO), corresponding to not less than 31 per cent. of lead dioxide (PbO_2)." *N. F.*

Lead Oxide, Red, Plumbum Hyperoxydatum Rubrum; Plumbas Plumbicus; Red Lead; Minium, Deutoxide de Plomb, Oxide Rouge de Plomb, Minium, *Fr.;* Mennige, *G.;* Minio, *It., Sp.*

As stated on page 867, lead may act as a base, or may unite with hydrogen and oxygen to form an acid radical. In the present salt the lead is considered to be in both conditions. That is, it is a plumbate. *Orthoplumbic acid* has the hypothetical constitution H_4PbO, but is unknown except in the form of its salts. When the hydrogen of this acid is replaced by two atoms of the bivalent lead, we have *lead orthoplumbate* or minium.

Minium is prepared by carefully heating lead monoxide to a temperature of 450° C. By some it is considered a mixture of lead monoxide and peroxide ($2PbO,PbO_2$). This view is rendered plausible by the fact that nitric acid dissolves out PbO and leaves a residue of PbO_2. It has a specific gravity of 8.6 to 9.0.

Red lead in the arts is used chiefly as a paint, for protecting metal surfaces, in the manufacture of flint glass, and in cements for metal joints.

Description and Physical Properties.—"Red Lead Oxide occurs as a heavy, orange-red powder without odor or taste. On exposure to the air it slowly absorbs moisture and carbon dioxide. Almost insoluble in water, insoluble in alcohol, but dissolved by an excess of glacial acetic acid; also dissolved by lactic acid with the evolution of carbon dioxide and the odor of acetaldehyde.

"When heated in a porcelain crucible, Red Lead Oxide at first changes color from red to a violet and then to a blackish tint, and regains its original color on cooling, but, when the heating is continued, it slowly decomposes, forming lead monoxide and oxygen. When heated in contact with charcoal, it is reduced to metallic lead.

"Treat 5 Gm. of Red Lead Oxide with 50 cc. of diluted nitric acid; little effervescence results (*carbonate*), and a brown, insoluble residue of lead dioxide (PbO_2) remains, which, upon the addition of solution of hydrogen dioxide, dissolves with the evolution of oxygen, forming a colorless solution. Boil this solution for fifteen minutes, cool, and filter; the undissolved residue weighs not more than 0.1 Gm. (*silicate or lead sulphate*). On completely precipitating a portion of the solution from the foregoing test, representing 1 Gm. of red lead oxide, with hydrogen sulphide, the filtrate on evaporation yields not more than 0.01 Gm. of residue. Separate portions of the solution obtained in the last test yield with hydrogen sulphide T.S. a black precipitate; with potassium iodide T.S., a yellow precipitate; and with diluted sulphuric acid, a white precipitate; the latter two precipitates being soluble in a solution of sodium hydroxide (1 in 4). From a solution of 0.5 Gm. of Red Lead Oxide in diluted nitric acid, obtained by the aid of solution of hydrogen dioxide, precipitate the lead with sulphuric acid and filter the mixture. After the addition of an excess of ammonia water this filtrate does not develop more than a slight, bluish tint (*copper*), or yield more than traces of a reddish brown precipitate (*iron*). Heat a mixture of 1 Gm. of Red Lead Oxide with 50 cc. of distilled water to boiling, cool, and filter. The filtrate is colorless, is not more than faintly alkaline to litmus, and, when evaporated to dryness, leaves not more than 0.01 Gm. of residue (*soluble impurities*).

"**Assay.**—Add about 1 Gm. of Red Lead Oxide accurately weighed, to a cool solution of 40 Gm. of crystallized sodium acetate and 2 Gm. of potassium iodide in 50 cc. of 50 per cent. acetic acid, agitate the mixture until all of the Red Lead Oxide has dissolved and then titrate the solution with tenth-normal sodium thiosulphate. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.01195 Gm. of lead dioxide (PbO_2). Each Gm. of Red Lead Oxide corresponds to not less than 25.9 cc. of tenth-normal sodium thiosulphate." *N. F.*

Minium is used externally, and almost solely in the form of the camphorated brown plaster.

Off. Prep.—Emplastrum Fuscum Camphoratum, *N. F.;* Unguentum Fuscum, *N. F.*

PLUMBUM

LEAD

Plomb, *Fr.;* Blei, *G.;* Lood, *Dutch;* Piombo, *It.;* Plomo, *Sp.*

Lead is not official in its metallic state, but enters into a number of important medicinal preparations. It occurs in nature in galena, PbS; in cerussite, $PbCO_3$; in *crocoite*, $PbCrO_4$; in *wulfenite,* $PbMoO_4$; and in *anglesite,* $PbSO_4$. The greater quantity is obtained from *galena* which is abundant in the United States, Spain, Germany and England; less important deposits are found in Venetia, Lombardy and Tuscany. The extraction is effected either by melting the ore in contact with charcoal, or, in the case of pure galenas, by what is termed the *air reduction* process. In this case the galena is first roasted, when it is part changed into oxide, PbO, and sulphate, $PbSO_4$. The doors of the furnace are then closed, and the unchanged sulphide reacts with both the oxide and the sulphate as follows:

$$2PbO + PbS = 3Pb + SO_2$$
$$PbSO_4 + PbS = 2Pb + 2SO_2$$

whereby all the lead is obtained in the metallic state. Lead is also successfully obtained by electrolysis directly from the galena. This is reduced at the cathode of an electrolytic cell, while hydrogen sulphide is formed at the same time and may be collected or burned to form sulphur dioxide, which is then utilized. This process is now in operation at Niagara Falls. The richest and most extensive mines of galena are found in this country. The non-argentiferous lead region of the United States extends in length from Wisconsin in the north to the Red River of Arkansas in the south, and in breadth about one hundred and fifty miles, being chiefly in the State of Missouri, while Utah, Idaho, Montana, and Colorado furnish argentiferous galena.

Properties.—Lead is a soft, bluish-gray, non-elastic and very malleable metal, presenting a bright surface when newly melted or cut. It has a perceptible taste, and a peculiar odor when rubbed. It undergoes but little change in the air, but is acted on by the combined influence of air and water, which produces the hydroxide, which is afterwards changed, in part, into carbonate, by absorbing carbon dioxide from the atmosphere. Waters containing much free CO_2 dissolve lead and acquire poisonous qualities. The chemical effect of water on the metal is greater in proportion as the water is purer. Aqueous vapor passed through leaden pipes has a similar corroding effect, which is greater as the lead is purer. Spring and river water act on lead differently according to the predominating constituents in the water. Hard water forms a protective coating of lead carbonate or lead sulphate on the inner surface of pipes through which it flows, but this protective condition disappears in waters which have been treated with chlorine or hypochlorites for the purpose of purification. Stalmann has satisfied himself, by experiment, that an extremely minute quantity of ammonia or of nitric acid will very much promote the action of water upon lead—a millionth of ammonia being sufficient for the purpose. (*J. P. C.*, iv, 467.) Metallic lead is liable to the attacks of certain insects, which bore into and sometimes through it, not using it as food, but apparently in search of secure places of retreat for future development. Its sp. gr. is 11.4, melting point 327° C., and atomic weight 207.20. Exposed to a stream of oxygen on ignited charcoal, it burns with a blue flame throwing off dense yellow fumes. The best solvent of lead is nitric acid, but the presence of sulphuric acid destroys, and that of hydrochloric acid lessens, its solvent power, on account of the insolubility of the lead sulphate and chloride. Lead forms a suboxide, Pb_2O, a monoxide, PbO, a sesquioxide, Pb_2O_3, a dioxide, PbO_2, and a compound of the monoxide and the dioxide, lead orthoplumbate, Pb_3O_4. The monoxide and the last named compound are official (see *Plumbi Monoxidum* and *Plumbi Oxidum Rubrum*).

The *sesquioxide*, discovered by Winckelblech, is unimportant. The *dioxide*, PbO_2, called also *puce* oxide from its flea-brown color, may be obtained by treating red lead with nitric acid. The acid takes up the monoxide and leaves the dioxide, which may be purified by washing with boiling water. A more productive process is to precipitate four parts of lead acetate by three of sodium carbonate, and then to pass into the thin pasty mass of lead carbonate a stream of chlorine, which converts the monoxide of the carbonate into the brown dioxide. (F. Wöhler.) Solution of chlorinated soda may be conveniently employed to furnish the necessary chlorine. Lead dioxide is a tasteless powder, of a dark brown color. When heated to redness it loses half its oxygen and becomes monoxide. It consists of one atom of lead and two atoms of oxygen. It is further described among the Pharmacopœial reagents. (See Part III.)

Lead forms two classes of compounds in one of which it acts as a base (as illustrated by the official salts of lead), and in the other of which it is contained in the acid group forming a class of compounds known as *plumbates* and *plumbites*. Lead combines with iodine, forming the official lead iodide. The acetate is also official.

The best tests for lead are hydrogen sulphide or a solution of potassium iodide. The former produces a black precipitate of lead sulphide, the latter a yellow one of lead iodide.

Poisoning.—In concentrated form and sufficient amount the soluble preparations of lead are violent irritant poisons. (See *Plumbi Acetas.*) The insoluble preparations of lead are incapable of acting as acute irritant poisons, but are the common causes of a chronic poisoning. The most common form of the poisoning, the so-called *colica pictonum*, is very common among painters, makers of white lead, and other artisans who work in the metal. It is, however, also frequently seen in other persons, into whom the lead finds entrance in almost innumerable ways, especially with drinking water and food. Colica pictonum usually begins with dyspeptic symptoms and obstinate constipation, associated with violent pain of a twisting character, which seems to center round the umbilicus; the abdominal walls are spasmodically retracted.

Accompanying these symptoms there is loss of appetite, pallor, lassitude, and failure of the general health. The stools are whitish and usually constipated, although occasionally there is diarrhea. A characteristic symptom is a blue line situated upon the margin of the gums where they join the teeth, due to the deposit of the lead sulphide. This blue line, if present, is pathognomonic, but may be absent even in the most severe cases. Basophilic degeneration of the red blood cells can be found in the majority of cases, and if present is a very suggestive symptom. The pulse is usually slow and hard.

Various symptoms of disorder of the nervous system or of nutrition may occur later. Occasionally these nervous disturbances are the sole evidence of the intoxication, although more frequently they are either accompanied with, or preceded by, the typical lead colic. The most characteristic of the nervous phenomena is the double wrist drop due to paralysis of the extensors of the fore arm, and associated with wasting and degenerative changes in the muscles involved. Rarer manifestations are: paraplegia simulating anterior poliomyelitis; cerebritis with wild delirium and sometimes convulsions; occasionally arthritis very much like that of typical gout may be seen. Chronic lead poisoning in rare cases may take on many other forms; indeed, it has been said that lead poisoning may simulate any known nervous disease. A peculiar form of lead poisoning occurred among the workers in the manufacture of *tetraethyl lead*, a compound used under the name of "ethyl gas" as an automobile fuel. These cases were characterized by a predominance of cerebral manifestations and an absence of the intestinal symptoms. (For description of these cases see Hamilton, *J. A. M. A.*, 1925, lxxxv, 1481, and Kehoe, *Ibid.*, lxxxvi, 108.) For further information on chronic lead poisoning, see *A. J. M. S.*, 1921, clxii, 833; *J. A. M. A.*, 1911, lvi, p. 1240; and 1921, lxxvi, 835.

The diagnosis of chronic lead poisoning is of the utmost importance, but sometimes of great difficulty. The blue line upon the gums, if present, is practically pathognomonic, but its absence is of no negative value. Extensive degeneration of the blood corpuscles is also a symptom of great diagnostic importance, but may be absent in even severe cases. In doubtful cases a chemical examination of the urine for the presence of lead should be made. It must be remembered, however, that the presence of the metal does not prove that the case is one of lead poisoning; lead has been found in the urine of many persons in apparently normal health. As the elimination of lead through the kidneys is hastened by the administration of potassium iodide it is generally advisable to give this salt two or three days before the collection of the sample for examination.

The treatment of chronic lead poisoning resolves itself into three divisions: to stop the ingestion of the poison, to hasten its elimination, and to relieve symptoms. The most important step in the first of these is to find the source. While in the majority of instances the disease is an occupational one, yet in some cases much ingenuity is required to trace its origin. It has been attributed in obscure cases to the use of various cosmetics containing lead, to lead-foil around chewing tobacco or confectionery, to biting of silk thread which has been weighted with lead, to the use of improperly glazed earthenware vessels, etc., but outside of workers in the metal it most commonly obtains entrance into the body with the drinking water. The daily use of magnesium sulphate serves the double purpose of keeping the bowels open and of precipitating any lead which may be eliminated into the intestinal tract. For the purpose of aiding in the excretion of the metal the most important single measure is the administration of potassium iodide which forms a soluble compound with the metal. The use of sweat baths containing sulphur has also been recommended.

Warm *sulphuretted baths* may be provided by dissolving four ounces of potassium sulphide in thirty gallons of water, in a wooden tub. These baths cause discoloration of the skin, from the formation of lead sulphide, and should be repeated every few days, until this effect ceases to be produced. After each bath the patient should be well washed with soap and water with the aid of a flesh brush, in order to remove the discoloration. By proceeding in this way, the lead on the skin, or in its pores, is rendered insoluble and inert, and at the same time removed.

The manifestations are so protean that it is impossible to consider here all the measures for relief of symptoms. For the colic the most generally useful drug is belladonna in full dose. If the pain is very severe morphine may be given which acts not only by its direct analgesic effect, but by relaxing the intestinal spasm.

We have seen life apparently saved in a violent attack of lead cerebritis by free venesection and the injection of physiological salt solution.

PODOPHYLLI INDICI RESINA. Br.

INDIAN PODOPHYLLUM RESIN [Podophyllum Emodi Resin]

"Indian Podophyllum Resin is a powdered resin prepared by the same process as that described under 'Podophylli Resina,' employing Indian Podophyllum Rhizome in place of Podophyllum Rhizome. It possesses the characters and responds to the tests described under 'Podophylli Resina.'" *Br.*

(See *Podophylli Indici Rhizoma.*)

The rhizome of the Indian Podophyllum has become a commercial article and appears to have been largely used in the making of podophyllin. The question as to the relative yield of the Indian and American plants is a matter of great importance to the manufacturer, it usually being stated that the Indian rhizome is twice as active. Some years since Dyrock and Hooper obtained 12 per cent. of resin from *P. Emodi;* Umney, working with large quantities (*P. J.*, Sept., 1902), got out 11.4 per cent.; since then John Barclay (*P. J.*, 1903, lxx) was not able to obtain a greater yield than 6.69 per cent. Umney, commenting on this, believes that of late years the Indian plant gives a much smaller product than formerly, probably on account of the time of year in which it is now dug. In regard to the therapeutic interchangeability of the two resins it has been demonstrated by the researches of Dunstan and Henry (*Proc. Chem. Soc.*, March, 1898) and J. C. Umney that the active substances, podophyllotoxin and podophyllo-resin, found in the American Podophyllum are also present in the Indian resin, but it is not assured that the proportion of these active principles is the same in the two resins. The proportion of podophyllotoxin in the Indian rhizome is generally considerably higher than in the American, ranging from 1 to 4 per cent. In the present state of our knowledge, the manufacturer is certainly not justified in putting upon the market a resin made from the Indian plant unless it is plainly marked as the Indian podophyllin. Distinguishing between the two resins has become a question of importance. The presence of a yellowish-green color does not, as has been affirmed, prove that a podophyllin is impure or of Indian origin. The test of solubility is also uncertain. The Indian podophyllin, properly prepared, is freely soluble in alcohol. It is commonly stated that the true podophyllin will dissolve in ammonia (1 to 100). The Indian species is seemingly much less soluble in ammonia than this, but a properly prepared official resin does not always come up to this standard. E. J. Millard (*P. J.*, lx) states that the Indian resin strikes with strong sulphuric acid an orange to red color, the official resin yellow coloration, tending to brown, but especially commends the following test:

To six grains (0.4 Gm.) of the resin in a test tube add one fluidrachm (3.75 cc.) of diluted alcohol sp. gr. 0.920, and eight or ten drops (0.4–0.5 cc.) of solution potash, B. P.; shake gently by rotating the test tube. In case of the Indian resin, the mixture becomes in a few seconds a semi-solid gelatinous mass, so that the test tube can be safely inverted. If this does not occur quickly, the mixture should be heated until it just begins to boil, and when cold it will be found to have gelatinized. The American resin similarly treated gives a dark fluid that shows no signs of gelatinizing even after standing for days. The Indian Podophyllum Resin is used for the same purposes as the American. (See *Resina Podophylli.*)

Dose, one-fourth to one grain (0.016 to 0.065 Gm.).

PODOPHYLLI INDICI RHIZOMA. Br.

INDIAN PODOPHYLLUM RHIZOME [Podophyllum Emodi Rhizome]

"Indian Podophyllum Rhizome is the dried rhizome and roots of Podophyllum Emodi, *Wall.*" *Br.*

Podophyllum Emodi (Fam. *Berberidaceæ*) is a perennial herb which is indigenous to Thibet and Afghanistan. It somewhat resembles our American Podophyllum. The stem rises to a height of six or twelve inches before the opening of the leaves which attain a diameter of six to ten inches when fully expanded. The latter are curiously reflexed, droop umbrella-like and are often spotted. The plant produces in May a large sub-sessile, pinkish-white, flower which arises from the axil of one of the leaves, maturing before the latter are fully expanded. The fruit is about the size of a small lemon, of a bright orange color, being fully ripe in about August or September.

The contorted rhizome of *Podophyllum Emodi* is from six to eight mm. in thickness, crowded above with numerous buds or short branches, marked by depressed oval or circular scars, and giving off numerous simple rootlets from the whole of the under surface. The terminal bud is enclosed in whitish papery sheaths. The color is earthy-brown. The fracture is white, short, and mealy, or yellow and horny, exhibiting a circular arrangement of yellow vascular bundles, and bounded on the outside by a thin brown cortical layer.

"Rhizome cylindrical or flattened, contorted, earthy-brown; usually about ten millimetres thick; below with numerous root-scars, or with stout roots and crowned with the short remains of aerial stems, bearing cup-shaped scars. In transverse section, pale-brown and starchy or horny, with a ring of radially elongated wood-bundles. Slight odor; taste bitter and acrid." *Br.*

It may be used for the same purposes as podophyllum, but is official only as a source of the resin.

Off. Prep.—Podophylli Indici Resina, *Br.;* Tinctura Podophylli Indici (from Resin), *Br.*

PODOPHYLLUM. U. S. (Br.)

PODOPHYLLUM Podoph. [Mandrake, May Apple]

"Podophyllum consists of the dried rhizome and roots of *Podophyllum peltatum* Linné (Fam. *Berberidaceæ*). Podophyllum yields not less than 3 per cent. of the resin of podophyllum." *U. S.* "Podophyllum Rhizome is the dried rhizome and roots of Podophyllum peltatum, *Linn.*" *Br.*

Podophylli Rhizoma, *Br.;* Podophyllum Root, Wild Mandrake, Devil's Apple, Umbrella Plant, Vegetable Calomel, *Mandrake,* American Mandrake, Wild Lemon, Ground Lemon, Hog Apple, Indian Apple, Raccoon Berry, Duck's Foot; Rhizome de Podophyllum, *Fr.;* Fussblattwurzel, *G.;* Podofillo, *It.;* Podofilo (Rizoma de), *Sp.*

Podophyllum peltatum is an indigenous perennial herb having a prolifically branching rhizome system. Each rhizome branch is horizontal, usually several feet in length, about one-quarter of an inch thick, brown externally, smooth, jointed, and furnished with roots at the joints. Two kinds of stems arise from separate joints of the rhizome and its branches, *viz.,* the flowerless and the flowering stems. The flowerless stem terminates in a peltate leaf having 7 to 9 wedge-shaped lobes. The flowering stem bifurcates at its summit to form two stalked, 5- to 7-lobed leaves from the fork of which a stalked, pendulous, white flower arises. The calyx is composed of six oval, obtuse concave, fugacious sepals. The corolla has from six to nine white, fragrant petals, which are obovate, obtuse, concave, with delicate transparent veins. The stamens are from thirteen to twenty, shorter than the petals, with oblong yellow anthers, of twice the length of the filaments. The stigma is sessile, fleshy and undulate. The fruit is a large oval berry, crowned with the persistent stigma, and containing a sweetish and slightly acrid fleshy pulp, in which about twelve ovate seeds are embedded, each inclosed in a fleshy aril. It is, when ripe, of a lemon-yellow color diversified by round brownish spots. Two species of the genus *Podophyllum* are known as growing in China while *Podophyllum Emodi,* which inhabits the interior ranges of the Himalayas and is very abundant in Cashmere is recognized in the Br.

The May apple is extensively diffused through the Eastern United States, growing luxuriantly in colonies, in moist open places of shady woods and in low marshy grounds from Canada to

Minnesota and southward to Florida and Texas. It is propagated by its creeping rhizome, and is often found in large patches. The flowers appear about the end of May and the beginning of June, and the fruit ripens in the latter part of July. The leaves are said to be poisonous. The fruit has a subacid, sweetish, peculiar taste, agreeable to some palates, and may be eaten freely with impunity. From its color and shape, it is sometimes called *wild lemon.* The rhizome is said to be most efficient when collected after the falling of the leaves. It shrinks considerably in drying.

The commercial supplies of podophyllum are obtained chiefly from Virginia, Kentucky, North Carolina, Tennessee and Indiana. The dried rhizome is much wrinkled lengthwise, is yellowish or reddish-brown externally, and furnished with roots of a similar but somewhat paler color. It was determined, by an experiment of Wm. Saunders, that these roots contain as much active matter as the rhizome itself.

Description and Physical Properties.—"*Unground Podophyllum.*—Rhizome nearly cylindrical, jointed, compressed on the upper and lower surfaces, sometimes branched; in pieces usually less than 20 cm. in length, the internodes from 2 to 9 mm. in diameter, some of the nodes thickened; dark brown; longitudinally wrinkled or nearly smooth, with irregular, somewhat V-shaped scars of scale leaves; some of the nodes annulate, the upper portion with large, circular, depressed stem-scars and with buds or stem-bases; on the lower portion numerous root-scars or roots from 2 to 7 cm. in length and about 2 mm. in thickness; fracture short; internally the cork light brown, the wood portion a circle of small yellowish vascular bundles and the pith large and white; odor slight; taste disagreeably bitter and acrid.

"*Structure.*—An outer portion consisting of one or two layers of reddish-brown suberized cells; parenchyma of cortex and pith containing numerous starch grains, or occasional rosette aggregates of calcium oxalate; vascular bundles from 24 to 34, separated by rather wide medullary rays and each containing a few lignified tracheæ, a more or less distinct cambium and a rather large phloem.

"*Powdered Podophyllum.*—Light brown; starch grains numerous, spherical or polygonal, from 0.003 to 0.020 mm. in diameter, single or 2- to 6-compound; calcium oxalate rosette aggregates few, from 0.03 to 0.08 mm. in diameter; tracheæ with simple pores or reticulate thickenings; fragments of starch-bearing parenchyma and reddish-brown cork cells." *U. S.*

Assay.—"Proceed as directed under *Jalapa,* using 10 Gm. of Podophyllum in fine powder." *U. S.*

"Rhizome nearly cylindrical, of very variable length, usually about five millimetres thick; dark reddish-brown, smooth or only slightly wrinkled; enlarged at intervals of about five centimetres, the upper surface of each enlargement being marked by a depressed circular scar, below which, on the under surface, are rather stout, brittle, brown roots, or the scars corresponding to them. In transverse section, either nearly white and starchy, or pale yellowish-brown and horny. Characteristic odor; taste slightly bitter and acrid." *Br.*

The root in its aggregate state is nearly inodorous, but in powder has a sweetish not unpleasant odor. The taste is at first sweetish, afterwards bitter, nauseous, and slightly acrid.

Constituents.—The active ingredient of podophyllum is a neutral substance called *podophyllotoxin* and first isolated, in an impure condition, by Podwyssotzki in 1882.

Podophyllotoxin occurs in the form of crystalline prisms, strongly lævo-rotatory, with a melting point of 117° C. (the melting point of 94° often given for this compound is that of Kursten (*A. Pharm.,* 1891), but it is generally believed today that the substance he called podophyllotoxin was not the pure principle). When heated with alkalies it takes on a molecule of water and is converted into an inert, gelatinous substance, *podophyllic acid,* $C_{15}H_{16}O_7$. This latter may be dehydrated to yield *picropodophyllin* which is isomeric with *podophyllotoxin.* Picropodophyllin is optically inert and has a melting point of 227° C. See Dunstan and Henry (*A. J. P.,* 1898, 246). Podophyllotoxin and picropodophyllin furnish identical decomposition products; when oxidized with nitric acid, oxalic acid is the principal product; when fused with alkalies, *orcinol* and acetic acid are produced. Both substances contain three methyl groups and no hydroxyl. It is likely that picropodophyllin is the lactone of podophyllic acid. Picropodophyllin is therapeutically inactive.

In addition to podophyllotoxin there appears to be present an amorphous resinous substance, *podophyllo-resin,* which is also active. Podwyssotzki also obtained *podophylloquercetin,* the coloring principle, which is the cause of the varying color of resin of podophyllum. According to Dunstan and Henry it is identical with quercetin obtained from black oak bark.

Podophyllotoxin, $C_{23}H_{24}O_9$, is obtained by extracting the coarsely powdered rhizome with cold, light petroleum, until freed from fat; after drying in the air, the extraction is continued with chloroform, until the liquid comes away almost free from yellow color. As it is not possible to work with alcohol-free chloroform, too prolonged extraction with chloroform would yield a more impure extract. The chloroform extract is distilled and the residue is dried over a not too warm water bath, partially dissolved in benzene, filtered, and the filtrate allowed to remain from three to eight days, when a brownish-yellow mass of well-formed, thick, strongly refractive prisms is produced. This is purified by washing with a 50 per cent. alcohol, then with ether, recrystallizing first from boiling benzene, and finally from solution in hot 45 per cent. alcohol; the compound is thus obtained in long, well-formed prisms which melt at 94° C.

A commercial variety of podophyllotoxin is prepared by concentrating the chloroformic extract to a thick syrup and treating with alcohol-free ether as long as a precipitate is produced. The clear liquid is decanted and again concentrated and poured into petroleum ether. The resulting precipitate is dried and sold as *commercial podophyllotoxin.*

B. F. Carter (*A. J. P.,* 1886, p. 449) also examined the leaves. He found tannin, uncrystallized sugar, coloring matter, and 6 per cent. of resin. This latter seems to be of two-fold character, ether dissolving the soft resin, while the hard resin remains behind. The resin has a bitter taste and a much milder action than that of the rhizome. Fused with potassium hydroxide a small amount of protocatechuic acid seems to be formed.

An extract of podophyllum, when subjected to Bornträger's test for emodin-containing drugs, gives a bright yellow color with ammonia. This coloration is probably produced by the *quercetin.*

A fatty oil has been separated from the rhizome of podophyllum by Dohme and Engelhardt. (See *Proc. A. Ph. A.,* 1904, 340.)

Assay.—"Proceed as directed under Jalapa, using 10 Gm. of Podophyllum in fine powder." *U. S.*

A method of assay for podophyllum has been proposed by W. M. Jenkins (*J. I. and E. C.,* 1914, p. 671) which is based upon a shaking out method using a mixture of chloroform and alcohol.

Gordin and Merrell (*Proc. A. Ph. A.,* 1902, 343) propose to judge of the quality of resin of podophyllum by an assay based on the percentage of crude picropodophyllin and the following requirements: 1. Pure podophyllin must be completely soluble in about twice its weight of cold alcohol. 2. It should contain about 64 per cent. ether-soluble and about 74 per cent. chloroform-soluble matter. 3. It should yield about 22 per cent. crude picropodophyllin when assayed by the method described by them.

Uses.—Podophyllum is a slow but active and certain cathartic producing copious liquid discharges often with much griping. It has been attributed with cholagogic properties and is used in various forms of *hepatic torpor* but its virtues in this direction are probably no greater than that of other active purgatives. In small doses it is frequently used in *chronic constipation,* especially in conjunction with aloes or cascara.

In overdoses podophyllum acts as an irritant poison; an amount estimated at five grains of the resin caused death in a woman sixty years old (*N. Y. M. R.,* April, 1890); the symptoms were vomiting and purging, followed some hours after their cessation by coma, full soft pulse, slight elevation of temperature, and hemoglobinuria.

Dose, five to ten grains (0.32–0.65 Gm.), but it is rarely exhibited in the crude form.

POPULI GEMMÆ. N. F.

BALSAM POPLAR BUDS Popul. Gem. [Balm of Gilead Bud]

"Balsam Poplar Buds consists of the air-dried, closed, winter leaf-buds of *Populus nigra* Linné, *Populus candicans* Aiton, or *Populus balsamifera* Linné (Fam. *Salicaceæ*). Balsam Poplar Buds contains not more than 10 per cent. of flower buds and yields not more than 1 per cent. of acid-insoluble ash." *N. F.*

Balsam Poplar Buds; Balm of Gilead Buds; Gemma Populi; Oculi Populi; Peuplier Noir, Bourgeons de Peuplier, *Fr.;* Pappelknospen, *G.;* Yema de Alama Negro, *Sp.*

In most trees of the genus *Populus,* the leaf-buds are covered with a resinous exudation, which has a peculiar, agreeable, balsamic odor, and a bitter, balsamic, somewhat pungent taste. It is abundant in the buds of *Populus nigra* L., or the *black poplar* of Europe, which are official in some parts of that continent. They contain resin and a peculiar volatile oil. The buds of *P. balsamifera* L., the *Balsam Poplar* or *Tacamahac,* growing in the northern parts of North America and Siberia, are also highly balsamic; and a resin is said to be furnished by the tree. The buds are also obtained from *P. Candicans* Ait. which is the true Balm of Gilead.

Description and Physical Properties.—"Conical, pointed, up to 2 cm. in length and from 2 to 5 mm. in thickness, consisting of closely imbricated scales, externally brown and glossy, glutinous with fragrant resin; internally with abundant oleo-resin and numerous crystals of salicin. Odor pleasant, balsamic; taste aromatic and bitter." *N. F.*

The bark of *P. tremuloides* Michx., or *American aspen,* and of *P. tremula* L., or *European aspen,* contain *salicin* and another crystallizable principle named *populin,* $C_{20}H_{22}O_8 + 2H_2O$. The leaves of *P. tremula* are also said to yield more populin than does the bark. It is probable that both principles exist in the bark of *P. tremuloides* and other species. Schaak (*A. J. P.,* 1892, 226) found a bitter principle in the bark of *P. alba* L., which was most likely populin. Populin is very light and white, of a bitter, sweetish taste, analogous to that of licorice. It is soluble in 1896 parts of cold and about 70 parts of boiling water, and is more soluble in boiling alcohol. It loses its two molecules of water of crystallization at 100° C., and at 180° C. it fuses to a colorless liquid, from which at a higher temperature benzoic acid may be sublimed. Acetic acid and the diluted mineral acids dissolve it, and, upon the addition of an alkali, let it fall unchanged. Piria first showed it to be *benzoyl salicin,* $C_{13}H_{17}(C_7H_5O)O_7 + 2H_2O$. He then decomposed it and prepared salicin from it. Populin has been prepared synthetically by Dobbin and White (*P. J.,* 1904, lxxiii, p. 233) by the direct combination of salicin and benzoyl chloride. The leaf buds of the poplar contain besides the glucosides salicin and populin, an oleo-resin which yields a terpene, probably dipentene, to which its therapeutic use is to be attributed. The flower-buds of *P. tremuloides* yielded a bitter resin to R. Glenk. It was of yellowish-brown color, strong, hop-like odor, and had a melting point of 51° C. (*A. J. P.,* 1889, 240.)

Poplar buds are capable of imparting a principle to ointments which lessens their tendency to rancidity. The *unguentum populeum, Pommade de Bourgeons de Peuplier,* is made, according to the directions of the French Codex, from 100 Gm. each of the dried contused leaves of white poppy, belladonna, henbane, and black nightshade, and 800 Gm. of dried poplar buds. The leaves are moistened with 400 Gm. of alcohol and allowed to stand twenty-four hours in a closed vessel; 4000 Gm. of lard is now added and the mixture heated gently during three hours, stirring frequently, the crushed poplar buds are then added and allowed to digest for ten hours at a gentle heat, and the whole strained and cooled slowly. This is an anodyne ointment, employed in Europe in painful affections.

Uses.—The therapeutic action of poplar bud is analogous to that of the turpentines. It has been used externally as a mild counter-irritant in *muscular rheumatism.* Internally it is of value chiefly as a stimulating expectorant in subacute or chronic *bronchitis.* It is comparatively little employed except in combination with other drugs.

Dose, one drachm (4 Gm.).

Off. Prep.—Syrupus Pini Albæ Compositus, *N. F.;* Syrupus Pini Albæ Compositus cum Morphinæ, *N. F.*

POTASSA SULPHURATA. U. S., Br.

SULPHURATED POTASSA Pot. Sulphurat.

" Sulphurated Potassa is a mixture composed chiefly of potassium polysulphides and potassium thiosulphate and contains not less than 12.8 per cent. of sulphur (S) in combination as sulphide." *U. S.* " Sulphurated Potash is a mixture of salts of potassium, chiefly sulphides." *Br.*

Sulphurated Potash, *Br.;* Hepar Sulphuris; Potassii Sulphuretum, *U. S.* 1870; Sulphuret of Potassium, Sulphurated Potash; Potassium Sulphide; Crude Potassium Sulphide; Liver of Sulphur; Polysulfure de Potassium solide, Sulfure de Potasse, Foie de Soufre, *Fr.;* Kalium Sulfuratum, *P. G.;* Schwefelleber, Kalischwefelleber, *G.;* Sulfuro (tri) potasico hiposulfitado, Higado de Azufre, *Sp.*

" Potassium Carbonate, in powder, 100 *grammes;* Sublimed Sulphur, 50 *grammes.* Mix the Potassium Carbonate, previously dried, with the Sulphur; heat in a covered crucible, at first gently, afterwards to dull redness, until effervescence ceases and the mass fuses; pour it on to a clean stone slab, and, after solidification, break it into fragments and transfer to a stoppered bottle." *Br.*

The U. S. P. X gives no process; that of the U. S. P., 1890, is as follows: " Sublimed Sulphur, *one hundred grammes,* Potassium Carbonate, dried, *two hundred grammes.* Mix the powdered and dried Potassium Carbonate thoroughly with the Sublimed Sulphur, and gradually heat the mixture, in a covered crucible, which should be only about half filled with it, until the mass ceases to foam and is in a state of perfect fusion. Then pour the fused mass on a cold marble slab, and, after it has cooled, break it into pieces, and keep it in a well-stoppered bottle." *U. S.* 1890.

These processes are essentially the same, except that a greater heat is used in the British process, which somewhat modifies the result. When potassium carbonate is melted with half its weight of sulphur, the sulphur unites with the base, carbon dioxide being expelled. The composition of the resulting compounds of potassium and sulphur will vary with the heat employed. If the heat does not exceed 185° C., the resulting preparation will contain potassium trisulphide and thiosulphate; if above 300° C., potassium pentasulphide and sulphate. The reaction for the preparation at the lower temperature is

$$3K_2CO_3 + 4S_2 = 2K_2S_3 + K_2S_2O_3 + 3CO_2$$

which at the higher temperature is changed as follows:

$$4K_2S_2O_3 = 3K_2SO_4 + K_2S_5$$

The potassium pentasulphide formed is decomposed at this high temperature into sulphur, which burns off, and K_2S_3. The U. S. preparation, therefore, which was made at the temperature of fusion, contains potassium thiosulphate, and may be represented by the formula $2K_2S_3 + K_2S_2O_3$, three molecules of CO_2 escaping, while the British, being prepared at a red heat, contains potassium sulphate, the reaction probably being

$$4K_2CO_3 + 5S_2 = K_2SO_4 + 3K_2S_3 + 4CO_2$$

The present commercial article is probably intermediate between these two products, and contains less than 50 per cent. of sulphides calculated from the sulphur requirement of the rubric.

Description and Physical Properties.—Sulphurated potassa, when properly prepared, is a hard, brittle substance having a nauseous, alkaline, and bitter taste. Its color is liver-brown, and hence its name of *hepar sulphuris,* or *liver of sulphur.* The color of the surface of a fresh fracture is brownish-yellow. It is inodorous when dry, but emits a slightly fetid odor when moist, owing to the extrication of a little hydrogen sulphide gas. It is soluble in water, forming an orange-yellow liquid, and exhaling the odor of hydrogen sulphide.

"Irregular pieces, liver-brown, when freshly made, changing to a greenish-yellow and finally to gray through absorption of moisture, oxygen, and carbon dioxide. It has an odor of hydrogen sulphide and a bitter, acrid, and alkaline taste. Sulphurated Potassa is very soluble in water, usually leaving a slight residue. Alcohol dissolves only the sulphides.

"An aqueous solution of Sulphurated Potassa (1 in 10) is light brown in color and is strongly alkaline to litmus paper. The addition of an excess of acetic acid to this solution causes a brisk evolution of hydrogen sulphide and a precipitation of sulphur. In the liquid thus treated, after filtration, an excess of sodium bitartrate T.S. produces within fifteen minutes an abundant, white, crystalline precipitate.

"Preserve in well-closed containers." *U. S.*

"Solid fragments, externally greenish-yellow, internally pale liver-brown, rapidly changing to greenish-yellow on exposure to the air. Odor that of hydrogen sulphide; taste alkaline and acrid. Readily soluble in *water.* Aqueous solution yellowish, opalescent; deposits only a trace of sediment on standing; evolves hydrogen sulphide freely on the addition of excess of *hydrochloric acid,* sulphur being deposited; this acid liquid, boiled and filtered, gives a yellow precipitate with *solution of platinic chloride.* Sulphurated Potash contains not less than 42 and not more than 45 per cent. of sulphur as determined by the following process:—Dissolve 0.2 gramme in 10 millilitres of *water* in a small flask, add 5 millilitres of *solution of sodium hydroxide,* heat the liquid to boiling, and add slowly, the flask being constantly rotated, *solution of bromine As T.* until a clear solution is obtained and bromine is present in excess. Acidify with *hydrochloric acid,* boil until the excess of bromine is driven off, add excess of *solution of barium chloride,* collect the precipitate formed, wash, dry, ignite, and weigh. It weighs not less than 0.611 or more than 0.655 grammes." *Br.*

By exposure to the air it attracts oxygen, and the potassium sulphide is gradually changed into potassium sulphate, when the preparation becomes inodorous, and white on the surface. When boiled with an excess of hydrochloric acid and filtered, it gives a yellow precipitate with platinic chloride, and a white one with barium chloride. The preparation of the Br. Pharmacopœia yields about one-half of its weight to alcohol (90 per cent.)—the portion dissolved being potassium sulphide, and the undissolved portion potassium sulphate.

Assay.—"Dissolve 1 Gm. of crystallized copper sulphate, accurately weighed, in 15 cc. of distilled water and 1 Gm. of Sulphurated Potassa, accurately weighed, in 10 cc. of distilled water, in a flask. Add the copper sulphate solution to the Sulphurated Potassa solution in a stoppered bottle, stopper, shake for a few minutes, and filter. Acidulate the filtrate with acetic acid, refilter if necessary, and add an equal volume of hydrogen sulphide T.S. No black precipitate is produced." *U. S.*

This compound has been used as an ingredient in the preparation known as *Lotio Sulphurata* (also called *Lotio alba* but not the same as the *Lotio alba Veterinaria* N. F.). The following formula for this is given by Raubenheimer (*J. A. Ph. A.,* 1914, 692): Zinc sulphate, 5 Gm.; sulphurated potassa, 5 Gm.; distilled water, q.s. to make 125 cc. Dissolve each chemical in 60 cc. of distilled water; filter the solutions separately and mix by slowly pouring the potassa solution into the zinc solution, then add sufficient distilled water to make 125 cc. Rose water may be used in place of distilled water. It is essential that the sulphurated potassa be fresh and free from iron compounds, as has been pointed out by J. C. and B. L. DeG. Peacock, *Proc. P. P. A.,* 1914, 256.

Uses.—Internally sulphurated potassa was formerly employed in *chronic rheumatism, skin diseases, asthma,* etc., but is to-day rarely used as an internal remedy. While if given in sufficient dose it may exercise the same effects upon the system as sulphur it is much more irritant to the stomach and has no advantages. It is, however, a valuable external agent in the treatment of various skin diseases. The alkaline sulphides exercise a solvent action upon the horny element of the skin and therefore sulphurated potassa is useful in *psoriasis* and other conditions in which there is excessive formation of scales. Because of the anti-parasitic action of the hydrogen sulphide which it liberates on contact with the skin, it is one of our most valuable remedies in the treatment of *scabies, ring-worm, tinea versicolor,* and other parasitic diseases. In *acne rosaceæ* and other skin diseases with sluggish circulation its local stimulating action tends to restore tone to the dilated blood vessel. It may be used either as a lotion, an ointment, or bath. As a lotion it is usually used in strengths of about 5 per cent. but in sluggish conditions may be employed up to 10 per cent. For an ointment one-half a drachm of sulphurated potassa (2 Gm.) may be rubbed up with one-half an ounce (15 Gm.) of lard. For a bath about one-half a drachm is employed for each gallon of water. The odor of sulphurated potassa is favorably modified whether in solution or ointment, by incorporating with it a little oil of anise.

The solution of sulphurated potassa is decomposed by the mineral acids, which liberate hydrogen sulphide and precipitate the excess of sulphur. It is also incompatible with solutions of most of the metals, which are precipitated as sulphides.

Dose, from two to ten grains (0.13–0.65 Gm.).

POTASSII ACETAS. U. S., Br.

POTASSIUM ACETATE Pot. Acet.

"Potassium Acetate, when dried to constant weight at 150° C., contains not less than 99 per cent. of $KC_2H_3O_2$." *U. S.* "Potassium Acetate may be obtained by fusing the product of the interaction of acetic acid and potassium carbonate. It contains not less than 90 per cent. of pure potassium acetate, $KC_2H_3O_2$." *Br.*

Kali Aceticum, Sal Diureticum, Acetas Potassicus, s. Kalicus, Terra Foliata Tartari; Acetate of Potassium; Diuretic Salt; Kalium Aceticum, *Fr. Cod.;* Acetate de Potasse sec, Terre Foliée de Tartre, *Fr.;* Essigsaures Kali, *G.;* Acetato di potassio, *It.;* Acetato potasico, *Sp.*

As this salt is practically never prepared on a small scale, no process is given in either of the Pharmacopœias. It may be prepared by the interaction between potassium carbonate and acetic acid. It is best to have the solution always slightly acid, for if the alkali predominate, it will react upon the acetic acid when the solution is concentrated, and give rise to discoloration. On account of the liability of discoloration, great care must be observed to avoid the contamination of iron. Some manufacturers use silver dishes.

Description and Physical Properties.—" A white powder, or crystalline flakes, or masses of satin-like luster. It is odorless or has a faint, acetous odor, and a warming saline taste. It is very deliquescent on exposure to the air. One Gm. of Potassium Acetate is soluble in 0.5 cc. of water and in 2.9 cc. of alcohol, at 25° C. One Gm. is soluble in about 0.2 cc. of boiling water.

" When slightly heated, the salt fuses. On strong ignition it is decomposed with the evolution of inflammable empyreumatic vapors and leaves a black residue of potassium carbonate and carbon. This residue imparts to a non-luminous flame a violet color, is alkaline to litmus paper, and effervesces with acids. An aqueous solution of Potassium Acetate (1 in 10) responds to the reactions for potassium, and for acetates.

" An aqueous solution of the salt (1 in 20) is alkaline to litmus paper but does not affect phenolphthalein T.S. An aqueous solution of the salt meets the requirements of the test for *heavy metals.* An aqueous solution of the salt meets the requirements of the test for *arsenic.*

" **Assay.**—Dry the salt to constant weight at 150° C. and proceed as directed under the assay for alkali salts of organic acids. Each cc. of half-normal sulphuric acid corresponds to 0.04907 Gm. of $KC_2H_3O_2$.

" Preserve in air-tight containers." *U. S.*

" White foliaceous satiny masses, or in granules. Taste sharp, saline. Very deliquescent. Soluble in 0.5 part of *water,* and in 2 parts of *alcohol* (90 per cent.). Aqueous solution alkaline to *litmus.* Yields the *reactions* characteristic of potassium and of acetates. Yields no characteristic *reactions* for copper, iron, aluminum, calcium, magnesium, carbonates, or sulphides, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million. Loses not more than 10 per cent. of its weight when dried at 100° C. One gramme, heated to redness until gases cease to be evolved, leaves an alkaline residue which, when treated with *water,* filtered, and well washed, yields a clear solution requiring for neutralisation not less than 18.3 millilitres of *N/2 solution of sulphuric acid." Br.*

Potassium acetate is incompatible with the mineral acids; with sodium and magnesium sulphates; with corrosive sublimate and silver nitrate, and with several other earthy and metallic salts.

Uses.—The effects of potassium acetate upon the system are very similar to those of the citrate (see *Potassii Citras*), except that it is less likely to act upon the bowels. Like the citrate it is oxidized in the system and appears in the urine as a carbonate and therefore tends to render this secretion alkaline. It is usually less acceptable to the palate than the citrate. It is especially employed in the treatment of *rheumatic fever* and the *uric acid diatheses.* It is also sometimes used for its diuretic effect in *dropsies* and *nephritis.* J. A. Easton, of Glasgow, has found it useful in several skin diseases, such as *psoriasis* and *eczema.*

Dose, fifteen to sixty grains (1–3.9 Gm.).

Off. Prep.—Elixir Buchu et Potasii Acetatis, *N. F.;* Elixir Buchu, Juniperi et Potassii Acetatis, *N. F.*

POTASSII BICARBONAS. U. S., Br.

POTASSIUM BICARBONATE Pot. Bicarb.

" Potassium Bicarbonate, when dried to constant weight over sulphuric acid, contains not less than 99 per cent. of $KHCO_3$." *U. S.* " Potassium Bicarbonate may be obtained by saturating a strong aqueous solution of potassium carbonate with carbon dioxide. It contains not less than 99 per cent. of pure potassium bicarbonate, $KHCO_3$." *Br.*

Bicarbonas Potassicus, s. Kalicus; Bicarbonas Monopotassicus; Potassium Hydrogen Carbonate; Acid Carbonate of Potassium; Bicarbonate of Potash; Potash Saleratus; Kalium Bicarbonicum, *Fr. Cod.;* Carbonate de Potasse Acide; Bicarbonate de Potasse, *Fr.;* Kalium Bicarbonicum, *P. G.;* Kalium-bicarbonat, Doppelt-Kohlensaures Kali, *G.;* Bicarbonato di potassio, *It.;* Bicarbonato potasico, *Sp.*

The process of the U. S. P. 1870, and also that of the British Pharmacopœia for this salt were abandoned at former revisions.

The reaction by which it is produced from potassium carbonate by the action of carbon dioxide is as follows:

$$K_2CO_3 + H_2O + CO_2 = 2KHCO_3$$

It was formerly made by numerous processes some of which being more or less empirical—such as one in which the waste CO_2 of breweries was allowed to act upon a concentrated solution of potassium carbonate—produced salts of indefinite composition. Much of the *potash saleratus* used, for leavening purposes in culinary operations, was in reality a sesquicarbonate, which is intermediate between a carbonate and a bicarbonate. The principle of the modern large scale process is the passing of carbon dioxide gas into a solution of potassium carbonate.

Description and Physical Properties.—"Colorless, transparent, monoclinic prisms or a white, granular powder. It is odorless, and has a saline and slightly alkaline taste. It is stable in the air. One Gm. of Potassium Bicarbonate is soluble in 2.8 cc. of water at 25° C. One Gm. is soluble also in 2 cc. of water at 50° C. It is almost insoluble in alcohol. When heated above 50° C., an aqueous solution of the salt loses carbon dioxide and water, and at boiling heat the salt is almost completely converted into normal carbonate. The dry salt begins to lose carbon dioxide and water at 100° C., this loss increasing at a higher temperature until at a red heat there remains a residue of carbonate, which imparts a violet color to a non-luminous flame.

"An aqueous solution of Potassium Bicarbonate (1 in 10) is slightly alkaline to litmus paper, but is neutral or very slightly alkaline to phenolphthalein T.S. An aqueous solution of Potassium Bicarbonate (1 in 10) responds to the reactions for potassium, and for carbonates.

"Add 2 cc. of tenth-normal hydrochloric acid and 2 drops of phenolphthalein T.S. to 1 Gm. of the salt, dissolved without agitation in 20 cc. of distilled water at a temperature not above 15° C.: a red tint does not appear immediately (*carbonate*). An aqueous solution of the salt (1 in 50), mixed with a slight excess of hydrochloric acid, meets the requirements of the test for *heavy metals*.

"Preserve in well-closed containers." *U. S.*

"Colorless, monoclinic, non-deliquescent prisms. Taste saline, feebly alkaline. Soluble in 4 parts of *water*, almost insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium and of bicarbonates. 1 gramme exposed to a low red heat leaves not less than 0.683 or more than 0.690 gramme of a white residue, which requires for neutralisation not less than 19.8 or more than 20 millilitres of *N/2 solution of sulphuric acid.* Yields no characteristic *reactions* for copper, sulphates, or sodium, and not more than the slightest *reactions* for iron or chlorides. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million. 20 grammes of Potassium Bicarbonate are neutralised by 14 grammes of Citric Acid, and by 15 grammes of Tartaric Acid." *Br.*

Assay.—"Dry about 4 Gm. of Potassium Bicarbonate to constant weight over sulphuric acid, weigh accurately, dissolve it in 25 cc. of distilled water, and titrate with normal sulphuric acid, methyl orange T.S. being used as indicator. Each cc. of normal sulphuric acid corresponds to 0.1001 Gm. of $KHCO_3$." *U. S.*

When heated to redness it loses carbon dioxide and returns to the state of carbonate, which, when thus obtained, is free from silica, and otherwise very pure. This method was adopted in the U. S. Pharmacopœia of 1870 for obtaining the pure carbonate. Potassium bicarbonate does not decompose calomel. When dissolved in 40 parts of water, it produces merely a white haze with a solution of corrosive sublimate; but if it contain so much as a hundredth part of carbonate, a brick-red precipitate is immediately produced. (Christison.)

Uses.—Potassium bicarbonate is comparatively little employed in medicine. It has approximately an equal neutralizing power weight for weight with bicarbonate of soda, and has the added advantage of being much more easily soluble in water. It should therefore be a valuable antacid in cases of *gastric hyperacidity,* but for some reason or other is comparatively rarely prescribed. As a systemic alkalizer it is inferior to the sodium salts because of the toxic effect of large doses of potassium.

Dose, ten to thirty grains (0.65–2 Gm.).

POTASSII BICHROMAS. Br.

POTASSIUM BICHROMATE

"Potassium Bichromate may be obtained by roasting chrome ironstone with lime in the presence of air, and treating the resulting chromate with a potassium salt, and subsequently with an acid. It contains not less than 99 per cent. of pure potassium bichromate, $K_2Cr_2O_7$." *Br.*

Potassii Dichromas, *U. S.* 1890; Potassium Dichromate, Red Chromate of Potash (Potassa), Bichromate of Potash; Kali Bichromicum, Kali Chromicum Rubrum; Dichromas Kalicus; Chromate Acide de Potasse, *Fr.;* Bichromate de Potasse, *Fr.;* Kalium dichromicum, *P. G.;* Kaliumdichromat, Zweifach Chromsaures Kali, Doppeltchromsaures Kali, *G.;* Bicromato di potassio, *It.;* Bicromato potasico, *Sp.*

Potassium dichromate was deleted from the U. S. P. IX list, but will be found among the reagents under *Potassium Dichromate, Purified.* (See Part III.)

This salt is most conveniently prepared from the neutral or yellow *potassium chromate,* by acidulating its solution with sulphuric acid and setting it aside for a day or two. In the action which follows we may suppose two reactions take place:

$$2K_2CrO_4 + H_2SO_4 = K_2SO_4 + 2KHCrO_4$$
$$2KHCrO_4 = K_2Cr_2O_7 + H_2O$$

As chromium is mainly found in nature as chrome iron ore, $FeO.Cr_2O_3$ or *chromite,* the salts of the element are usually made from this product. The yellow chromate is obtained from chrome iron ore by heating with potassium nitrate, and lixiviating the resulting mass with water, or it may be produced by heating the chrome iron ore in a reverberatory furnace with access of air in the presence of potassium carbonate and lime. This reaction is as follows:

$$2FeOCr_2O_3 + 4K_2CO_3 + 4CaO + 7O = Fe_2O_3 + 4CaCO_3 + 4K_2CrO_4$$

In another process the chrome iron ore is melted in a reverberatory furnace with soda and lime in the presence of air. The reaction is as follows:

$$2Cr_2O_4Fe + 4Na_2CO_3 + 4CaO + 7O = Fe_2O_3 + 4CaCO_3 + 4Na_2CrO_4$$

The manufacture of potassium dichromate is almost entirely an English monopoly at present, although some is manufactured in America from California ore. The solution, by evaporation, yields the yellow salt in crystals.

"In orange-red crystals. Soluble in 10 parts of *water.* Aqueous solution acid to *litmus;* gives a yellowish-white precipitate with *solution of barium chloride;* acquires an emerald-green color when warmed with *sulphuric acid* and *alcohol* (90 per cent.). When 0.1 gramme is dissolved in 20 millilitres of *water* acidified with 5 millilitres of *diluted sulphuric acid,* and then 2 grammes of *potassium iodide* added, the solution thus obtained, diluted with *water,* requires for decolorisation not less than 20.1 millilitres of *N/10 solution of sodium thiosulphate* (presence of not less than 99 per cent. of pure potassium bichromate, $K_2Cr_2O_7$)." *Br.*

The oxidizing action of potassium dichromate which is so especially marked in the presence of free sulphuric acid may be understood by the following reaction in which it will be seen that each molecule of the dichromate yields 3 atoms of nascent oxygen and a molecule of chrome alum.

$$K_2Cr_2O_7 + 4H_2SO_4 = 4H_2O + Cr_2(SO_4)_3.K_2SO_4 + 3O$$

Uses.—Potassium dichromate is an irritant caustic acting much like chromium trioxide (*q. v.*) It was used by Robin, in 1850, in the treatment of *syphilis,* but was entirely abandoned to be later revived by Helbig. (*Aerzt. Runds.,* 1910, p. 157.) He administers one-sixth of a grain (0.01 Gm.) well diluted three times a day. Fenwick (*B. M. J.,* 1909) recommends in *cancer* the injection of eight to fifteen minims (0.5–0.9 cc.) of a 10 per cent. solution into the tumor, and Gemmil (*B. M. J.,* 1909) has had good results from its local application in *rodent ulcer.*

In overdose it operates as a violent irritative and corrosive poison, producing severe vomiting, frequent dark hemorrhagic dejections, violent abdominal pains, pronounced disturbances of the circulation, coma, heart failure, collapse, etc. Less than an ounce has caused unconsciousness in five minutes, with death thirty-five minutes later. (*B. M. J.,* ii, 1888.) The antidote is a non-irritant alkali, such as sodium carbonate, soap or magnesia.

Potassium dichromate is used largely in calico printing and for other technical purposes. The workmen engaged in making it are liable to painful ulcerations of the hands, and, in consequence of the acrid vapors evolved, violent irritation of the nostrils is apt to be experienced, with severe pricking sensations and excessive sneezing, followed in time by destruction of the mucous membrane and even of the septum itself. It is asserted that this result may be avoided by breathing through the mouth exclusively, the profuse secretion of saliva produced carrying off the poisonous particles. (*B. F. M. R.,* Oct., 1863.)

Mueller's Fluid is used for preserving anatomical specimens. It consists of from 2 to 2.5 parts of potassium dichromate, 1 part of sodium sulphate, and 100 parts of water.

Dose, one-tenth to one-fifth of a grain (0.006–0.012 Gm.).

POTASSII BITARTRAS. U. S. (Br.)

POTASSIUM BITARTRATE Pot. Bitart. [Cream of Tartar, Potassium Acid Tartrate]

"Potassium Bitartrate, when dried to constant weight at 100° C., contains not less than 99.5 per cent of $KHC_4H_4O_6$." *U. S.* "Acid Potassium Tartrate may be obtained from the crude cream of tartar deposited during the fermentation of grape juice. It contains not less than 99 per cent. of pure potassium hydrogen tartrate, $KHC_4H_4O_6$." *Br.*

Potassii Tartras Acidus, *Br.;* Acid Potassium Tartrate Crystals of Tartar; Purified Cream of Tartar; Tartrate Acide de Potasse, Bitartrate de Potasse, Crème de Tartre, Pierre de Vin, *Fr.;* Kalium Bitartaricum, *Fr. Cod.;* Tartarus depuratus, *P. G.;* Weinstein, Kali Bitartaricum, Kalium Hydrotartaricum, Bitartras Potassicus, s. Kalicus, Cremor Tartari, *G.;* Tartrato acido di potassio, Cremor di tartaro, *It.;* Tartrato bi potasico, Cremor de tartaro, *Sp.*

During the fermentation of wines, especially those that are tart, a peculiar matter is deposited in the casks, forming a crystalline crust, called *crude tartar,* or *argol.* That deposited from red wines is of a reddish color, and called *red tartar,* while that derived from white wines is of a dirty-white color, and denominated *white tartar.* Both kinds consist of crude potassium bitartrate, or *cream of tartar* as it is commonly called. The deposition of the tartar is thus explained: The acid tartrate exists naturally in the juice of the grape, held in solution by saccharine matter. When the juice is submitted to fermentation in the process for converting it into wine, the sugar disappears, and is gradually replaced by alcohol, in which the salt is insoluble. It is from argol that acid potassium tartrate is obtained by a process of purification.

The process for purifying argol is very simple and is based upon the great difference in the solubility of the salt in hot and cold water. Simple solution, filtration, clarification if necessary, and crystallization yield an article which is of an exceedingly high degree of purity.

Description and Physical Properties.—"Colorless or slightly opaque, rhombic crystals, or a white, somewhat gritty powder. It is odorless, and has a pleasant acidulous taste. It is stable in the air. One Gm. of Potassium Bitartrate is soluble in 155 cc. of water and in 8820 cc. of alcohol, at 25° C. One Gm. is soluble in 16 cc. of boiling water.

"A saturated aqueous solution of the salt is acid to litmus paper. When Potassium Bitartrate is heated, it chars and emits inflammable vapors, having the odor of burning sugar. At a higher temperature and with free access of air, the carbon of the black residue is consumed, and a white, fused mass of potassium carbonate remains, which has an alkaline reaction, effervesces with acids, and colors a non-luminous flame violet. A saturated aqueous solution of

Potassium Bitartrate yields with sodium cobaltic nitrite T.S. a yellow precipitate.

"Neutralize a saturated aqueous solution of the salt with sodium hydroxide T.S. in a test tube, add silver nitrate T.S., then just sufficient ammonia T.S. to dissolve the white precipitate, and boil the solution; silver is deposited on the inner surface of the test tube, forming a mirror.

"When 0.5 Gm. of the salt is dissolved in 3 cc. of ammonia T.S., no insoluble residue remains (*starch, kaolin, calcium phosphate, or other insoluble matter*). A 10 cc. portion of an aqueous solution of the salt (1 in 50), made with the aid of just sufficient hydrochloric acid, meets the requirements of the test for *heavy metals.* Ammonia is not evolved on heating the salt with a slight excess of sodium hydroxide T.S. Mix 1 Gm. of Potassium Bitartrate in a platinum or silica crucible with 0.5 cc. of sulphuric acid and 1 cc. of nitric acid, and heat the mixture until fumes of sulphur trioxide begin to be liberated. Cool the resulting mass, treat it with 10 cc. of distilled water, and filter: the filtrate, made slightly alkaline with sodium hydroxide T.S., does not yield a gelatinous precipitate soluble in excess of the reagent (*alum*). Heat 10 Gm. of Potassium Bitartrate with 15 cc. of distilled water, add hydrochloric acid until the salt is dissolved, then add 2 cc. of sulphurous acid, and boil the mixture until the odor of sulphur dioxide is barely perceptible. Cool the solution, mix it with 1 cc. of sodium cyanide T.S., and follow this immediately with stronger ammonia water until the precipitate first formed is redissolved and the solution has a slight odor of ammonia. When cold, transfer the solution to a 50 cc. graduated, glass-stoppered cylinder, dilute it with sufficient distilled water to measure 50 cc., and add 3 drops of sodium sulphide T.S. After thorough mixing, the color produced in the solution, if any, when viewed downward against a white surface, is not greater than the color of a control solution prepared as follows: Dissolve 2 Gm. of reagent ammonium chloride in 20 cc. of distilled water, add 4 cc. of a solution containing 0.08 Gm. of lead nitrate in 1000 cc. of distilled water, and then 1 cc. of diluted hydrochloric acid. Treat this solution with the same quantities of hydrochloric acid, sulphurous acid, sodium cyanide T.S., and stronger ammonia water, as used above. Transfer it to another 50 cc. glass-stoppered cylinder, then dilute with sufficient distilled water to make 50 cc., and add 3 drops of sodium sulphide T.S. Before adding the sodium sulphide T.S. the liquid must possess a distinct odor of ammonia and the two cylinders used must be matched, be of practically colorless glass, and have the same internal diameter (*lead*).

"**Assay.**—Dry about 6 Gm. of Potassium Bitartrate to constant weight at 100° C., weigh accurately, dissolve in 100 cc. of boiling distilled water, and titrate with normal sodium hydroxide, using phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.1882 Gm. of $KHC_4H_4O_6$.

"Preserve in well-closed containers." *U. S.*

"A gritty white powder, or fragments of crystalline cakes. Taste acid. Soluble in 220 parts of *water;* insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium and of tartrates. 1 gramme requires for neutralisation not less than 10.5 millilitres of *N/2 solution of sodium hydroxide.* Yields no characteristic *reactions* for copper, or iron, and not more than the slightest *reactions* for calcium, magnesium, sodium, chlorides, or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 2 parts per million." *Br.*

With salifiable bases which form soluble tartrates, it gives rise to double salts, consisting of neutral potassium tartrate, and the tartrate of the base added. Several of these are important medicines. Cream of tartar, though sparingly soluble in water, becomes abundantly so by the addition of borax or boric acid. *Soluble Cream of Tartar* (*Potassium Borotartrate, Tartarus boraxatus, Kali tartaricum boraxatum, Cremor tartari solubilis.*) Borax, 2 parts; distilled water, 20 parts. Dissolve, and add 5 parts purified cream of tartar. Agitate to dissolve, filter, evaporate to dryness, and powder. Soluble cream of tartar may be made by substituting boric acid for the borax. *Boric acid soluble cream of tartar* may be made by the following formula. Four hundred parts of cream of tartar and 100 of the acid are dissolved in a silver basin, at the boiling temperature, in 2400 parts of water. The solution is kept boiling until the greater part of the water is consumed. The fire is then moderated, and the solution continually stirred while the evaporation proceeds. When the matter has become very thick, it is removed by portions, which are flattened in the hand, completely dried by the heat of a stove, powdered, and kept in well-stoppered bottles. This form of soluble cream of tartar is more soluble than that made with borax. The product should not be powdered, but kept in large grains.

The cream of tartar of commerce is now nearly pure potassium bitartrate. It has been, however, found purposely mixed with various substances, such as sand, clay, gypsum, flour, chalk, alum, and potassium sulphate. These are excluded by the official tests except the last which may be recognized by its causing a precipitate with barium chloride, not entirely soluble in nitric acid. The action of the last-mentioned test is explained by the fact that the barium tartrate is soluble and the sulphate insoluble in nitric acid. The U. S. Pharmacopœia requires that it should contain 99.5 per cent. of pure potassium bitartrate, and there is no difficulty in obtaining it in commerce of this quality. Coupland gives in *P. J.*, 1901, 282, the results of an examination of commercial cream of tartar as follows: While in 1884 the assays of cream of tartar revealed from 8 to 14 per cent. of calcium tartrate, the quality has continuously improved and it contained, in 1901, 4.6 per cent. But cream of tartar of greater purity is by no means an exceptional article, potassium bitartrate of a quality of 98 and 99 per cent. being common, the latter coming from America. The competition among makers of "baking powders," into which it enters, explains in part the improvement in the quality of cream of tartar.

Uses.—The tartrates differ from the salts of most of the other vegetable acids in that they are not oxidized in the body but are eliminated unchanged through the kidney. It follows that they do not act as systemic alkalizers as do the citrates and acetates. The tartrates are also less readily absorbed from the intestines than the citrates, and therefore more prone to exercise a laxative effect. Potassium bitartrate when given in full dose has a mild saline cathartic action and is much used for this purpose, especially in combination with other laxatives. In smaller dose it may be absorbed from the alimentary canal and act as a diuretic. Some believe that its stimulating influence upon the kidney is more pronounced than that of the citrates, but it is probable that the only difference in their diuretic effect depends upon the antacid action of the citrate. Potassium bitartrate was formerly a favorite remedy in the treatment of *dropsies,* especially in conjunction with juniper, but we believe is less frequently employed at the present. Its solution in boiling water, sweetened with sugar and allowed to cool, forms an acid, not unpleasant, refrigerant drink, advantageously used in some *febrile affections,* and frequently employed as a domestic remedy. The beverage called *imperial* (*potus imperialis*) is a drink of this kind, made by dissolving half an ounce of the salt in three pints of boiling water, and adding to the solution four ounces of white sugar and half an ounce of fresh lemon peel.

As a diuretic, cream of tartar may be administered in the dose of a drachm and a half or two drachms (5.8–7.7 Gm.) several times a day. In pharmacy, cream of tartar is employed to obtain the neutral potassium tartrate (soluble tartar), potassium and sodium tartrate (Rochelle salt), antimony and potassium tartrate (tartar emetic), and iron and potassium tartrate (tartarized iron). Deflagrated with potassium nitrate, or incinerated alone, it is converted into a pure form of potassium carbonate, called salt of tartar.

Dose, as a diuretic, fifteen to forty-five grains (1–3 Gm.); as a cathartic, two to six drachms (8–23 Gm.).

POTASSII BROMIDUM. U. S., Br.

POTASSIUM BROMIDE Pot. Brom.

"Potassium Bromide, when dried to constant weight at 100° C., contains not less than 98.5 per cent. of KBr." *U. S.* "Potassium Bromide may be obtained by the interaction of ferrous bromide with potassium carbonate. When dried at 100° it contains not less than 98 per cent. of pure potassium bromide, KBr." *Br.*

Bromide of Potassium; Bromuretum Potassicum, s. Kalicum; Bromure de Potassium, *Fr.;* Kalium bromatum, *P. G.;* Bromkalium, Kaliumbromid, *G.;* Bromuro di potassio, *It.;* Bromuro potasico. *Sp.*

No process is given in recent Pharmacopœias but in the 1870 U. S. P. a solution of ferrous bromide was formed by the reaction between iron wire and bromine in boiling water and this, by the addition of the solution of potassium carbonate, was decomposed so as to produce ferrous carbonate, which precipitated, while potassium bromide remained in solution. By straining, the precipitated carbonate was separated, and from the strained liquor potassium bromide was obtained by evaporation and crystallization. In the process of the Br., 1885, by reaction between potassium hydroxide and bromine, the potassium bromide and bromate are produced in solution; these having been evaporated to dryness are mixed with charcoal and exposed to a red heat, whereby the potassium bromate is converted into potassium bromide. The solution of potassium bromide is then allowed to crystallize as in the preceding method. In either method the final crystallization takes place from a slightly alkaline solution in order to yield a more stable salt.

Description and Physical Properties.—"Colorless or white, odorless cubical crystals or a granular powder. It is stable in the air. One Gm. of Potassium Bromide is soluble in 1.5 cc. of water, in about 250 cc. of alcohol, and in 4.6 cc. of glycerin, at 25° C. One Gm. is soluble in 1 cc. of boiling water and in about 21 cc. of boiling alcohol. An aqueous solution of Potassium Bromide (1 in 20) is neutral or faintly alkaline to litmus paper. When the salt is heated upon platinum foil, it decrepitates; upon further heating (about 750° C.) it fuses without decomposition and at higher temperatures, it volatilizes, imparting a violet color to a non-luminous flame.

"An aqueous solution of the salt (1 in 5) responds to the reactions for potassium, and for bromides.

"Dissolve 1 Gm. of Potassium Bromide in 10 cc. of distilled water and add 0.1 cc. of tenth-normal sulphuric acid: no color is produced by the subsequent addition of a drop of phenolphthalein T.S. even after heating (*alkali*). Add a few drops of ferric chloride T.S. to 10 cc. of an aqueous solution of the salt (1 in 20), shake the mixture, and add 1 cc. of chloroform: the latter does not acquire a violet tint (*iodide*). Drop 1 cc. of diluted sulphuric acid upon about 1 Gm. of the powdered salt: no yellow color appears at once (*bromate*). A 10 cc. portion of an aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, is not immediately rendered turbid by the addition of 1 cc. of potassium sulphate T.S. (*barium*). A solution of 2 Gm. of Potassium Bromide in 50 cc. of distilled water shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid. An aqueous solution of the salt meets the requirements of the test for *heavy metals*.

"**Assay.**—Dry the salt to constant weight at 100° C., and proceed as directed under the assay for bromides. Each cc. of tenth-normal silver nitrate corresponds to 0.01190 Gm. of KBr. Each Gm. of Potassium Bromide, previously dried, corresponds to not less than 82.8 cc. and not more than 84.8 cc. tenth-normal silver nitrate.

"Preserve in well-closed containers." *U. S.*

"Colorless cubical crystals. No odor; taste pungent and saline. Soluble in 2 parts of *water*, and in 200 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium and of bromides. Loses not more than 1 per cent. of its weight when dried at 100° C.; 0.5 gramme of this dried salt requires for complete precipitation not less than 41.2 or more than 42.5 millilitres of *N/10 solution of silver nitrate*. Yields no characteristic *reactions* for copper, iron, barium, calcium, magnesium, carbonates, bromates, or iodates, and not more than the slightest *reactions* for iodides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

According to Chas. D. Chase, the commercial salt often is too alkaline, and will precipitate the alkaloids from the solution of their salts; as some of the alkaloids are precipitated even by neutral bromides, pharmacists usually apply a "shake well" label to such prescriptions as contain combinations of the bromides and alkaloidal salts.

Uses.—The effects of potassium bromide on the system are due chiefly to the bromine ion, although under certain conditions they may be more or less modified by the potassium. The bromides in sufficient concentration are depressants apparently to all forms of nervous tissue but show a marked selective action for certain centers. In the frog the most susceptible part is the sensory side of the spinal cord and it is possible in these animals to produce a condition of almost complete anesthesia and loss of reflex activity, with the voluntary motion well preserved. In man, however, the first effect seems to be upon the motor area of the brain and while these centers are not completely paralyzed there is a great reduction in the irritability of the psychomotor tract from doses insufficient to cause any marked diminution of the reflexes or distinct loss of sensation. With sufficient doses, however, both of these evidences of depression of the sensory cells of the cord may be apparent even in human beings. While after toxic quantities or in certain specially susceptible individuals there may be marked disturbances of intellection, this psychical depression is usually a late phenomenon. As far as the circulatory apparatus and other vital functions are concerned the bromides are practically inert. The old belief that the bromides were depressant to the heart was based upon experiments made with the potassium salt and it has been shown by Greene and Kruse (*J. A. M. A.*, 1913, lxi, p. 271) that the depressant action of this salt is due to its potassium rather than to its bromine. When used continuously over long periods of time the bromides exert a profound influence upon the nutritive processes which, however, is not clearly understood. Schultz (*Z. B.*, 1883, xix, p. 301) has found an increase in the quantity of nitrogen eliminated but a diminution in the output of phosphorus.

As the drug is eliminated very slowly, when used continuously it tends to accumulate in the system and in sufficient dose may give rise to the phenomena known as *bromism*. The first symptom is usually an eruption on the skin of acne or furuncles, often associated with fetor of the breath. After more severe poisoning there may occur muscular weakness, general mental and bodily sluggishness, loss of memory, often marked sleepiness, depression of spirits deepening into complete apathy, lowering of temperature, and finally a universal depression of function, the patient lying in bed scarcely more than a feeble automaton. A remarkable thing about bromism is the rapidity and completeness with which the symptoms clear up on ceasing the use of the drug even without any treatment. Despite the fact that it leaves the system through practically all the excretory organs, having been found in the sweat, saliva, urine, and intestinal mucus, it is eliminated very slowly and has been found in the urine as much as a month after the last dose.

The bromides are used in medicine to check *convulsions*, alleviate *pain*, to promote sleep, and to allay general nervous excitation. In *epilepsy* the bromides are the most potent remedial agents that we possess. Their influence, however, is that of a suppressant and rarely, if ever, do they produce a true cure; while under their use the patient may remain free from seizures for months and even years, their withdrawal is generally followed by a return of symptoms. In *tetanus* the fact that they can be given in almost unlimited quantity without serious depression of the circulation renders them of peculiar value for the control of the convulsions. In *strychnine poisoning*, although theoretically important, their action is generally too slow to be of much practical utility. As analgesics the bromides when given by themselves are of only secondary power, but they greatly enhance the anodyne effects of other drugs such as morphine or acetanilid. In *insomnia* they have been greatly abused. They differ sharply from the true somnifacients, such as chloral, in the fact that in ordinary quantity they have almost no depressant action upon the intellectual centers. Their value in promoting sleep is due rather to the obtunding of the general sensibilities so that those distractions, such as noise and bodily discomforts, which may act as contributing causes to the wakefulness, are less potent. They have been used very freely in all forms of functional disorders of the nervous system for some of which they are very useful, but for others entirely unsuited. In *hysteria* they are almost habitually prescribed, but it is extremely doubtful whether they have any effect which cannot be ascribed to the mere effect of taking medicine, at least as far as the immediate relief of symptoms. In *neurasthenia* their analgesic properties often make them useful and there is reason to believe that at times they may exercise a favorable influence upon the metabolism of the nerve centers. In *vomiting* of reflex origin, as that of pregnancy, at times they are of service. Among other conditions in which they are frequently employed may be mentioned *alcoholism, delirium tremens,* various forms of *sexual excitement,* as *nymphomania, urethral fever,* etc.

The dose of potassium bromide varies much according to the purpose for which it is administered and the length of time over which it is employed. In conditions like epilepsy in which the use of the drug is continued, once the system has come under its influence relatively small doses are required to maintain the beneficial impression. Thus, while in the beginning of the treatment 1 or 2 drachms (3.9–7.7 Gm.) a day may be required, after the action of the bromide has once been well established their influence may often be continued by 8 or 10 grains (0.5–0.65 Gm.) three times a day. In tetanus it is essential that large quantities be exhibited; as much as from one-half to one ounce (15.5–31 Gm.) should be administered in the twenty-four hours. When only one dose is given very large quantities may be safely administered, thus for the relief of pain a drachm is generally required and in severe strychnine poisoning one-half ounce (15.5 Gm.), properly diluted, may be exhibited at once.

Dose, ten to forty-five grains (0.65–3.0 Gm.).

POTASSII CARBONAS. U. S., Br.

POTASSIUM CARBONATE Pot. Carb. [Salt of Tartar]

"Potassium Carbonate, when dried to constant weight at 180° C., contains not less than 99 per cent. of K_2CO_3. It contains not more than 15 per cent. of water." *U. S.* "Potassium Carbonate may be obtained by the interaction of potassium sulphate and calcium carbonate. It contains not less than 81.5 per cent. of pure potassium carbonate, K_2CO_3." *Br.*

Carbonate of Potassa from Pearlash; Salt of Wormwood; Potassii Carbonas Purus, Sal Tartari; Kali Carbonicum, Carbonas Potassicus, s. Kalicus; Subcarbonas Potassicus; Carbonate Neutre de Potasse, Carbonate de Potasse, Sel de Tartre, *Fr.;* Kalium Karbonicum, *P. G.;* Kohlensaures kali, Kaliumcarbonat, *G.;* Carbonato di potassio, *It.;* Carbonato potasico, *Sp.*

The present U. S. Pharmacopœia does not give a process for this salt. That formerly official was to purify the impure *potassium carbonate,* or pearlash. This generally contains certain insoluble impurities, as well as small portions of potassium sulphate, silicate, and chloride.

Impure Potassium Carbonate (Potassii Carbonas Impura) was official in 1870. It is commonly known as *Pearlash.*

Preparation.—Potash and pearlash of commerce were formerly procured exclusively from the ashes of wood by lixiviation, and the subsequent evaporation of the solution obtained. The alkali exists in the wood in combination with various organic acids, and is left behind after the incineration, principally in the form of carbonate according to the following reaction, taking the acetate as an example:

$$2KC_2H_3O_2 + O_4 = K_2CO_3 + CO_2 + 3H_2O$$

The wood is burned on the ground, in a place sheltered from the wind. The ashes consist of a soluble and an insoluble portion. The soluble part is made up of potassium carbonate, together with potassium sulphate, phosphate, and silicate, and potassium and sodium chlorides; the insoluble portion, of calcium and aluminum salts, oxidized iron and manganese carbonate and phosphate, and a little carbonaceous matter that has escaped combustion. The ashes are lixiviated in barrels with the addition of a portion of lime, and the soluble substances above mentioned are taken up. The lixivium is then evaporated in large iron kettles (or pots—hence the name *potash*), which for several days are kept constantly full. The evaporation is continued until the mass has become of a black color and of the consistence of brown sugar. It is now subjected to a powerful heat by means of which the remainder of organic matter is burnt up and the mass becomes of a bluish-white color. The extraction from wood ashes is no longer practised in the United States, but is still carried out, to some extent in Canada and the northern countries of Europe, especially Russia.

Within recent years the residues of beet root molasses, after fermentation of the sugar and distillation of the spirit, have served as a source of potash. The molasses contains 40 to 50 per cent. of sugar and 3 to 4 per cent. of potassium salts. The *suint* of sheep's wool constitutes another source of potash. The potassium in this case being combined with fatty substances.

Most of the potassium carbonate of to-day is produced from potassium sulphate, either the crude salt from Stassfurt deposits or that obtained from the crude potassium chloride of the same locality. This is converted into carbonate by a process analogous to Leblanc's soda process. The principle of the ammonia soda process can also be applied to the crude potassium chloride of Stassfurt, with this difference in the practical operation, that, because of the ready solubility of the acid potassium carbonate, trimethylamine is used instead of ammonia, as the chloride of this base is much more soluble than is ammonium chloride.

The most important of the German potassium beds consist either of *sylvite,* a native potassium chloride or of *carnallite,* a double magnesio-potassium chloride. These overlie a deposit of sodium chloride at Stassfurt, near Magdeburg, Prussia. Another extensive deposit is near Muhlhausen, Alsace.

Crude potash is prepared in large amount from German rock salt deposits, in a manner analogous to the preparation of sodium carbonate from sodium chloride. The natural mixture of magnesium and potassium chlorides may also be saturated with carbon dioxide, when an insoluble double salt separates out.

$$3MgCO_3 + 2KCl + CO_2 + 9H_2O = 2(MgCO_3.KHCO_3.4H_2O) + MgCl_2$$

By heating this with water under pressure it decomposes into insoluble magnesium carbonate and soluble potassium carbonate, which remains in solution and is obtained therefrom by evaporation.

$$2MgCO_3.KHCO_3.4H_2O = K_2CO_3 + 2MgCO_3 + 5H_2O + CO_2$$

Potassium carbonate may be produced from crude potassium sulphate by the following reaction:

$$K_2SO_4 + CaCO_3 = K_2CO_3 + CaSO_4$$

Feldspar, marl and other minerals, rich in potassium compounds, are occasionally utilized for the production of potassium carbonate and other salts of the element.

During the World War potash salts were very scarce and high in price in the United States for many months. A number of sources were utilized economically at that time which in times of peace are too expensive. Among these wartime processes was the commercial utilization of seaweed on the Pacific coast. A five million dollar plant was operated for a time near San Diego, Calif., utilizing various species of seaweed, the species *Macrocystis pyrifera* being the one principally used. Besides potassium salts, iodine, acetates and acetone were produced by the process employed. (See *A. J. P.,* 1918, xc, 591.) There are immense deposits of *alunite,* a basic potassium aluminum sulphate, in Utah which are worked for their potash content to a certain extent.

Crude potash occurs commercially in the form of fused masses, of a stony appearance and hardness, and a caustic burning taste. Its color varies from a pale greenish-gray to reddish and dark brown. When exposed to the air, it absorbs moisture and deliquesces, and, if sufficiently long exposed, finally becomes liquid. Pearlash is of a white color, with usually a tinge of blue.

Pearlash, from its impurity, is never used as a medicine. Inasmuch as potassium carbonate is now largely made electrolytically from the chloride, the presence of potassium chlorate as an impurity has been reported in the commercial carbonate.

Potassium carbonate crystallizes with half a molecule of water and theoretically should contain, therefore, about 88 per cent. of anhydrous salt. Practically, however, it usually contains also some adherent water and the Pharmacopœia of the U. S. allows 15 per cent. of moisture and the Br. 18.5 per cent. It will absorb upwards of 28 per cent. of moisture before deliquescing.

Description and Physical Properties.—"A white, granular powder, odorless, and having a strongly alkaline taste. It is very deliquescent. One Gm. of Potassium Carbonate is soluble in 0.9 cc. of water at 25° C. One Gm. is soluble in 0.7 cc. of boiling water. It is insoluble in alcohol. When heating to 180° C., the salt loses all the water which it may have retained or absorbed. At a bright red heat it melts, and at a white heat it is volatilized.

"An aqueous solution of Potassium Carbonate (1 in 20) is strongly alkaline to litmus paper and to phenolphthalein T.S., and effervesces with acids. An aqueous solution of the salt (1 in 10) responds to the reactions for potassium.

"No residue is left on dissolving 1 Gm. of Potassium Carbonate in 20 cc. of distilled water (*insoluble impurities*). An aqueous solution of Potassium Carbonate (1 in 50), mixed with a slight excess of hydrochloric acid, meets the requirements of the test for *heavy metals.* Dry about 3 Gm. of Potassium Carbonate, accurately weighed, to constant weight, at 180° C.: the loss does not exceed 15 per cent. (*water*).

"**Assay.**—Dry Potassium Carbonate to constant weight at 180° C., weigh accurately about 3 Gm. of the dried salt in a stoppered weighing bottle, dissolve the salt in 25 cc. of distilled water, and titrate with normal sulphuric acid, methyl orange T.S. being used as indicator. Each cc. of normal sulphuric acid corresponds to 0.06911 Gm. of K_2CO_3.

"Preserve in air-tight containers." *U. S.*

"A white crystalline powder, very deliquescent. Taste alkaline and caustic. Soluble in 1 part of *water;* insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium and of carbonates. 1 gramme requires for neutralisation not less than 11.8 millilitres of *H/1 solution of sulphuric acid.* Loses not more than 18.5 per cent. of its weight when exposed to a red heat. Yields no characteristic *reactions* for copper, aluminum, calcium, magnesium, sodium, cyanides, nitrates, sulphates, sulphides, or thiosulphates, not more than the slightest *reactions* for iron, and no strongly marked *reactions* for chlorides. *Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million." *Br.*

Potassium percarbonate, $K_2C_2O_6$, was made by Constans and von Hansen by electrolyzing a saturated solution of potassium carbonate, and gradually lowering the temperature. It is a bluish amorphous powder, hygroscopic and decomposing water at ordinary temperatures, bicarbonate being formed. (*Chem. News,* 1897, 170; 1898, 65.)

It is incompatible with acids and acidulous salts, ammonium chloride and acetate, lime water, calcium chloride, magnesium sulphate, alum, tartar emetic, silver nitrate, ammoniated copper and ammoniated iron, ferrous sulphate, tincture of ferric chloride, calomel and corrosive sublimate, lead acetate and subacetate, and zinc sulphate. It is not decomposed by iron and potassium tartrate.

Uses.—Potassium carbonate is too irritant to be valuable as a gastric antacid. It was at one time largely used as a systemic alkalizer and diuretic in the treatment of *rheumatic* and *gouty* conditions, but has been largely replaced by the less irritating citrate and acetate. Its greatest importance is for pharmaceutical and chemical manipulations.

In large quantities it acts as a corrosive poison, and is capable of producing death in a few hours. The symptoms and treatment are similar to those described under *Potassii Hydroxidum.*

Dose, five to twenty grains (0.3–1.3 Gm.).

Off. Prep.—Mistura Carminativa, *N. F.;* Unguentum Sulphuris Alkalinum, *N. F.;* Mistura Rhei Alkalina, *N. F.;* Syrupus Rhei, *U. S.;* Sal Vichyanum Factitium, *N. F.;* Tinctura Rhei Aquosa, *N. F.*

POTASSII CHLORAS. U. S., Br.

POTASSIUM CHLORATE Pot. Chloras

"Potassium Chlorate contains not less than 99 per cent. of $KClO_3$. *Great caution should be observed in handling it,* as dangerous explosions are liable to occur when it is heated or subjected to concussion or to trituration with organic substances such as cork, tannic acid, dust, sucrose, etc., or with charcoal, sulphur, sulphides, hypophosphites, or other easily oxidizable substances." *U. S.* "Potassium Chlorate, $KClO_3$, may be obtained by passing chlorine into water holding lime or magnesia in suspension, treating the clarified liquid with potassium chloride, and subsequently crystallising out the potassium chloride." *Br.*

Chlorate of Potash; Kali Oxymuriaticum, Kali Muriaticum Oxygenatum, Chloras Potassicus, s. Kalicus; Hyperoxymuriate of Potassa; Chlorate de Potassium, *Fr.;* Kalium Chloricum, *P. G.;* Kaliumchlorat, Chlorsaures Kali, *G.;* Clorato di potassio, *It.;* Clorato Potasico, Sal de Berthollet, *Sp.*

Preparation.—Neither the U. S. nor the Br. at present gives a process for the manufacture of potassium chlorate. It may be prepared on a small scale by passing chlorine into a hot concentrated solution of potassium hydroxide. It was formerly manufactured by the interaction between calcium chlorate and potassium chloride. In this process chlorine is passed into a solution of milk of lime having a specific gravity of 1.04 until the liquid is nearly saturated. The clear solution is evaporated until it has a specific gravity of 1.18, and then potassium chloride added, and the mixture boiled down until a specific gravity of 1.28 is attained. On cooling, crystals of potassium chlorate separate out. The reactions here are

$$6Ca(OH)_2 + 6Cl_2 = 5CaCl_2 + Ca(ClO_3)_2 + 6H_2O$$

$$Ca(ClO_3)_2 + 2KCl = CaCl_2 + 2KClO_3$$

Pechiney's improvement on this process is to separate the greater part of the calcium *chloride* from the calcium *chlorate* before adding the potassium chloride. For details, see *N. R.,* Feb., 1882.

The potassium chlorate of commerce has also been prepared by the reaction of solutions of potassium chloride and calcium hypochlorite, with the assistance of heat.

Potassium chlorate is now principally made commercially by the electrolysis of alkaline solutions at Niagara Falls, and elsewhere, in this country and in various places in Europe. The potassium chloride, on electrolysis in a lead-lined cell without diaphragm, yields first potassium hypochlorite, but as the temperature of the bath is kept above 50° C., it is changed to a mixture of chlorate and chloride, from which, on cooling, the former crystallizes out.

The anodes consist of an alloy of iridium 10 per cent., and platinum 90 per cent. in plates 1 mm. thick. The cathodes are formed of an iron-nickel alloy coated with asbestos. The cells are insulated by immersion in baths of oil. Working with pure potassium chloride the chlorate is easily obtained of 99 per cent. purity by this process.

Description and Physical Properties.—"Colorless, odorless, lustrous, monoclinic prisms or plates, or a white, granular powder. It is stable in the air. One Gm. of Potassium Chlorate is soluble in 16.5 cc. of water at 25° C. One Gm. is soluble in 1.8 cc. of boiling water. It is almost insoluble in alcohol but is soluble in glycerin.

"When heated to about 360° C., the salt gives off oxygen and finally leaves a residue of potassium chloride, which is readily soluble in water and which responds to the reactions for potassium, and for chlorides. Add about 0.2 Gm. of Potassium Chlorate to 1 cc. of hydrochloric acid: the liquid assumes a deep greenish-yellow color, and chlorine and oxides of chlorine are evolved.

"An aqueous solution of the salt (1 in 20) is neutral to litmus paper. An aqueous solution of the salt meets the requirements of the test for *heavy metals.*

"Preserve in well-closed containers." *U. S.*

"Colorless monoclinic crystals. Taste cool, saline. Soluble in 16 parts of *water*. Moistened with *hydrochloric acid* it evolves a yellow gas with an odor of chlorine. Yields no characteristic *reactions* for iron, calcium, magnesium, sodium, ammonium, or nitrates, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Potassium chlorate easily yields its excess of oxygen and when triturated with strongly reducing substances like sulphur, phosphorus, sugar, charcoal, etc., is liable to cause violent explosions. In solution it acts as an oxidizing agent only when heated. By sulphuric acid it is decomposed, liberating an explosive gas, *chlorine dioxide.* When decomposed with hydrochloric acid, there is formed a substance formerly called *euchlorine,* which, however, appears to be a mixture of chlorine and chlorine dioxide.

It is the chlorine dioxide that gives the bright-yellow color to a solution of potassium chlorate in concentrated hydrochloric acid. Chlorine dioxide decomposes in the presence of water to form a mixture of chlorous and chloric acids.

Assay.—"Dissolve about 0.1 Gm. of Potassium Chlorate, accurately weighed, in 10 cc. of distilled water. Transfer to a 250 cc. flask, and add 50 cc. of acid ferrous sulphate T.S. to the solution. Prepare a valve stopper by taking a piece of rubber tubing of convenient diameter and about 5 cm. in length, placing a piece of glass rod in one end and slipping the other end over a glass tube which passes through a perforated stopper of a size convenient to fit the flask used. Cut a longitudinal slit about 15 mm. long in one side of the rubber tube about half way up. Insert this stopper in the flask and boil the mixture for ten minutes. Cool the mixture, add 10 cc. of manganous sulphate T.S., and titrate the excess of ferrous sulphate with tenth-normal potassium permanganate. Conduct a blank experiment with another portion of 50 cc. of acid ferrous sulphate T.S. and subtract the result of the former titration from that of the latter. Each cc. of tenth-normal potassium permanganate corresponds to 0.002043 Gm. of $KClO_3$." *U. S.*

Frank X. Moerk (*J. A. P. A.*, 1913, p. 155) reviews various methods for the determination of chlorates and recommends the following: Place 0.1 Gm. of the salt in a glass-stoppered bottle and add 10 cc. of distilled water and 15 cc. 10 per cent. potassium bromide solution, and 20 cc. HCl (sp. gr. 1.20) and allow to stand 40 minutes tightly stoppered. Cool by immersing in water, add 20 cc. potassium iodide solution (10 per cent.), carefully rinsing the stopper and neck of the bottle, and titrate with tenth-normal sodium thiosulphate V.S. A blank test should be made with the reagents to prove that no iodine is liberated by them alone.

Potassium chlorate is *incompatible* in the dry state with all easily oxidizable substances, such as sulphur, cyanides and most of the organic compounds. With ammonium chloride it is said to also form an explosive compound. In solution it is decomposed by the mineral acids, ammonium chloride, etc.

Uses.—In the belief that potassium chlorate yielded oxygen in the system, it was formerly used in the treatment of various infectious diseases as well as a local disinfectant, but as decomposition of the salt takes place only in highly acid media this liberation in the body cannot occur. As a local antiseptic it is extremely feeble. According to the experiments of Sternberg a 4 per cent. solution—which is almost saturation at ordinary temperatures—is without germicidal power. It is used at present solely as a local remedy in *stomatitis, pharyngitis, vaginitis,* and other forms of *catarrh* as well as in *hemorrhoids* and *indolent ulcers.* Such slight beneficial influence as it may exert in these conditions is due to its stimulant saline properties combined with a mild astringent effect. On the theory that it would be eliminated through the salivary glands and keep the mouth constantly bathed with a solution, it has been recommended to administer the drug internally in mercurial *ptyalism* and other inflammatory conditions of the buccal cavity, but as the larger portion of the drug is excreted through the kidneys this use does not commend itself to the thinking physician.

In overdose potassium chlorate is an active poison, four drachms of it having caused death in the adult. The symptoms produced are violent vomiting, profuse diarrhea, excessive dyspnea, great failure of the heart's action, and marked cyanosis. The urine is lessened in quantity, albuminous, often of a dark reddish-brown or blackish color, and containing tube casts and the débris of blood corpuscles. In some cases there have been marked nervous symptoms, such as cramps, delirium, coma, etc. The lesions found after death are those of gastro-enteritis and acute nephritis, with alteration in the character of the blood due to the development in it of methemoglobin. On account of their irritant action on the kidneys, large doses are especially dangerous in *diphtheria.*

Dose, from five to fifteen grains (0.32–1.0 Gm.).

Off. Prep.—Trochiscus Potassii Chloratis, *Br.;* Gargarisma Guaiaci Compositum, *N. F.*

POTASSII CHLORIDUM. N. F.

POTASSIUM CHLORIDE Pot. Chloride.

"Potassium Chloride contains, when dried to constant weight at 100° C., not less than 99 per cent. of KCl (74.56)." *N. F.*

Kalium chloridum (chloratum); Sal digestivum Sylvii; Sel digestif, *Fr.*

This salt is found native in the free condition forming the basis of *sylvite* and in combination with magnesium chloride as *carnallite.*

Description and Physical Properties.—"Potassium Chloride occurs in colorless, elongated, prismatic, or cubical crystals, or as a white, granular powder; permanent in dry air. Odorless; taste saline. One Gm. dissolves in 2.8 cc. of water at 25° C., slightly more soluble in boiling water; insoluble in alcohol.

"An aqueous solution of the salt (1 in 10) is clear, and neutral to litmus. When heated, the dry salt decrepitates. To a non-luminous flame it imparts a violet color unmasked by yellow. An aqueous solution of the salt yields with silver nitrate T.S. a white, curdy precipitate, insoluble in nitric acid but soluble in an excess of ammonia water.

"Boil 5 cc. of an aqueous solution of the salt (1 in 10) in a test tube, then add an equal volume of barium hydroxide T.S. and stopper the tube; the solution is not rendered cloudy within fifteen minutes (*calcium or magnesium*). Dissolve 2 Gm. of the salt in 6 cc. of distilled water, add 1 cc. of chloroform, and then add, drop by drop, with constant agitation, 5 cc. of half-strength chlorine water; the chloroform does not acquire a transient violet or permanent orange color (*iodide or bromide*). An aqueous solution of the salt meets the requirements of the Test for arsenic. An aqueous solution of the salt does not respond to the Test for heavy metals.

"**Assay.**—Dissolve about 0.25 Gm. of Potassium Chloride, previously dried to constant weight at 100° C. and accurately weighed, in 25 cc. of distilled water in a 200 cc. measuring flask. Add 50 cc. of tenth-normal silver nitrate to the solution, then 5 cc. of nitric acid, afterward sufficient distilled water to make 200 cc. and mix thoroughly. Filter the mixture through a dry filter, reject the first 20 cc. of the filtrate, collect the following 100 cc. of filtrate, add to this 2 cc. of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium thiocyanate, until the supernatant liquid remains reddish after it is well shaken. Each cc. of tenth-normal silver nitrate corresponds to 0.007456 Gm. of KCl. Each Gm. of Potassium Chloride, dried to constant weight, corresponds to not less than 132.8 cc. of tenth-normal silver nitrate." *N. F.*

Uses.—Potassium chloride is recognized by the N. F. because of its presence in certain mineral waters, imitations of which are official. There is no reason to believe that the small amount of potassium chloride present in these compound salts modifies materially their action.

Potassium chloride is recognized among the U. S. P. reagents because it is an ingredient in the Locke-Ringer solution. (See Part III; also under *Liquor Sodii Chloridi Physiologicus.*)

Dose, ten to twenty grains (0.6–1.2 Gm.).

Off. Prep.—Liquor Hydrastinæ Compositus, *N. F.;* Sal Kissengense Factitium, *N. F.;* Sal Kissengense Factitium Effervescens, *N. F.*

POTASSII CITRAS. U. S., Br.

POTASSIUM CITRATE Pot. Cit.

"Potassium Citrate, when dried to constant weight over sulphuric acid, contains not less than 99 per cent. of $K_3C_6H_5O_7.H_2O$." *U. S.*

"Potassium Citrate may be obtained by the interaction of citric acid and potassium carbonate. It contains not less than 99 per cent. of pure potassium citrate, $K_3C_6H_5O_7,H_2O$." *Br.*

Kalium Citricum, Citras Potassicus, s. Kalicus; Citrate of Potash; Salt of Riverius; Citrate de Potasse, *Fr.;* Kaliumcitrat, Citronsaures Kali, *G.*

No process for this salt is at present official. In the U. S. formula of 1870, it was made by the reaction between citric acid and potassium bicarbonate, the latter ingredient being preferred to the carbonate on account of its greater purity. The British 1885 process differed only in the use of the carbonate instead of the bicarbonate, and in providing more carefully for an exact neutralization.

Description and Physical Properties.—"Transparent, prismatic crystals, or a white, granular powder. It is odorless, and has a cooling, saline taste, and is deliquescent when exposed to moist air. One Gm. of Potassium Citrate is soluble in 0.6 cc. of water at 25° C. It is almost insoluble in alcohol and is freely soluble in glycerin.

"When heated above 100° C., the salt begins to lose water and at about 200° C., the water of crystallization is completely volatilized. At a higher temperature the salt begins to decompose, turns brown, and upon further heating carbonizes and emits inflammable gases which have a very pungent, acrid odor. After heating to redness, there remains a residue of carbon and potassium carbonate which has an alkaline reaction and effervesces with acids. An aqueous solution of Potassium Citrate (1 in 10) responds to the reactions for potassium, and for citrates.

"An aqueous solution of Potassium Citrate (1 in 20) is alkaline to litmus paper, but a 10 cc. portion of the solution is not reddened by one drop of phenolphthalein T.S. A solution of 1 Gm. of Potassium Citrate in 1 cc. of distilled water does not deposit a crystalline precipitate on the addition of 1 cc. of acetic acid (*tartrate*). An aqueous solution of the salt meets the requirements of the test for *heavy metals.* An aqueous solution of the salt meets the requirements of the test for *arsenic.*

"**Assay.**—Dry the salt to constant weight over sulphuric acid and proceed as directed under the assay for alkali salts or organic acids. Each cc. of half-normal sulphuric acid corresponds to 0.05407 Gm. of $K_3C_6H_5O_7.H_2O$.

"Preserve in well-closed containers." *U. S.*

The British Pharmacopœia gives the following tests of its character:

"A white, granular, or crystalline powder. Taste saline, feebly acid. Soluble in 1 part of *water.* Yields the *reactions* characteristic of potassium and of citrates. 1 gramme, heated to redness till gases cease to be evolved, leaves an alkaline residue which, when treated with *water,* filtered, and well washed, yields a clear solution requiring for neutralisation not less than 18.3 millilitres of *N/2 solution of sulphuric acid.*

Yields no characteristic *reactions* for iron, calcium, magnesium, sodium, carbonates, or tartrates, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million." *Br.*

Uses.—Potassium citrate is a type of those drugs which increase various secretions by what is known as their salt action. This group of drugs, which includes most of the non-toxic crystalloids, act by increasing the saline concentration of the blood, disturbing the osmotic balance between this fluid and the surrounding tissues thereby attracting water into the vessels and tending towards the production of a hydremic state. This tendency towards an increase in the volume of the blood is counteracted by greater activity on the part of the glandular structures. Not only is the secretion of urine greater, but there is also an increase in the bronchial, sweat, and other glands. The therapeutic uses of potassium citrate, however, are not due alone to this action. The citrates being oxidized in the body into carbonates, the salt tends to correct any systemic hyperacidity; and the potassium apparently increases the completeness of bodily combustion. This combination of actions makes the drug of peculiar value in those forms of metabolic disturbances accompanied with the over-production of uric acid, such as *acute* or *chronic rheumatism* and *gout.* It is, however, a valuable drug in a large variety of other conditions. Probably its most frequent use to-day is as an expectorant in the early stages of *acute bronchitis* or *tracheitis;* by increasing the secretion of the mucous glands it indirectly exercises a sedative action on the inflammatory mucous membrane. It is valuable as a sudorific in the early stage of the milder infections; it is sometimes of service as a diuretic although caution must be observed in its use when there is serious disease of the kidneys. In cases of *cystitis* when the urine is excessively acid it is especially valuable. It may be most pleasantly exhibited in conjunction with lemon juice which in no way lessens the alkalizing effect.

Dose, of the citrate, from fifteen to forty grains (1–2.6 Gm.). When a decided effect upon the system is desirable, as much as an ounce (31 Gm.) of it may be given in twenty-four hours.

Off. Prep.—Potassii Citras Effervescens, *U. S.*

POTASSII CITRAS EFFERVESCENS. U. S.

EFFERVESCENT POTASSIUM CITRATE Pot. Cit. Eff.

"Potassium Citrate, 200 Gm.; Sodium Bicarbonate, dried and powdered, 477 Gm.; Tartaric Acid, dried and powdered, 252 Gm.; Citric Acid, uneffloresced crystals, 162 Gm.; to make about 1000 Gm. Dry the potassium citrate on a water bath until it ceases to lose weight, and powder the dried salt. Mix intimately with the powdered citric acid and tartaric acid, and thoroughly incorporate the sodium bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish in an oven heated between 93° and 104° C. Manipulate the mixture carefully with a wooden spatula until it becomes moist, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. Immediately transfer the salt to suitable containers and seal them tightly. Care must be taken to prevent the product from coming in contact with air containing moisture." *U. S.*

This official effervescent salt affords an agreeable mode of administering potassium citrate. It is more prone to exert a laxative effect because of the sodium tartrate formed.

Dose, from one to two drachms (3.9–7.7 Gm.).

POTASSII ET SODII TARTRAS. U. S. (Br.)

POTASSIUM AND SODIUM TARTRATE Pot. et Sod. Tart. [Rochelle Salt]

"Potassium and Sodium Tartrate contains not less than 73.72 per cent. and not more than 77.39 per cent. of $KNaC_4H_4O_6$, corresponding to not less than 99 per cent. of the crystallized salt [$KNaC_4H_4O_6.4H_2O$]." *U. S.* "Sodium Potassium Tartrate may be obtained by neutralising Acid Potassium Tartrate with Sodium Carbonate. It contains not less than 98 per cent. of pure sodium potassium tartrate, $NaKC_4H_4O_6,4H_2O$." *Br.*

Sodii et Potassii Tartras, *Br.;* Sodium Potassium Tartrate; Tartrate of Potassium and Sodium; Soda Tartarata; Sodæ et Potassæ Tartras, *Br.* 1864, *U. S.* 1850; Sodæ Potassiotartras, Natro-kali Tartaricum; Tartarated Soda; Sal Polychrestum Seignetti, Tartras Potassico sodicus; Kalium Natrio Tartaricum, *Fr. Cod.;* Tartrate droit de Sodium et de Potassium, Sel de la Rochelle, Sel de Seignette, Soude Tartarisée, *Fr.;* Tartarus Natronatus, *P. G.;* Seignettesalz, Kaliumnatriumtartrat, *G.;* Tartrate sodico-potassico, *It.;* Tartrato sodico-potasico, *Sp.*

This salt cannot be made profitably on the small scale (for U. S. process, 1870, see the *U. S. Dispensatory,* 19th edition, page 1000); it is a double salt, consisting of a molecule of tartaric acid, $C_4H_4O_6.H_2$, in which one of the basic hydrogen atoms is replaced by potassium and the other by sodium; or it may be considered to be formed by the replacement of the hydrogen in the potassium bitartrate by sodium.

Description and Physical Properties.—"Colorless, transparent, rhombic prisms, or a white powder. It is odorless, and has a cooling, saline taste. The crystals effloresce slightly in dry air. One Gm. of Potassium and Sodium Tartrate is soluble in 0.9 cc. of water at 25° C. It is practically insoluble in alcohol.

"When heated to about 74° C., the salt fuses to a colorless liquid, which at a higher temperature froths, becomes brown, and is gradually carbonized, emitting inflammable vapors which have the odor of burning sugar. Finally a black residue is left, consisting of a mixture of potassium and sodium carbonates with carbon. To a non-luminous flame this residue imparts an intensely yellow color. An aqueous solution of the salt (1 in 20) yields a white, crystalline precipitate with an equal volume of acetic acid within fifteen minutes. An aqueous solution of the salt (1 in 10) responds to the reactions for tartrates.

"An aqueous solution of Potassium and Sodium Tartrate (1 in 20) is alkaline to litmus paper, but a 10 cc. portion of the solution is not reddened by a drop of phenolphthalein T.S. An aqueous solution of Potassium and Sodium Tartrate meets the requirements of the test for *heavy metals.* A 5 cc. portion of an aqueous solution of the salt (1 in 10) heated with sodium hydroxide T.S. does not evolve ammonia. Dissolve 10 Gm. of Potassium and Sodium Tartrate in 20 cc. of distilled water, add 2 cc. of sulphurous acid, and boil the mixture until the odor of sulphur dioxide is barely perceptible. Cool the solution, mix it with 1 cc. of sodium cyanide T.S., and follow this immediately with stronger ammonia T.S. until the solution has a slight odor of ammonia. When cold, transfer the solution to a 50 cc. graduated glass-stoppered cylinder, dilute it with sufficient distilled water to measure 50 cc., and add 3 drops of sodium sulphide T.S. After thoroughly mixing, the color produced in the solution, if any, when viewed downward against a white surface, is not greater than the color of a control solution prepared as follows: Dissolve 2 Gm. of reagent ammonium chloride in 20 cc. of distilled water, add 4 cc. of a solution containing 0.08 Gm. of lead nitrate in 1000 cc. of distilled water, and then 1 cc. of diluted hydrochloric acid. Treat this solution with the same quantities of sulphurous acid, sodium cyanide T.S. and stronger ammonia T.S., as used above, transfer it to another 50 cc. glass-stoppered cylinder, then dilute it with sufficient distilled water to make 50 cc., and add 3 drops of sodium sulphide T.S. Before adding the sodium sulphide T.S. the liquid must possess a distinct odor of ammonia, and the two cylinders used must be matched, be of practically colorless glass, and have the same internal diameter (*lead*).

"**Assay.**—Proceed as directed under the assay for alkali salts of organic acids. Each cc. of half-normal sulphuric acid corresponds to 0.05254 Gm. of $KNaC_4H_4O_6$.

"Preserve in well-closed containers." *U. S.*

"Trimetric prisms with hemihedral facets. Taste saline, cooling. Soluble in 1.5 parts of *water;* aqueous solution neutral to *litmus.* Yields the reactions characteristic of potassium, of sodium, and of tartrates. 1 gramme, heated to redness till gases cease to be evolved, leaves an alkaline residue which, when treated with *water,* filtered, and well washed, yields a clear solution requiring for neutralization not less than 13.9 millilitres of *N/2 solution of sulphuric acid.* Yields no characteristic *reactions* for copper, iron, calcium, ammonium, chlorides, or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 2 parts per million." *Br.*

When the salt is exposed to a very strong heat, it becomes blackened, and gives out inflammable gases with the odor of burnt sugar, the tartaric acid being destroyed, and a mixture of potassium and sodium carbonates left. It is incompatible with most acids, and with nearly all acid salts except potassium bitartrate. It is also decomposed by lead acetate and subacetate, silver nitrate, and by the soluble calcium and barium salts unless the solution of the tartrate be considerably diluted.

The way in which the acids act in decomposing potassium and sodium tartrate is by combining with the sodium, and throwing down potassium bitartrate as a crystalline precipitate. This double salt was discovered by Seignette, an apothecary of Rochelle, and hence is frequently called *Seignette's salt* or *Rochelle salt.*

Uses.—This salt is a mild, saline purgative, well suited to delicate and irritable stomachs, being among the mildest and least unpalatable of the neutral salts. It is an ingredient in the effervescing aperient called Seidlitz powders. (See *Pulvis Effervescens Compositus.*)

Potassium and magnesium tartrate, formed by saturating cream of tartar with magnesium carbonate, has been proposed by Maillier for use as a safe, pleasant purgative.

Dose, as a purge, from half an ounce to an ounce (15.5–31 Gm.).

Off. Prep.—Pulvis Effervescens Compositus, *U. S. (Br.).*

POTASSII HYDROXIDUM. U. S. (Br.)

POTASSIUM HYDROXIDE Pot. Hydrox.
[Caustic Potash]

"Potassium Hydroxide contains not less than 85 per cent. of KOH. *Great caution is necessary in handling it, as it rapidly destroys organic tissues." U. S.* "Potassium Hydroxide may be obtained by the interaction of potassium carbonate and calcium hydroxide. It contains not less than 85 per cent. of pure potassium hydroxide, KOH." *Br.*

Potassa Caustica, *Br.;* Kali Purum; Potassa, Hydrate of Potassa, Potassæ (Potassii) Hydras, Kali Hydricum Fusum, Lapis Causticus Chirurgorum Hydras Kalicus; Kalium Hydroxydatum Purum, *Fr. Cod.;* Hydroxide de Potassium, Potasse caustique, Potassee Fondue, Pierre à cautère, *Fr.;* Kali Causticum, *P. G.;* Kaliumhydroxyd, Kalium-Hydrat, Kaustisches Kali, Ætzkali, *G.;* Potassa caustica, *It.;* Hidrato potasico, *Sp.*

Formerly both of the Pharmacopœias recognized processes for the manufacture of potassium hydroxide which were based upon decomposition of a solution of potassium carbonate by means of calcium hydroxide and the evaporation of the resultant solution of potassium hydroxide. The evaporation must be performed in metallic vessels because of the injurious effect of the alkali upon glass. The method in principle is still employed to some extent on a commercial scale. Potassium hydroxide is now prepared at Niagara Falls, N. Y., by the electrolysis of strong potassium chloride solution. The metal at the cathode acts with water to form potassium hydroxide and free hydrogen, while chlorine is liberated at the anode. The ordinary white flint glass bottles are not suitable for preserving this solution, the bottles in which it is preserved should be of green glass or some other form of hard glass and the stoppers should be of rubber or of glass coated with petrolatum.

Description and Physical Properties.—"Dry, white, or nearly white, fused masses, or sticks, hard and brittle, showing a crystalline fracture. When exposed to the air, it rapidly absorbs carbon dioxide and moisture, and deliquesces. One Gm. of Potassium Hydroxide is soluble in 0.9 cc. of water, in about 3 cc. of alcohol, and in 2.5 cc. of glycerin, at 25° C. One Gm. is soluble in 0.6 cc. of boiling water. It is very soluble in boiling alcohol.

"An aqueous solution of Potassium Hydroxide, even when greatly diluted, is strongly alkaline to litmus paper. An aqueous solution of Potassium Hydroxide (1 in 25) responds to the reactions for potassium.

"An aqueous solution of Potassium Hydroxide (1 in 20) is clear and colorless (*organic matter or insoluble impurities*). An aqueous solution of Potassium Hydroxide (1 in 50) slightly acidulated with hydrochloric acid meets the requirements of the test for *heavy metals*.

"**Assay.**—Place about 10 Gm. of Potassium Hydroxide in a glass-stoppered weighing bottle, weigh accurately, transfer to a 500 cc. graduated flask, and dissolve it in 250 cc. of recently boiled distilled water. Add 30 cc. of barium chloride T.S., fill the flask to the mark with recently boiled distilled water, and thoroughly agitate the liquid. Filter the liquid in the flask through a dry filter into a dry flask, rejecting the first 20 cc., and titrate 200 cc. of the clear filtrate with normal hydrochloric acid, using phenolphthalein T.S. as indicator. Each cc. of normal hydrochloric acid corresponds to 0.05611 Gm. of KOH.

"Preserve in air-tight containers. If bottles are used, they must be made of hard glass, and cork stoppers should be paraffined." *U. S.*

"In hard white pencils or cakes, very deliquescent, very alkaline and corrosive. Soluble in 0.5 part of *water*, and in 3 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium. 1 gramme dissolved in *water* or in *alcohol* (90 per cent.) leaves only a slight sediment; the solution requires for neutralisation not less than 15.1 millilitres of *N/1 solution of sulphuric acid*. Yields no characteristic *reactions* for lead, copper, or arsenic." *Br.*

The *white stick caustic potassa* as found in commerce often contains from 15 to 28 per cent. of water. On account of its deliquescent property, and its strong attraction for carbon dioxide, potassium hydroxide requires to be kept in very closely stoppered bottles.

Official potassium hydroxide may be converted into a product of a much higher degree of purity by digestion in alcohol—which takes up only the hydroxide—evaporating the solution to dryness, and fusing the dry mass obtained. *Potassium hydroxide*, when thus procured, is called *potash by alcohol*. It is generally in flat white pieces, which are dry, hard and brittle. Its other properties are similar to those of the official hydroxide above described.

Uses.—Probably because of its powerful effect in dissolving the bodily tissues potassium hydroxide is a very potent escharotic. It is the old *causticum commune acerrimum* or *strongest common caustic*. Its action is not only very thorough, but it penetrates more deeply than either silver nitrate or nitric acid. It is also powerfully germicidal; although Sternberg found that it required a ten per cent. solution to destroy pus cocci in two hours, most authorities agree that one per cent. is sufficient to kill all vegetating bacteria. Because of difficulty of controlling its action it is not commonly employed for the destruction of benign growths as *warts*, but in *poisoned bites*, especially by *rabid animals*, the thoroughness of its action is an advantage.

In the application of potassium hydroxide as a caustic the surrounding skin should be protected by petrolatum. A stick of the caustic previously moistened is rubbed over the area to be cauterized. After the action is considered to have proceeded far enough, the part should be washed with diluted acetic acid and then cleansed with distilled water. In forming from it solutions of potassium hydroxide of definite strength, whether for medicinal or for pharmaceutical use, an allowance should be made for the percentage of water it always contains. (See *Liquor Potassii Hydroxidi.*)

Poisoning.—Because of their powerful caustic action, the hydroxides are dangerous poisons. Because of the frequent use of sodium hydroxide in the kitchen accidental poisoning, especially in children, is not uncommon. The symptoms are violent pains in the throat and epigastrium, vomiting—the matters rejected at first being the contents of the stomach, later of a brown color from the presence of decomposed blood—followed by collapse. The mucous membranes of the mouth have a slippery feel and are swollen and often brown in color. In those cases which do not immediately prove fatal there is caused so much destruction of the membranes of the esophagus that stricture develops and the patient is unable to swallow, and death from starvation may occur after some time has elapsed.

The treatment consists in the prompt neutralization of the alkali. For this probably the best agent is acetic acid which, in the form of vinegar, is usually at hand; one or two tablespoonfuls diluted with water may be given at a dose. Olive oil, or other bland fixed oil, is also very useful, forming with the hydroxide a comparatively non-irritating soap and also acting as a demulcent to the inflamed tissue. In the absence of vinegar, other acids, as lemon or orange-juice, or even the mineral acids—if well diluted—may be employed. Subsequent treatment involves the combating of the collapse and the relief of such symptoms as arise.

Off. Prep.—Liquor Potassii Hydroxidi, *U. S. (Br.)*; Liquor Picis Alkalinus, *N. F.*; Potassa cum Calce, *N. F.*

POTASSII HYPOPHOSPHIS. N. F.

POTASSIUM HYPOPHOSPHITE Pot. Hypophos.

"Potassium Hypophosphite contains, when dried to constant weight over sulphuric acid, not less than 98 per cent. of KPH_2O_2 (104.16). Caution should be observed in dispensing Potassium Hypophosphite, as an explosion is liable to occur if it is triturated or heated with nitrates, chlorates, or other oxidizing agents." *N. F.*

Kalium Hypophosphorosum, Hypophosphis Potassicus, s. Kalicus; Hypophosphite de Potasse, *Fr.*; Unterphosphorigsaures Kali, *G.*

This salt is prepared by mixing solutions of calcium hypophosphite and potassium carbonate. As a result of double decomposition between the two salts, calcium carbonate and *potassium hypophosphite* are formed. The calcium carbonate is removed by filtration, and the clear solution is evaporated until a pellicle forms, after which it is constantly stirred, with continuance of the heat, until the salt granulates. The heat employed in the evaporation should be kept considerably below 100° C., for fear of explosion. If the salt be required pure, it should be dissolved in the granulated state, in official alcohol, and the solution evaporated to a syrupy consistence and then set aside to crystallize. The calcium hypophosphite may be prepared by a formula given under the head of *Calcii Hypophosphis*.

Description and Physical Properties.—"Potassium Hypophosphite occurs as white, opaque, hexagonal plates, or crystalline masses, or as a granular powder; odorless, and having a pungent, saline taste; very deliquescent. One Gm. of Potassium Hypophosphite dissolves in 0.6 cc. of water and in 9 cc. of alcohol at 25° C.; also in 0.4 cc. of boiling water and in 5 cc. of boiling alcohol.

"An aqueous solution of the salt (1 in 20) is neutral or slightly alkaline to litmus and yields with sodium bitartrate T.S. a white, crystalline precipitate. When heated in a dry test tube spontaneously inflammable hydrogen phosphide is evolved which burns with a bright yellow flame. When an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added drop by drop with agitation to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. Upon the further addition of the solution of Potassium Hypophosphite, the precipitate becomes gray from reduction to metallic mercury.

"A solution of 1 Gm. of the salt in about 10 cc. of distilled water requires not more than 1.5 cc. of tenth-normal hydrochloric acid for neutralization, methyl orange T.S. being used as indicator. Heat 5 cc. of an aqueous solution of the salt (1 in 5) with 0.5 cc. of diluted hydrochloric acid in a test tube on a water bath for thirty minutes; no offensive odors are developed. Measure 5 cc. of an aqueous solution of Potassium Hypophosphite (1 in 25) into a beaker containing 3 cc. of nitric acid diluted with about 10 cc. of distilled water, and evaporate the mixture to dryness on a water bath; the residue meets the requirements of the Test for arsenic. Add magnesia mixture T.S. to 10 cc. of an aqueous solution of the salt (1 in 20) made alkaline with ammonia water; it is not affected within one minute (*phosphates*).

"**Assay.**—Dissolve about 1 Gm. of Potassium Hypophosphite, dried to constant weight over sulphuric acid and accurately weighed, in 10 cc. of distilled water, add 10 cc. of nitric acid and evaporate it to dryness on a water bath. Then add 5 cc. of nitric acid and again evaporate it to dryness on a water bath. Dissolve the residue in 20 cc. of distilled water, add a drop of phenolphthalein T.S. and sufficient special potassium hydroxide T.S. (free from chloride) to produce a pink color, and then dilute it to exactly 100 cc. with distilled water. Transfer 10 cc. of this solution to a 100 cc. graduate flask, add 50 cc. of tenth-normal silver nitrate and thoroughly agitate the mixture. Gradually add reagent zinc oxide, in small portions, until the liquid is neutral to litmus paper. Then add distilled water to make 100 cc., mix thoroughly, and filter through a filter paper not previously moistened, rejecting the first 25 cc. of filtrate. Collect 50 cc. of the subsequent filtrate, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate to the production of a permanent red color. Each cc. of tenth-normal silver nitrate corresponds to 0.003472 Gm. of KPH_2O_2. Each Gm. of Potassium Hypophosphite, previously dried, corresponds to not less than 282.3 cc. of tenth-normal silver nitrate.

"Preserve it in well-closed containers, in a dry place." *N. F.*

Uses.—This salt was introduced along with the other hypophosphites because of the claims made by Churchill of their curative value in *phthisis* (see *Acidum hypophosphorosum*), but has no therapeutic virtues justifying its continued recognition.

Dose, eight to twenty grains (0.5–1.2 Gm.).

Off. Prep.—Syrupus Hypophosphitum, *N. F.*; Emulsum Olei Morrhuæ cum Hypophosphitibus, *N. F.*; Liquor Hypophosphitum Compositus, *N. F.*; Syrupus Hypophosphitum Compositus, *N. F.*

POTASSII IODIDUM. U. S., Br.

POTASSIUM IODIDE Pot. Iod.

"Potassium Iodide, when dried to constant weight at 100° C., contains not less than 99 per cent. of KI." *U. S.* "Potassium Iodide may be obtained by adding a slight excess of iodine to a strong solution of potassium hydroxide, evaporating to dryness, fusing with charcoal, and purifying by crystallisation. When dried at 100° C. it contains not less than 99 per cent. of pure potassium iodide, KI." *Br.*

Iodide of Potassium; Potassii Hydriodas; Kali Hydriodicum, Ioduretum Potassicum, s. Kalicum; Joduretum Kalii, Iodure de Potassium, *Fr. Cod.;* **Kalium Jodatum,** *P. G.;* **Kaliumjodid, Jodkalium,** *G.;* Joduro di potassio, *It.;* **Yoduro potasico,** *Sp.*

No process is given in the U. S. or Br. Pharmacopœias. That of the U. S. P., 1870, did not differ essentially from the British, 1885. (See *U. S. Dispensatory,* 19th edition, page 1005.)

An aqueous solution of potassium hydroxide is treated with iodine in slight excess which causes the formation of potassium iodide and potassium iodate.

$$6KOH + 3I_2 = 5KI + KIO_3 + 3H_2O$$

By evaporating the solution to dryness the mixed salts are obtained, and, if the dry mass be exposed to a red heat, the iodate will be converted into iodide; charcoal facilitates the deoxidation of the iodate.

$$KIO_3 + 3C = KI + 3CO$$

This being accomplished by a dull red heat, the potassium iodide is dissolved out of the mass, and the solution is set aside to crystallize.

In the older processes the first step was to form ferrous iodide in solution, to decompose it by potassium carbonate, which gave rise to potassium iodide in solution, and a precipitate of ferrous carbonate. This method is analogous to that described under potassium bromide, which see. According to the method of E. Sonstadt, potassium iodide is prepared directly from the mother liquors of kelp by converting the alkaline iodides into iodates by means of chlorine or potassium permanganate, precipitating the iodic acid by a soluble barium salt, heating the precipitate with solution of potassium sulphate, evaporating the resulting potassium iodate solution to dryness, and crystallizing from its solution the potassium iodide thus obtained. (*Chem. News,* xxvi, 182.)

Large quantities are now manufactured from the cuprous iodide coming from the South American sodium nitrate works. The cuprous iodide is suspended in water acidified with hydrochloric acid, and a stream of hydrogen sulphide gas let in, whereby hydrogen iodide enters into solution. This solution is filtered, neutralized with potassium carbonate, and evaporated to crystallization.

$$CuI_2 + H_2S = CuS + 2HI$$
$$2HI + K_2CO_3 = 2KI + H_2O + CO_2$$

Description and Physical Properties.—"Cubical crystals, either transparent and colorless or more or less opaque and white, or a white, granular powder. It is stable in dry air, but slightly deliquescent in moist air. One Gm. of Potassium Iodide is soluble in 0.7 cc. of water, in 22 cc. of alcohol, and in 2 cc. of glycerin, at 25° C. One Gm. is soluble in 0.5 cc. of boiling water and in 8 cc. of boiling alcohol. An aqueous solution of the salt (1 in 20) is neutral or slightly alkaline to litmus paper. When heated, Potassium Iodide decrepitates. At a low red heat (about 684° C.) it fuses and at a bright red heat (about 720° C.) is volatilized without decomposition.

"An aqueous solution of Potassium Iodide responds to the reactions for potassium, and for iodides.

"Dissolve 1 Gm. of the salt in 10 cc. of distilled water and add 0.1 cc. of tenth-normal sulphuric acid: no color is produced by the subsequent addition of a drop phenolphthalein T.S. (*alkali*). Dissolve 0.5 Gm. of the salt in 10 cc. of distilled water, which has been previously boiled and cooled, and add two drops of diluted sulphuric acid: no distinct yellow color appears within half a minute (*iodate*), and no turbidity occurs (*thiosulphate*). Add 5 cc. of sodium hydroxide T.S. and about 0.2 Gm. of aluminum wire to a solution of 1 Gm. of Potassium Iodide in 5 cc. of distilled water contained in a test tube of about 40 cc. capacity. Insert a pledget of purified cotton in the upper portion of the test tube and place a piece of moistened red litmus paper over its mouth: on heating the tube and contents upon a water bath for fifteen minutes, no blue coloration of the paper is discernible (*nitrate or nitrite*). Acidulate slightly 10 cc. of an aqueous solution of the salt (1 in 20) with hydrochloric acid: it is not rendered turbid by the addition of 1 cc. of potassium sulphate T.S. (*barium*). A 2 Gm. portion of the salt shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid. Heat gently 5 cc. of an aqueous solution of the salt (1 in 10) with one drop of ferrous sulphate T.S. and 0.5 cc. of sodium hydroxide T.S.: no blue color appears after acidulating the mixture with hydrochloric acid (*cyanide*). An aqueous solution of the salt meets the requirements of the test for *heavy metals.*

"**Assay.**—Dry the salt to constant weight at 100° C. and proceed as directed under the assay for iodides. Each cc. of tenth-normal silver nitrate corresponds to 0.01660 Gm. of KI. Each Gm. of Potassium Iodide, previously dried, corresponds to not less than 59.6 cc. and not more than 61.0 cc. of tenth-normal silver nitrate.

"Preserve in well-closed containers." *U. S.*

"Colorless, generally opaque, cubic crystals. Taste saline, slightly bitter. Soluble in less than 1 part of *water,* and in 12 parts of *alcohol* (90 per cent.). Usually slightly alkaline to *litmus.* Yields the *reactions* characteristic of potassium and of iodides. Loses not more than 1 per cent. of its weight when dried at 100° C.; 0.5 gramme of this dried salt requires for complete precipitation not less than 29.8 nor more than 30.5 millilitres of *N/10 solution of silver nitrate.* Yields no characteristic *reactions* for copper, iron, aluminium, calcium, magnesium, bromates, cyanides, or nitrates, and not more than the slightest reactions for bromides, iodates, carbonates, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

R. Van Vorst has pointed out (*Ph. Ztg.*, 1914, p. 342) that the red spots seen sometimes upon crystals of potassium iodide are not always due to free iodine, as, in a case which he investigated, the salt dissolved to a colorless solution leaving an insoluble red precipitate, which upon closer investigation was found to be the cell structure of a microscopic form of mold.

Its solution is quickly decomposed by the addition of a few drops of sulphuric acid, hydriodic acid being generated, which speedily undergoes decomposition, with evolution of iodine, and, if starch be added after the lapse of a few minutes, a blue color will be produced. The starch test will not give the characteristic blue color immediately, if added simultaneously with the acid, unless the potassium iodide contains potassium iodate, which impurity causes an immediate liberation of iodine. The blue color being produced by the starch and acid, if simultaneously added, is, therefore, a sign of impurity. Hydrogen dioxide solution may be used in this test as it causes the liberation of free iodine from soluble iodides. A very delicate test for potassium iodide and other soluble iodides is that of Grange. It consists in pouring a little of the liquid to be examined into a test tube, adding a few drops of solution of starch, and passing through the mixture a few bubbles of fuming nitrous acid. The liquid immediately assumes a pale rose color, inclining to violet, if containing 1-200,000th of its weight of the iodide, and a bright blue color if 1-100,000th is present.

Years ago Payen noticed a curious effect produced by potassium iodide. In saturated solution, this salt causes in starch added to it an enlargement of its granules to twenty-five or thirty times their original volume, dissolving the interior substance of the granules, and enormously distending the exterior layer. Potassium bromide produces the same effect, but the alkaline chlorides cause neither the enlargement referred to, nor a solution of the amylaceous substance, and if the saturated solution of the iodide be diluted with three and a half volumes of water or more, it is inert in reference to starch in the cold.

It was first pointed out by Loew (*A. J. P.*, xlii, 80), and afterwards confirmed by various chemists that iodine is liberated from a solution of potassium iodide by direct sunlight; the more concentrated the solution the more energetic is the action. This effect appears to be due to the liberation of hydriodic acid, which is decomposed by light, and, it is stated, will not occur in alkaline solutions.

Melsens has noticed another very important fact in relation to the operation of potassium iodide. When this salt and potassium chlorate are mixed in solution, no change takes place at ordinary temperatures; but if a certain amount of a mineral acid be added to the solution of the mixed salts, a reaction occurs, attended with the escape of iodine, and evidences are presented of the existence of iodic acid in the solution. He ascertained by experiments on dogs that neither of these salts, if given separately and at different times, produces an evil effect, while if given together, so as to be in the system at the same time, they act as a poison, and may cause death in a few days. Melsens ascribed the result to the production of potassium iodate, which he has shown to be a poisonous salt. (*A. J. P.*, Nov., 1866, p. 521.) With certain alkaloids potassium iodide is incompatible, partly on account of the fact that it is permitted to contain a little alkaline carbonate to retard discoloration, and partly because with some alkaloids insoluble iodides are formed, and fatal results have been caused by the strychnine iodide crystallizing out of a prescription, so that the whole of it was taken at a single dose. It is customary for pharmacists to place a "shake-well" label upon the bottle containing such prescriptions in order to ensure uniform dosage of the active principle.

Potassium iodide is also *incompatible* with calomel, mercurous and mercuric salts, and metallic mercury. With nitrous ether potassium iodide reacts, yielding, among other products, ethyl iodide and a little ordinary ether. At ordinary temperatures potassium iodide is slowly decomposed, with evolution of iodine, by ammonium nitrate or boric acid, and at high temperatures, in a glass test tube, with escape of violet vapors, not only by the two substances just named, but also by ammonium sulphate, oxalate, carbonate, and chloride, sodium sulphate, phosphate, nitrate and borate, potassium and magnesium sulphates, and calcium nitrate.

Uses.—The general therapeutic properties of potassium iodide are the same as those of other iodides. (See *Iodum.*) It is useful especially in *syphilis, chronic fibrinous inflammations,* and certain *metallic poisons.* With corrosive sublimate it forms a soluble potassio-mercuric iodide which is the basis of the so-called "mixed treatment" for *syphilis.* When it is administered in large repeated doses it produces evidences of systemic affection, known as *iodism.* The most usual indication of its constitutional action is a pain over the brow, with coryza; in some cases a mild ptyalism, with fetor of the breath and slight swelling of the gums, is produced. In a number of cases it causes an eruption, sometimes simply of macula, but usually of acne and occasionally bullous or hemorrhagic. In unusual conditions of the system these skin affections may become very severe and ulcerations result. Knowles (*J. A. M. A.*, 1910, lv, p. 100) gives an extensive bibliography of the literature of this subject.

The dose of potassium iodide varies enormously, many persons will show symptoms of iodism from twenty grains (1.3 Gm.) a day, but other cases as much as one or two drachms (3.9–7.7 Gm.) have been given three times a day without toxic symptoms. Many clinicians believe that syphilitics are abnormally tolerant of the drug.

Potassium iodide is eliminated through the urine unchanged and may be detected by acidulating with nitric acid which causes the liberation of the free iodine, and by testing with starch.

Potassium iodide is employed as an external application in the form of ointment, either alone or mixed with iodine. (See *Unguentum Potassii Iodidi* and *Unguentum Iodi.*)

Dose, five to twenty grains (0.32–1.3 Gm.); in special cases much larger doses may be exhibited.

POTASSII NITRAS. U. S., Br.

POTASSIUM NITRATE Pot. Nit. [Saltpeter]

"Potassium Nitrate, when dried to constant weight at 100° C., contains not less than 99 per cent of KNO_3." *U. S.* "Potassium Nitrate, KNO_3, may be obtained by the interaction of sodium nitrate and potassium chloride." *Br.*

Potassæ Nitras; Nitrium Depuratum, Sal Petræ, s. Nitri, Nitras Potassicus, s. Kalicus; Nitrate of Potash, Nitre; Nitrate de Potasse, Azotate de Potasse, Saltpêtre, *Fr.;* Kalium Nitricum, *P. G.;* Kalium-nitrat, Saltpetersaures Kali, Kalisaltpeter, *G.;* Nitrato di potassio, Nitro, *It.;* Nitrato potasico, *Sp.*

Potassium nitrate, or *niter,* is both a natural and an artificial product. It occurs in many countries, existing in the soil, on which it forms a saline efflorescence, in the fissures of calcareous rocks, and in caves. It has been found in different parts of Europe, in South Africa, in Egypt, and in Chili, Peru and Bolivia, but the country in which it has been most largely produced is India, in the districts of Bengal and Bombay, and in the island of Ceylon. In the United States it has been found in caverns situated in limestone rock, called saltpeter caves, where it is associated with calcium nitrate. Considerable deposits also occur in San Bernadino County in California, but have not been developed as yet. At present it is chiefly obtained from deposits in India, or by acting on sodium nitrate with potassium chloride, $NaNO_3 + KCl = KNO_3 + NaCl$.

Potassium nitrate exists also in the vegetable kingdom, having been found in tobacco, borage, bugloss, sunflower, etc. The artificial sources are certain mixtures of animal and vegetable substances with wood ashes and calcareous matter, called niter-beds.

In India the saline earth, which sometimes contains over 25 per cent. of KNO_3 and usually above 3 per cent. is lixiviated in large mud filters lined with stiff clay, and furnished with false bottoms of bamboo, covered with grass mats, on which wood ashes are laid. The filters being then filled with the saline earth, water is added, and the solution filters through the wood ashes, with the effect of converting the calcium nitrate present into potassium nitrate. The solution obtained is evaporated in earthen pots, filtered, and set aside to crystallize. The impure potassium nitrate thus obtained contains from 45 to 70 per cent. of the pure salt. It is redissolved and crystallized, and thrown into commerce under the name of crude saltpeter. Besides the niter obtained in India by the filtration of the soil deposited during the overflow of the Ganges, much of the crude salt is procured, in the northwestern provinces of Hindostan, from the saline incrustations formed in and around the mud walls surrounding the dwellings of the natives. The scrapings from these sources are lixiviated, and the impure solution allowed to evaporate in shallow pans exposed to the sun. The impure niter extracted from the earthy matters crystallizes out, while from 1 to 9 per cent. of sodium chloride remains in the mother liquor, and is recovered by evaporation. The mother liquors from these crude extraction processes are used for lixiviating fresh portions of soil.

Within recent years potassium nitrate has been most largely manufactured from the native potassium chloride of Stassfurt and the native sodium nitrate of Chili, two cheap and abundant crude materials, which by their reaction yield potassium nitrate. (See reaction on previous page.) This so-called "conversion saltpeter" can be produced 99.9 per cent. pure nitrate.

Artificial niter beds are not as frequently employed as a source of this salt as formerly. They are formed of animal and vegetable remains, together with ashes and calcareous earth, which are mixed up with a portion of loose soil and placed under sheds, to shelter the mixture from the rain, while the sides are left open, to admit the free access of air. The mixture is disposed in little heaps, which are frequently turned over with a spade, and sprinkled with urine, as a substance containing a large quantity of nitrogen. At the end of two or three years the nitrogen is converted into nitric acid, and this, by reacting with the potassium compounds existing in the vegetable remains, forms niter. When the contents of the bed contain about four ounces of the salt for every cubic foot of the materials, they are deemed fit to be lixiviated. The extraction and purification is similar to that used in India for purifying the natural salt.

The continuous formation of niter in niter earths and in artificial niter beds results from the oxidation of the nitrogen of ammonia, thus generating nitric acid, the formation of which is facilitated by the presence of alkaline and earthy bases, with which the acid unites, but in reality depends upon the presence of nitrifying micro-organisms (*Bacillus nitrificans*); nitrification is, therefore, not a simple chemical oxidation process, as was at one time supposed. The ammonia is derived, for the most part, from the protein of the organic remains in the niter earths. There is first formed calcium nitrate which then reacts with the potassium carbonate of the wood ashes to form potassium nitrate, according to the following reaction:

$$Ca(NO_3)_2 + K_2CO_3 = 2KNO_3 + CaCO_3$$

According to Schoenbein, whose statement has been confirmed by Goppelsröder, the formation of the nitric acid is always preceded by that of nitrous acid.

Potassium nitrate, as first obtained, either from natural or from artificial sources, is called in commerce crude saltpeter, and requires to be purified before it can be used in medicine or in most of the arts. Like the process of purifying crude argol in making cream of tartar it consists only in dissolving, clarifying the hot solution and crystallizing. (For details, see *U. S. D.*, 20th ed., p. 907.)

Description and Physical Properties.—"Colorless, transparent, six-sided rhombic prisms, or a white, crystalline powder. It is odorless, has a saline taste, and produces a cooling sensation in the mouth. It is slightly hygroscopic in moist air. One Gm. of Potassium Nitrate is soluble in 2.8 cc. of water, and in 620 cc. of alcohol, at 25° C. One Gm. is soluble in 0.5 cc. of boiling water. It is soluble in glycerin. When strongly heated, the salt melts without decomposition. At higher temperatures it evolves oxygen and is partly reduced to nitrite. When Potassium Nitrate is heated with charcoal, the mixture deflagrates.

"An aqueous solution of the salt (1 in 10) responds to the reactions for potassium and for nitrates.

"An aqueous solution of Potassium Nitrate (1 in 10) is neutral to litmus paper. An aqueous solution of Potassium Nitrate meets the requirements of the test for *heavy metals.* No yellow color appears when 0.1 Gm. of the dry salt is sprinkled upon 1 cc. of concentrated sulphuric acid (*chlorate*).

"**Assay.**—Dry about 0.4 Gm. of Potassium Nitrate to constant weight at 100° C., weigh accurately, dissolve it in 10 cc. of hydrochloric acid in a small porcelain dish, and evaporate the solution to dryness on a water bath. Dissolve the residue in 10 cc. of hydrochloric acid, and again evaporate to dryness on a water bath, continuing the heat until the residue, when redissolved in distilled water, is neutral to litmus paper. Transfer the residue with the aid of 25 cc. of distilled water to a flask, and proceed as directed under the assay for chlorides, deducting from the amount of tenth-normal silver nitrate consumed the amount which would be consumed by the chlorides present in an equivalent weight of the salt originally taken, and previously determined by taking about 2 Gm. of the salt, accurately weighed, and proceeding as directed under the assay for chlorides. Each cc. of tenth-normal silver nitrate corresponds to 0.01011 Gm. of KNO_3.

"Preserve in well-closed containers." *U. S.*

"White crystalline masses, or colorless fragments of six-sided rhombic prisms. Taste cool, saline. Soluble in 4 parts of *water.* Yields the *reactions* characteristic of potassium and of nitrates. Yields no characteristic *reactions* for copper, iron, aluminium, zinc, calcium, magnesium, sodium, ammonium, chlorides, iodides, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

It is devoid of water of crystallization, but is apt to contain a portion of liquid mechanically lodged within the substance of the crystals. This is particularly the case with the large crystals, and, according to Berzelius, is a source of impurity, as the liquid in question is a portion of the mother water in which they were formed. It is on this account that Berzelius recommends that the solution of the purified salt should be stirred during crystallization, so as to cause it to shoot into small crystals. The fused mass, when cast in moulds, or formed into little circular cakes, constitutes that form of niter found in commerce under the name of *crystal mineral* or *sal prunelle.* If the heat is increased, the salt is decomposed, evolves pure oxygen, and is reduced to the state of nitrite, which, in powder emits orange-colored fumes of hyponitric acid, and nitrous oxide on the addition of sulphuric acid. Upon a further continuance of the heat, the nitrous acid itself is decomposed, and a large additional quantity of oxygen is evolved, contaminated, however, with more or less nitrogen. On account of the large proportion of oxygen which it affords, niter increases the combustion of many substances in a remarkable degree. When thrown on burning coal, it deflagrates with bright scintillations. In the reaction of niter with charcoal, carbon dioxide is produced, and never carbon monoxide, and the nitric acid is variously decomposed into nitrous oxide, nitrogen dioxide, or nitrogen, according to the proportion of the charcoal and to the heat employed.

Uses.—Potassium nitrate, when in sufficient concentration, acts upon a raw surface or a mucous membrane as a violent irritant, and taken internally in concentrated form produces violent burning pain, vomiting, purging, and other evidences of gastro-enteritis, which may end in collapse and death. Inflammation and ulceration of the mucous membrane are commonly found at the autopsies.

As a therapeutic agent potassium nitrate is of very little importance. Its former use as a diuretic and in *rheumatism* has passed into a well deserved desuetude. Locally, it has been used in the place of potassium chlorate in *stomatitis* and *angina* but is even less efficacious than that feeble remedy.

In *asthma,* nitrous fumigation is often useful, performed by inhaling the fumes from burning torch paper, prepared by dipping blotting paper in a saturated solution of niter and afterwards drying it. Such paper is official in the N. F. (See *Charta Potassii Nitratis,* Part III.) Vohl has examined the vapor resulting from the burning paper thus impregnated, and found it to consist of carbon dioxide and oxide, cyanogen, ammonia, nitrogen, aqueous vapor, and potassium carbonate and nitrite, and he ascribes the beneficial results of its inhalation to the ammonia and potassium nitrite. It is habitually added to stramonium leaves in the preparation of so-called asthmatic powders, but it is used under these circumstances more for its oxidizing effect in encouraging the combustion than for its own therapeutic action.

In pharmacy, potassium nitrate was formerly employed to form crocus of antimony, to procure nitric acid, and sometimes in the preparation of spirit of nitrous ether. In chemistry it is used as an oxidizing agent.

Dose, five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Charta Potassii Nitratis, *N. F.*

POTASSII PERMANGANAS. U. S., Br.

POTASSIUM PERMANGANATE Pot. Permang.

"Potassium Permanganate, when dried to constant weight over sulphuric acid, contains not less than 99 per cent. of $KMnO_4$. *Great caution should be observed in handling it, as dangerous explosions are liable to occur when it is brought into contact with organic or other readily oxidizable substances, either in solution or in the dry condition.*" *U. S.* "Potassium Permanganate may be obtained by the interaction of potassium chlorate, potassium hydroxide, and manganese dioxide. It contains not less than 99 per cent. of pure potassium permanganate, $KMnO_4$." *Br.*

Potassæ Permanganas; Hypermanganas Potassicus, s. Kalicus; Permanganate of Potash; Permanganate de Potasse, Caméléon Violet, *Fr.;* Kalium Hypermanganicum, *Fr. Cod.;* Kalium Permanganicum, *P. G.;* Kaliumpermanganat Chamäleon, Uebermangansaures Kali, *G.;* Permanganato di potassio, *It.;* Permanganato pota, *Sp.*

The British Pharmacopœia 1885 furnished a detailed process for this salt. (See *U. S. D.,* 19th edition, page 1013.) This process resembles that of Woehler which is employed on the large scale as follows: a mixture of potassium chlorate and manganese dioxide is added to a solution of potassium hydroxide. The potassium chlorate yields oxygen to manganese dioxide, converting it into manganic acid, which unites with the potassium hydroxide to form the manganate, potassium chloride being formed at the same time; the reaction being

$$3MnO_2 + 6KOH + KClO_3 = 3K_2MnO_4 + KCl + 3H_2O$$

When this solution is boiled, while a current of chlorine or of ozone is passed through as an oxidizing agent the green potassium manganate which is sometimes called *chameleon mineral,* is oxidized and yields potassium permanganate, according to the reaction

$$3K_2MnO_4 + O_3 + H_2O = K_2Mn_2O_8 + O_2 + 2KOH$$

Potassium permanganate has also been made by the electrolysis of the manganate, the products being permanganate, potassium hydroxide, and hydrogen. A still more interesting result of electrolysis is the production of potassium permanganate by the electrolysis of potassium hydroxide, in which the negative electrode is of porous copper oxide and the positive electrode a piece of manganese or ferro-manganese held immersed by a loop of platinum wire. A process for the complete conversion of manganate into permanganate has been patented in Germany. The crude manganate obtained in the usual way by melting manganese dioxide and alkali under access of air, is exhausted with water and a current of *ozonized* air is passed into and through the alkaline solution. The conversion of the manganate into permanganate is complete and rapid, whereas when ordinary oxygen is thus introduced the formation is slow and incomplete. (*Ph. Ztg.,* 1901, 517.)

Description and Physical Properties.—"Odorless, slender, monoclinic prisms, of a dark purple color, almost opaque by transmitted light, and of a blue, metallic luster by reflected light. It is stable in the air. One Gm. of Potassium Permanganate is soluble in 13.5 cc. of water at 25° C. One Gm. is soluble in 3.5 cc. of boiling water. It is decomposed by alcohol.

"When heated, the Potassium Permanganate decrepitates, and at about 240° C. it is decomposed, yielding oxygen, potassium manganate and manganese dioxide. An aqueous solution of the salt is of a deep violet-red color when concentrated, and of a rose color when highly diluted and responds to the reactions for permanganates, page .

"**Assay.**—Dry about 0.10 Gm. of Potassium Permanganate to constant weight over sulphuric acid, weigh accurately, and dissolve it in 25 cc. of distilled water. Mix the solution with 1 cc. of sulphuric acid and 50 cc. of tenth-normal oxalic acid, warm the mixture to about 80° C., and titrate with tenth-normal potassium permanganate. Each cc. of tenth-normal oxalic acid corresponds to 0.003161 Gm. of $KMnO_4$.

"Preserve in glass-stoppered bottles." *U. S.*

"Dark purple, slender, prismatic, iridescent crystals. Taste sweet, astringent. Soluble in 20 parts of *water.* Aqueous solution neutral to *litmus.* The crystals heated to redness decrepitate, evolve oxygen, and leave a black residue from which *water* extracts potassium hydroxide, the resulting solution yielding the *reactions* characteristic of potassium. Yields no characteristic *reactions* for lead, arsenic, iron, sodium, ammonium, chlorides, nitrates, or sulphates. 1 gramme dissolved in *water,* acidified with 5 millilitres of *diluted sulphuric acid,* and heated to about 60° C., requires for complete decolorisation not less than 31.3 millilitres of *N/1 solution of oxalic acid.*" *Br.*

If the solution be evaporated to dryness, the salt has the form of an intensely black powder. If suddenly heated, the crystals detonate, evolving oxygen, and leaving a black residue, which yields potassium hydroxide to water.

Moderately heated, the crystals are partially volatilized, giving out violet vapors of a disagreeable metallic odor. The salt, in consequence of the facility with which it parts with oxygen, is one of the most powerful oxidizing agents known. It causes the combustion of certain inflammable bodies, imparts oxygen to almost all organic substances, and in chemistry is employed to bring various compounds to a higher degree of oxidation. The readiness with which it yields oxygen in the nascent state is sufficient to account for its oxidizing power. It may be kept indefinitely if pure, and carefully secured from contact with organic substances, or other decomposing agents.

H. B. Condy many years ago introduced a permanganate disinfectant, which is commonly called *Condy's Fluid.* This consists of a crude sodium permanganate in solution and containing also aluminum sulphate, which is said to increase the oxidizing effect of the permanganic acid.

Uses.—Potassium permanganate was brought to the notice of the profession by Condy in 1857, who recommended it as a powerful disinfectant. The findings of bacteriologists concerning the germicidal powers of this substance have varied most extraordinarily. These discrepancies have been due not solely to variations in the susceptibility of different species of bacteria but probably in greater degree, as pointed out by Sternberg, to the difference in conditions of test. In the absence of organic matter it is distinctly superior in power to phenol but it is so readily decomposed that in the presence of any considerable amount of pus or other albuminous matters it is almost inert. It appears to be especially poisonous towards *staphylococcus pyogenes,* Sternberg having shown that one part in 833 is sufficient to destroy these bacteria in the absence of organic matter. Because of its activity as an oxidizant it is useful as a cleanser of *wounds* and the more so because of its deodorizing properties. One great disadvantage is its strong powers of staining the skin, clothes, etc. The stain may be removed with oxalic acid in places where the use of this substance is permissible. It is used in the treatment of *fetid ulcers, hospital gangrene, abscesses, carbuncles,* and *wounds* of all kinds, of fetid discharges from the mucous membrane, as in *ozena, otorrhea, gonorrhea,* and *leucorrhea,* and of *diphtheritic affections;* and it has proved serviceable even in *cancerous ulcers.* As a local stimulant it has also been used in *chronic* and *indolent ulcers.* In all these cases it is applied to the diseased surface in solutions of various strengths, according to the effect desired. In concentrated solution it is capable of acting as a caustic and therefore requires caution. With the view to its caustic action, it may be sprinkled on the diseased surface by means of a pepper-box, or applied in saturated solution. It has been highly recommended as an external application, to prevent pitting and septic absorption, in *small-pox* by Balfour (*Tropical Med. and Hyg.,* 1921, xxiv, 37).

As an external disinfectant it is generally employed in strengths of from 1 to 5 per cent., but for application to mucous surfaces its strength must be greatly reduced and may be employed in strengths of from 1 part in 2000 and upwards.

Probably through its oxidizing influence potassium permanganate destroys many poisons and is a useful chemical antidote in *morphine* and *strychnine poisoning,* but especially in *snake bite.* The use of potassium permanganate as an antidote to snake poison was first suggested by Fayrer in 1869 and confirmed by Lauder Brunton in 1878. Today, potassium permanganate is generally considered as the most valuable single drug that we possess against snake bite. As its action is a chemical one—that is, destruction of the poison—it is purely local in nature and the antidote must, therefore, be brought in contact with the poison by introducing into the same area. Two methods of accomplishing this have been employed. Rogers (*Indian Med. Gaz.,* 1912, xlvii) recommended incision of the wound and rubbing in crystals of the permanganate. He devised a special lancet to be carried by those travelling in snake infested districts, the hollow handle of which contained the crystals of the permanganate. Bannerman (*Indian Journ. Med. Research,* 1913), however, concluded that the hypodermic injection, directly into the area bitten, of a 5 per cent. solution of potassium permanganate was more efficient; this solution, however, produces extensive sloughing. Widenmann (*Cb. B.,* 1915) found that a 1 per cent. solution, if injected immediately and rubbed into the perivascular lymph spaces, would save rabbits from double the ordinary lethal dose of venom. In human medicine it is generally injected hypodermically into the region of the bite in strengths of from 1 to 2 per cent.

It is evident that like any other chemical antidote potassium permanganate must come in direct contact with the poison—whether alkaloid or venom—and since it is immediately decomposed by the tissues of the body, contrary to the statements occasionally made, it is useless after the absorption of the drug.

It is also recommended as a local hemostatic. Voerner (*M. M. W.,* 1905) recommends a mixture of one part of infusorial earth and two parts of potassium permanganate made up into a paste with one-third their bulk of petrolatum. Internally it was at one time employed in various *infectious diseases,* but its use for this purpose has entirely ceased. It is occasionally administered in *atonic amenorrhea.*

In overdose potassium permanganate may give rise to serious poisoning. Rubin and Dorner (*D. A. K. M.,* 1910, xcviii, p. 267) report a fatal case in which an unknown quantity was taken with suicidal intent. The symptoms were violent vomiting, profuse salivation with brownish masses of mucus, rapid respiration, albuminuria, and death fifty hours later. At autopsy there was found a bronchial pneumonia and punctiform hemorrhages in the pericardium.

Dose, from one to two grains (0.065–0.13 Gm.).

Off. Prep.—Liquor Potassii Permanganatis, *Br.*

POTASSII SULPHAS. N. F., Br.

POTASSIUM SULPHATE Pot. Sulph.

"Potassium Sulphate contains, when dried to constant weight at 100° C., not less than 99 per cent. of K_2SO_4 (174.26)." *N. F.*

"Potassium Sulphate may be obtained by the interaction of sulphuric acid and potassium chloride or certain other potassium salts. It contains not less than 99 per cent. of pure potassium sulphate, K_2SO_4." *Br.*

Potassæ Sulphas; Sulfas Potassicus, s. Kalicus, Tartarum Vitriolatum, Arcanum Duplicatum, Sal Duobus, Sal Polychrestum Glaseri; Sulphate of Potash, Vitriolated Tartar; Sulfate de Potasse, Potasse vitriolée, *Fr.;* Kalium Sulphuricum, *P. G.;* Kaliumsulfat, Schwefelsaures Kali, *G.;* Solfato di Potassio, *It.;* Sulfato potasico, *Sp.*

Potassium sulphate is naturally present in sea water, in some mineral waters, and in some other naturally occurring sources.

Several chemical processes give rise to potassium sulphate as a secondary product. Thus, it is produced in the distillation of nitric acid from a mixture of potassium nitrate and sulphuric acid; in the decomposition of magnesium sulphate by potassium carbonate; in one of the processes for preparing magnesium carbonate; in the manufacture of sulphuric acid; in the manufacture of potassium dichromate; and in the decomposition of potassium tartrate by calcium sulphate. The *kainite* of the Stassfurt salt beds is a native double potassium and magnesium sulphate, combined with magnesium chloride, and the *schœnite,* a double potassium and magnesium sulphate, with 6 molecules of water. To obtain potassium sulphate, the former mineral is exposed to the air; it deliquesces, and as soon as the soluble magnesium chloride has been run off, the remaining salt is partially decomposed by boiling water, so that on cooling the difficultly soluble sulphate separates out.

Properties.—As officially described it is in "colorless, hard rhombic prisms terminated by six-sided pyramids. Taste saline, slightly bitter. Decrepitates strongly when heated. Soluble in 10 parts of *water;* insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of potassium and of sulphates. 1 gramme dissolved in water acidified with *hydrochloric acid* gives, with *solution of barium chloride,* a white precipitate, which, when washed and dried, weighs not less than 1.326 grammes. Yields no characteristic *reactions* for copper, iron, calcium, magnesium, sodium, ammonium, or nitrates, and not more than the slightest *reactions* for chlorides. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million. Aqueous solution neutral to *litmus* (absence of acid potassium sulphate)." *Br.*

Description and Physical Properties.—"Potassium Sulphate occurs as hard, colorless, translucent, six-sided, rhombic prisms terminated by pyramids, or as a white powder; permanent in the air. Odorless; taste saline, somewhat bitter. One Gm. dissolves in 10 cc. of water at 25° C., and in 4 cc. of boiling water; insoluble in alcohol.

"When heated the crystals decrepitate. At a bright red heat the salt fuses, and at a white heat partial decomposition occurs. An aqueous solution of the salt (1 in 20) is neutral to litmus. A saturated aqueous solution of the salt yields a white, crystalline precipitate with an excess of sodium bitartrate T.S. An aqueous solution of the salt (1 in 20) yields with barium chloride T.S. a heavy white precipitate, insoluble in hydrochloric acid.

"Separate portions of 10 cc. of the aqueous solution of the salt (1 in 20) made slightly alkaline with ammonia, are not rendered turbid within one minute by the addition of ammonium oxalate T.S. or of sodium phosphate T.S. (*calcium or magnesium*). An aqueous solution of Potassium Sulphate does not respond to the Test for heavy metals. An aqueous solution of the salt meets the requirement of the Test for arsenic.

"**Assay.**—Dissolve about 0.6 Gm. of Potassium Sulphate, previously dried to constant weight at 100° C. and accurately weighed, in 200 cc. of distilled water, acidulate the solution with hydrochloric acid and heat it to boiling. Gradually add an excess of barium chloride T.S., and heat for thirty minutes on a water-bath; collect the precipitate of barium sulphate on a filter and wash it with distilled water until silver nitrate T.S. fails to produce an opalescence in 2 cc. of the filtrate, previously acidulated with nitric acid. Dry the precipitate, ignite and weigh the residue. Each Gm. of Potassium Sulphate corresponds to not less than 1.326 Gm. of $BaSO_4$." *N. F.*

For the mode of preparing and using *Sal Polychrestum, Potassii Sulphas cum Sulphure,* or *Sulphate of Potassa with Sulphur,* and for a discussion of *Plate Sulphate of Potassa,* see *U. S. D.,* 15th ed., p. 1187.

Uses.—Potassium sulphate is a mild purgative, operating usually without heat, pain, or other symptom of irritation. In small doses, of from twenty grains to half a drachm (1.3–2.0 Gm.), it operates as an aperient; in large doses, of four or five drachms (15.5–20 Gm.), it acts slowly as a purge, but because of its irritant action is not to be recommended. Potassium sulphate is a powerful irritant in excessive doses, and capable of producing fatal poisoning; an ounce and a half (46.5 Gm.) of it are said to have caused death. It is, like the nitrate and the chlorate, more dangerous when not given in sufficiently dilute solution. (See *Am. J. M. S.*, N. S., vii, 88.)

Dose, twenty grains to two drachms (1.3–7.7 Gm.).

POTASSII TARTRAS. Br.

POTASSIUM TARTRATE

"Potassium Tartrate may be obtained by neutralizing Acid Potassium Tartrate with potassium carbonate. It contains not less than 99 per cent. of pure potassium tartrate, $(K_2C_4H_4O_6)_2H_2O$." *Br.*

Potassæ Tartras; Tartras Potassicus, s. Kalicus; Tartarus Tartarisatus, Tartarus Solubilis; Tartrate of Potash; Soluble Tartar; Tartrate de Potasse neutre, *Fr. Cod.;* Tartre soluble, Sel végétal, *Fr.;* Kalium Tartaricum, *P. G.;* Kaliumtartrat, *G.;* Tartrato neutro di potassio, *It.;* Tartrato potasico neutro, *Sp.*

This salt was dropped at the 1890 revision of the U. S. Pharmacopœia; it is retained in the 1914 revision of the British authority.

In the U. S. 1870 process the excess of acid in the bitartrate is neutralized by potassium carbonate, the carbon dioxide is liberated with effervescence, and the neutral potassium tartrate is formed. Iron vessels should not be used in the process, as that metal is apt to discolor the salt.

Potassium tartrate is sometimes made in the process for preparing tartaric acid. When thus obtained, the excess of acid of the bitartrate is neutralized by means of calcium carbonate. This generates an insoluble calcium tartrate, and leaves the neutral tartrate in solution, from which it may be obtained by evaporation and crystallization. (See *Acidum Tartaricum.*)

Properties.—Potassium tartrate is officially described in the Br. Ph. 1914 as in "small, colorless, four or six-sided prisms. Taste saline, cooling. Soluble in 1 part of *water.* Yields the *reactions* characteristic of potassium and of tartrates. 1 gramme, heated to redness till gases cease to be evolved, leaves an alkaline residue which, when treated with *water,* filtered, and well washed, yields a clear solution requiring for neutralisation not less than 16.8 millilitres of *N/2 solution of sulphuric acid.* Yields no characteristic *reactions* for copper, or iron, and not more than the slightest *reactions* for calcium, magnesium, sodium, chlorides, or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 2 parts per million. Aqueous solution neutral to *litmus* (absence of acid potassium tartrate)." *Br.*

Uses.—Potassium tartrate is a mild, cooling purgative, operating, like most of the neutral salts, without much pain, and producing watery stools. It is applicable to *febrile diseases,* and is occasionally combined with senna, the griping effects of which it has a tendency to obviate.

Dose, from one to four drachms (4–15 Gm.).

POTASSIUM

POTASSIUM

Potassium, *Fr.;* Kalium, Kalimetall, *G.;* Potassio, *It.;* Potasico, *Sp.*

Potassium is a metal discovered in 1807 by H. Davy, who obtained it by decomposing fused potassium hydroxide by a voltaic current. It was afterwards procured in larger quantity by Gay-Lussac and Thénard, by bringing the fused alkali in contact with white-hot iron, which attracted the oxygen and set free the metal. The process of Brunner, as modified by Wöhler, consists in decomposing potassium carbonate, mixed with charcoal. The mixture of carbonate and charcoal is obtained by heating cream of tartar to redness in a covered crucible. Castner has also prepared it by the process invented by him for the manufacture of metallic sodium by electrolyzing potassium chloride. It has recently been prepared at low cost by heating a mixture of potassium fluoride or potassium fluosilicate with powdered metallic aluminum.

Metallic potassium may be purified by redistillation and pressing it through straining cloths while in the melted condition. (For commercial sources of potassium salts, see under *Potassii Carbonas.*)

Potassium is solid, softer and more ductile than wax, easily cut with a knife, and of a silver-white color. A newly-cut surface is brilliant, but the metal quickly tarnishes by combining with the oxygen of the air, and assumes the appearance of lead. It possesses a remarkably strong affinity for oxygen, and is capable of taking that element from almost every other substance. On account of this property it must be kept submerged in pure liquid hydrocarbons, such as the petroleum distillates. On the same account, when exposed with a freshly cut surface to the air, it becomes luminous through a slow combustion, like phosphorus, in the dark. Its sp. gr. is 0.865, melting point 58° C., atomic weight 38.86, and symbol K. It volatilizes at about 720° C. with the production of greenish vapors. When thrown upon water it floats, takes fire, and burns with a rose-colored flame, combining with oxygen, and generating potassium hydroxide which dissolves in the water. It forms numerous combinations, uniting with most of the non-metallic elements, and with several of the metals. It combines in three proportions with oxygen, forming a suboxide (K_4O) and a monoxide (K_2O) of a gray color, and a tetroxide (K_2O_4) of a yellowish-brown color.

Uses.—Although elemental potassium is not used in medicine it enters into so large a number of medicinal salts and so greatly modifies the action of some of them, that the effects of the potassium ion deserve a separate word of consideration. While the presence of a certain amount of potassium in the blood is essential for vital activity, a very slight increase in its percentage has a deleterious influence on many organs. The injection of a potassium salt into the circulation weakens the contractile power of all muscle fiber but affects especially the heart and blood vessels. It also exercises a marked depressant action upon the central nervous system, including the spinal cord, brain, and medulla. Although the depressant action of potassium is strong when it is injected directly into the blood stream, when taken by the mouth it exercises very little influence upon the circulation. This is due to the fact that it is excreted by the kidneys so rapidly that it cannot be absorbed in sufficient amounts through the alimentary tract to cause the accumulation of a poisonous dose in the blood. When the kidneys, however, are diseased it is probable that a poisonous dose of the ion could be absorbed from the intestines, and therefore while the potassium salts can be used with great liberality in healthy persons, when there is disease of the kidneys some caution is necessary in their employment. During the passage of the potassium through the system it appears to exercise a marked effect upon the metabolism. Not only is there an increase in the total solid matters of the urine, but apparently a disproportionate increase in the quantity of urea. This has led to the opinion that the increased elimination is not simply the result of its diuretic action, but betokens a more complete oxidation in the system. Because of this effect the potassium salts are generally preferred in cases of deficient combustion, especially that group of disorders known as *lithemia*.

PROCAINÆ HYDROCHLORIDUM. U. S.

PROCAINE HYDROCHLORIDE Procain. Hydrochl.

"Para-amino-benzoyl-diethylaminoethanol hydrochloride $[NH_2(C_6H_4CO)OC_2H_4N(C_2H_5)_2.HCl]$." *U. S.*

Ethocaine; Novocaine; Syncaine; Kerocaine.

Procaine may be prepared in several ways. All of the methods are difficult and involve the preparation of ethylene chlorhydrine, $ClCH_2\text{-}CH_2OH$; and diethylamine, $(CH_3CH_2)_2NH$. To make novocaine, ethylenechlorhydrine is heated with paranitrobenzoyl chloride and the resulting chlor-ethyl paranitrobenzoic ester is heated under pressure at 120° C. with diethylamine for twenty-four hours. This produces the diethylaminoethyl ester of paranitrobenzoic acid which is subsequently reduced with tin and hydrochloric acid to produce novocaine.

In another method ethylenechlorhydrine is condensed with diethylamine to form chlorethyldiethylamine which is then heated with sodium paraminobenzoate to form novocaine base. In still another process paraminobenzoic acid is condensed with ethylene chlorhydrine by heating to 100° C. in the presence of sulphuric acid. The resulting compound is then heated with diethylamine in a sealed tube to form novocaine.

Description and Physical Properties.—"Small, colorless crystals or a white, crystalline powder. It is odorless, and is stable in the air. One Gm. of Procaine Hydrochloride is soluble in 0.6 cc. of water and in 30 cc. of alcohol, at 25° C. It is slightly soluble in chloroform, and almost insoluble in ether.

"Procaine Hydrochloride melts between 153° and 156° C. An aqueous solution of Procaine Hydrochloride (1 in 10) yields precipitates with gold chloride T.S., iodine T.S., mercuric potassium iodide T.S., and picric acid T.S. An aqueous solution of Procaine Hydrochloride (1 in 10) remains unchanged upon the addition of a solution of sodium bicarbonate, but with sodium hydroxide T.S. or sodium carbonate T.S., a colorless, oily precipitate is produced, which becomes crystalline on standing. Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 20) a white precipitate insoluble in nitric acid, but soluble in ammonia water. Dissolve 0.1 Gm. of Procaine Hydrochloride in 5 cc. of distilled water, add 2 drops each of hydrochloric acid and solution of sodium nitrite (1 in 10), and then a solution of 0.2 Gm. of betanaphthol in a mixture of 3 cc. of sodium hydroxide T.S. and 7 cc. of distilled water. A scarlet-red precipitate is produced (*difference from phenacaine* which yields a white precipitate). To a solution of 0.1 Gm. of Procaine Hydrochloride in 5 cc. of distilled water add 3 drops of diluted sulphuric acid, followed by 5 drops of potassium permanganate T.S.: the violet color of the latter is immediately discharged (*difference from cocaine hydrochloride*).

"Its aqueous solution (1 in 20) is neutral to litmus paper. The ash from 0.5 Gm. is negligible. A solution of 0.1 Gm. of Procaine Hydrochloride in 1 cc. of sulphuric acid is colorless or nearly colorless (*readily carbonizable substances*). An aqueous solution of Procaine Hydrochloride meets the requirements of the test for *heavy metals*." *U. S.*

Uses.—Procaine is used in medicine solely as a local anesthetic. Sollmann (*J. A. M. A.*, 1918, lxx, p. 216) has shown that in comparing the power of local anesthetics it is necessary to take into consideration the method of use; thus, procaine when applied directly to nerve trunks or when injected subcutaneously is approximately equal in power with cocaine, but when applied over mucous membranes is much inferior, being only about 1/16 as efficient as cocaine. It is, however, much less toxic than cocaine. Eggleston and Hatcher (*J. P. Ex. T.*, 1919, xiii, p. 433) found that when injected rapidly into the vein the lethal dose for the cat is about 40 milligrammes per kilo or nearly three times that of cocaine. When administered subcutaneously, because of the relatively rapid elimination of procaine, the difference is still more marked; Closson (*Jour. Mich. State Med. Soc.*, 1914, xiii, p. 587) finds that after subcutaneous injection the toxicity of procaine for the guinea pig is about 1/10 that of cocaine. Schmitz and Lowenhart (*J. P. Ex. T.*, 1924, xxiv, 167) find that the lethal dose for mice of procaine, subcutaneously, is six times that of cocaine and when tested on cats fifteen times as large. It differs from cocaine in that it does not affect the pupil nor cause local vasomotor spasm. It is practically non-irritant either to mucous membranes or to other tissues.

Clinical experience as to the value of procaine is in harmony with the scientific data. There is abundance of evidence to show that for intradermal, neural or spinal anesthesia it is a very valuable anesthetic; on the other hand, for surface anesthesia, of either the membranes of the nose or of the eye its action is generally not satisfactory. While in general its use is relatively safe, a committee of the Section Laryngology of the American Medical Association (*J. A. M. A.*, 1920, lxxv, p. 315) have collected six deaths following its use as a local anesthetic. Meeker and Frazer (*J. P. Ex. T.*, 1923, xxii, 375) are inclined to doubt whether these fatalities are properly attributed to the anesthetic. For subcutaneous anesthesia, taking into consideration both the relative safety and efficiency, it is probably unsurpassed by any anesthetic at present available. For this purpose it may be employed in strengths of from ½ to 1 per cent.

Off. Prep.—Liquor Procainæ Hydrochloridum, *N. F.*

PRUNUM. N. F.

PRUNE

"Prune is the partly dried, ripe fruit of *Prunus domestica* Linné (Fam. *Rosaceæ*). Prune should contain from 30 to 35 per cent. of its natural moisture when used for pharmaceutical purposes." *N. F.*

Prunes; Pruneau noir, *Fr. Cod.*; Pflaume, Zwetsche, *G.*

Prunus domestica L. (*P. communis* Huds.), the common *plum tree,* is a small tree with hairy twigs, large dull green ovate leaves, with coarsely serrate margins and pubescent lower surface, large white flowers and drupaceous fruits. The exact native home of the plum is unknown but is thought to be in the Caucasus or trans-Caucasus regions. It is now found in many varietal forms scattered throughout the world, some of which are extensively cultivated for their edible fruits which, when dried, are called *"prunes."* Chief among the varieties grown for their fruit are var. *insitia* Bailey which has forms known as *Damson* and *Bullace Plums;* the var. *Juliana* de Candolle, yielding the *Prune de Saint-Julien* of the French; the var. *Cereola* Linnæus, yielding the *Reine Claudes* or *Green Gages;* and the var. *maliformis* Linnæus or *Mirabelle Plum.*

The Damson Plum is a small leaved and small fruited form which often develops when plums are left to run wild. We are of the opinion that its characters are more nearly those of the primitive parent than those of any other form or variety extant.

The prunes in the American market come chiefly from California and southern France. Prunes from Bordeaux, France, were formerly considered the best, but with the recent advances and improved methods of dehydration carried on in California, this state now markets dehydrated prunes which excel alike in appearance and flavor all of the commercial varieties prepared by the ordinary methods of sun or oven drying.

Description and Physical Properties.—"Oblong, ellipsoidal, more or less compressed, from 3 to 4 cm. long; externally brownish black, shriveled; the sarcocarp sweet and acidulous; putamen hard, smooth or irregularly ridged; seed shaped like that of the almond but smaller, and of a bitter-almond taste.

"Preserve prune in air-tight containers in a cool place." *N. F.*

Prunes have a feeble odor, and a sweet mucilaginous taste, which is generally also somewhat acid.

They contain uncrystallizable sugar, malic and benzoic acids, and mucilaginous matter. The following is given as the average of nine analyses of dried prunes: Water 29.30 per cent., nitrogenous material 2.35 per cent., fat 0.53 per cent., free acid 2.72 per cent., sugar 44.35 per cent., other nitrogen-free material 17.89 per cent., woody fiber (not including the stone) 1.48 per cent., ash 1.38 per cent. (König, *Nahrungsmittel*, ii, 397, 1880.) In Hungary a kind of brandy (*Zwetschenbranntwein*), containing about 40 per cent. of alcohol, is obtained from them, which in some districts is largely consumed. Bonneberg, a German chemist, has extracted from prunes crystallizable sugar equal to that of the cane.

Uses.—Prunes are official in the N. F. because of their use in the confection of senna. There is a common belief that they possess laxative properties, but it is improbable that they have any virtues in this direction not common to other fruits. The popular superstition concerning their effects upon the intestines has probably arisen from the almost universal habit of associating them with senna. Their most valuable rôle in medicine is as a flavoring agent.

Off. Prep.—Confectio Sennæ, *N. F.*

PRUNUS VIRGINIANA. U. S. (Br.)

WILD CHERRY Prun. Virg. [Wild Black Cherry Bark]

"Wild Cherry is a stem bark of *Prunus serotina* Ehrhart (Fam. *Rosaceæ*), collected in autumn and carefully dried. Borke, if present,

UNIVERSITY OF ILLINOIS LIBRARY CHEMISTRY

should be removed." *U. S.* "Wild Cherry Bark is the bark of Prunus serotina, *Ehrh.*, collected in autumn." *Br.*

Pruni Virginianæ Cortex, *Br.*; Wild Cherry Bark; Virginian Prune Bark; Rum, Whisky, or Cabinet Cherry, Wild Black Cherry; Ecorce de Cerisier de Virginie, *Fr.*; Wildkirschenrinde, Amerikanischer Zierstrauch, *G.*

The genus *Prunus* now includes the plums, almonds, peaches, apricots, and cherries, and comprises about one hundred and twenty species. They are generally distributed in the temperate regions of the northern hemisphere. In the United States there are about forty indigenous species.

Linnæus, in his *Species Plantarum,* describes under the name of *P. virginiana* a tree, the statements concerning which are equally applicable to the *black cherry* and *choke cherry.* The specimen now in the Linnæan herbarium is that of the choke cherry. For this reason the binomial, *P. virginiana* L., has been restricted by many botanists to the choke cherry. But since Linnæus did not consider his herbarium specimens as types and as there is no certainty that he used the specimen now in the Linnæan herbarium as a basis for the description which is equally applicable to both cherries, we are left only the old synonymy upon which to interpret the species and that is entirely that of the *black cherry.* We are inclined to the opinion that Linnæus, in recognizing only one American species of this group, regarded the *choke cherry* and *wild cherry* as conspecific. DuRoi and Miller both adopted the name *P. virginiana* for the black cherry or wild black cherry while Ehrhart coined the name *P. serotina* for the black cherry.

The *choke cherry* is distinguished from the *wild black cherry* by the following characteristics: The choke cherry has deciduous calyx lobes; oblong-obovate pointed endocarp (or stone); leaves broadly oval to oblong-obovate, and usually abruptly acuminate; inner bark with a rather disagreeable odor. The *wild black cherry* has persistent calyx lobes; the endocarp (or stone) oblong-obovate, usually gradually acuminate; leaves oblong or lanceolate-oblong, usually gradually acuminate; the inner bark and leaves possess an aromatic odor. The British synonym, "Virginian Prune Bark," for the bark is misleading; Virginian Peach Bark or Virginian Almond Bark would have been no more of a misnomer. Michaux observed specimens of these trees on the banks of the Ohio, from eighty to one hundred feet high, with trunks from twelve to fifteen feet in circumference, but usually met with in the Atlantic States the tree is much smaller. The trunk is regularly shaped, and covered with a rough blackish bark, which detaches itself semi-circularly in thick narrow plates. The leaves are alternate, oval-oblong, or lanceolate-oblong, acuminate, unequally serrate, smooth on both sides, of a beautiful brilliant green; the petioles are furnished with one or more reddish conspicuous glands. The flowers are small, white, and occur in long erect or spreading racemes. They appear in May, and are followed by globular drupes, about the size of a pea, and when ripe of a shining blackish-purple color. For a paper on the structure of species of *Prunus,* by E. S. Bastin, see *Proc. A. Ph. A.*, 1895, 211.

This tree is distributed from Ontario south to Florida, and westward to Dakota, Nebraska, Kansas, Indian Territory, and Eastern Texas. It extends along the mountain ranges of Western Texas, Mexico, and Pacific regions of Central America, Colombia, and Peru. In the United States it was once common throughout the Appalachian region. In the neighborhood of Philadelphia it affects open situations, growing solitarily in the fields and along fences, and seldom aggregated in woods or groves. It is highly valued by the cabinet-makers for its wood, which is compact, fine-grained, susceptible of polish, and of a light red tint which deepens with age.

Moser points out that collectors frequently mistake *P. virginiana* L. or choke cherry for *P. serotina* Ehrh. or black cherry, which is the official source of wild cherry bark. He presents a description of the two trees and of the characteristic features of their barks. (*A. J. P.*, 1909, lxxxi, p. 579.) Farwell reports that the bark of *P. demissa* (Nutt.) Walpers, a tree from west of the Rocky Mountains, has been found in commerce. It is much darker and the lenticels are much more prominent. The preparations made from it resemble the official wild cherry bark in color, odor and taste. Occasionally barks find their way into commerce as Prunus Virginiana which yield no odor of hydrocyanic acid when moistened and are probably obtained from other than the official wild cherry. (See Bastin, *A. J. P.*, 1895, and Finnemore, *P. J.*, 72.)

Wild cherry bark is collected in autumn and should be carefully dried and stored in closed containers. The commercial supplies consist of "rossed" and "unrossed" bark. *Rossed* bark is bark deprived of its borke. (The term "borke" is a word of German origin and is used to indicate that layer of the bark formed in some trees, as the sycamore and wild cherry, which scales off in patches; it is composed of cork and parenchymatous cells.)

Virginia, Indiana, North Carolina and Michigan furnish much of the bark of commerce. The chief substitute and adulterant for this drug is the bark of the *Prunus Virginiana* L. (*P. nana* DuRoi) commonly known as *choke cherry* bark. This differs from the bark of the wild black cherry by exhibiting no stone cells in the pericycle, by having medullary rays from 1 to 4 cells in width and by having more rosette aggregates of calcium oxalate in its phloem than monoclinic prisms. Ground wild cherry bark has frequently been adulterated with wood of the same species.

Description and Physical Properties.—"*Unground Wild Cherry.*—Usually in transverse curved pieces up to 8 cm. in width and from 0.5 to 8 mm. in thickness; outer surface of rossed bark light brown or greenish-brown, smooth, except for numerous lenticel-scars; outer surface of unrossed bark reddish-brown, glossy, smooth, with light colored, transversely elongated lenticels or roughened and flaky with gray lichens; inner surface light brown, with delicate, reticulate striations and numerous minute fissures; fracture short, granular; odor distinct, resembling bitter almond when macerated in water; taste astringent, aromatic, and agreeably bitter.

"*Structure.*—Outer layer, of several or many rows of very small cork cells; parenchyma, tangentially elongated, bearing chloroplasts, starch or calcium oxalate crystals; stone cells associated with small groups of bast fibers in a nearly continuous ring; medullary rays 1 to 8 cells wide, wavy or curved, starch-bearing and frequently separated from the phloem on one side by large intercellular spaces; between the medullary rays numerous small groups of stone cells, sometimes branched or modified into short bast fibers, and associated with crystal fibers.

"*Powdered Wild Cherry.*—Light brown, fragments of yellow brown cork, few; stone cells numerous, frequently elongated, with short branches or a wavy and irregular outline and with thick, lamellated, porous, strongly-lignified walls; bast fibers few, not greatly elongated, frequently accompanied by crystal-bearing fibers; calcium oxalate prisms or rosette aggregates numerous, from 0.010 to 0.075 mm. in diameter; starch grains single and compound, nearly spherical, from 0.002 to 0.015 mm. in diameter.

"Preserve Wild Cherry in tightly-closed containers, protected from light." *U. S.*

"In curved pieces or irregular fragments not more than three millimetres thick. Frequently covered with a smooth, thin, reddish-brown, papery cork, or, if this has been removed, exhibiting a greenish-brown cortex; marked with transversely elongated lenticels. Fracture short, granular; fractured surface reddish-gray. Inner surface reddish-brown, striated or reticulately fissured. In the bark numerous groups of sclerenchymatous cells of characteristic shape, but no typical bast fibres; in the parenchymatous cells minute starch grains and prismatic crystals of calcium oxalate. Slight odor; taste astringent, aromatic and bitter, recalling that of bitter almonds." *Br.*

The bark is obtained indiscriminately from all parts of the tree, though that of the roots is thought to be most active. The revisers of the Pharmacopœia believe with J. S. Perot that the bark is stronger when collected in autumn than in the spring.

Constituents.—All parts of the wild cherry, including the leaves, fruit, and the bark of the stem and of the root, yield on infusion hydrocyanic acid. This substance does not exist as such in the plant itself but is due to the action of an enzyme—identical with the *emulsin* or *synaptase* found in mustard, bitter almonds, etc.—upon a cyanogenetic glucoside which was, at one time, believed to be amygdalin; it is probably l-mandelonitrile, which is isomeric with prulaurasin found in the cherry laurel (see under *Amygdala amara*).

Besides the cyanogenetic principle, wild cherry bark contains tannic acid—according to Peacock (*J. A. Ph. A.*, 1923, xii, 774) about 3 per cent.—and a fluorescent bitter principle which is probably glucosidal. (See also Power and Weimer, *West. Drug.*, 1887, p. 331). Lemburger (*A. J. P.*, 1872) states that the tannic acid is most abundant in the bark in October and November, but, on the other hand, Cooley (*A. J. P.*, August, 1897) found more in the spring than in the fall. Free benzoic acid, probably from oxidation of benzaldehyde, is also present.

The amount of hydrocyanic acid yielded by the bark ranges from 0.05 to 0.35 per cent. According to Stevens and Judy (*A. J. P.*, 1895, 482, p. 534), the hydrocyanic content is higher in the bark of the root than of the stem, the bark of young trees gives a greater yield than of old trees, and thick bark than thin bark.

Its peculiar flavor and its medicinal virtues are injured by boiling, in consequence partly of the volatilization of the principles upon which they depend, partly upon a chemical change effected by the heat.

R. Rother (*A. J. P.*, 1887, p. 286), in searching for the fluorescent principle of wild cherry bark, obtained a reddish crystalline substance, soluble in water, chloroform, ether, and alcohol, the solution of which fluoresced strongly on addition of ammonia. Rother says that it does not agree in crystalline form with mandelic acid, but may be a derivative of it. (For elaborate analysis of this bark and of the leaves, see Power and Moore, *Tr. Chem. Soc.*, 1909, p. 243 and 1910, p. 1100, respectively.)

Uses.—Wild cherry bark has the stomachic effects of the simple bitters but is comparatively infrequently employed for this purpose. On the theory that hydrocyanic acid is a cough sedative, wild cherry bark has been popularly employed in the treatment of *bronchitis* of various types, but is of doubtful service. Its most frequent use is as a flavoring agent especially for cough-syrups.

Dose, from thirty to sixty grains (2.0–3.9 Gm.).

PULSATILLA. N. F.

PULSATILLA Pulsatil. [Pasque Flower]

"Pulsatilla is the dried herb of *Pulsatilla vulgaris* (Linné) Miller, *Pulsatilla pratensis* (Linné) or *Pulsatilla patens* (Linné) Miller

(Fam. *Ranunculaceæ*). Pulsatilla contains not more than 5 per cent. of foreign organic matter." *N. F.*

Wind Flower; Pasque Flower; Passe Flower; Meadow Anemone; Herba Pulsatillæ; Herba Venti,s. Nolæ Culinari; Pulsatille, Coquelourde, Herbe du Vent, *Fr.;* Kuchenschelle, *G.*

The genus *Anemone* of Linnæus (Fam. *Ranunculaceæ*) includes perennial herbs of temperate regions with acrid poisonous juices and radical and cauline leaves, the cauline leaves forming an involucre remote from a solitary or umbellate inflorescence. The sepals are numerous to few and petaloid. The petals are absent and the fruits represent flattened and pointed or tailed achenes. This genus contains two sub-genera or sections, viz., *Anemone* and *Pulsatilla.* The plants of the *Anemone* section possess flowers with short styles and no staminodes, whereas those of the *Pulsatilla* section have long plumose styles, and staminodes are present. The species yielding the drug Pulsatilla belong to the section which Persoon named *Pulsatilla.* This section has been given the full rank of a genus by Britton and other followers of the American code. *Pulsatilla vulgaris* (*Anemone pulsatilla* L.) and *P. pratensis* (*A. pratensis* L.) are native to Europe and Asia. The American Pasque Flower is known to botanists under a variety of names as: *Pulsatilla patens* (L.) Miller, *P. hirsutissima* (Pursh.) Britt., *Anemone Nuttaliana* DC., etc. It is indigenous to the United States and Canada, west of the Mississippi. It possesses ternately divided leaves whose lateral segments are 2-parted, the middle one being stalked and 1-parted, a sessile deeply and narrowly cleft involucre, and a purplish-blue to whitish calyx of 5 to 7 sepals.

The plant should be gathered at the time of flowering in spring and used in the fresh condition for preparing the best tincture. Most of the drug on the markets is dried. The chief present commercial source is Czecho-Slovakia, the supplies imported into the United States coming in bags or bales from Hamburg, Germany.

Description and Physical Properties.—"*Unground Pulsatilla.*—Leaves and flowering scapes matted, silky-villous, basal leaves with petioles up to 30 cm. in length, the latter hollow, often purplish in color, the blades twice or thrice deeply three- or four-parted or pinnately cleft, the lobes linear and acute, the base of the petiole more hairy than above and frequently attached to the short rootstock; flowering scapes up to 30 cm. in length, solid in the lower portion and hollow in the upper part, with sessile, involucral leaves near the flower, occasionally with remains of the dull purple hairy sepals and the dense-wooly, plumose-tailed achenes. Nearly odorless; taste very acrid.

"*Powdered Pulsatilla.*—Numerous simple, thick-walled hairs up to 2.5 mm. in length and up to 0.020 mm. in thickness; tracheæ up to 0.035 mm. in width and spiral markings or with simple or bordered pores; fragments of epidermal tissue with stomata, the latter being broadly elliptical and up to 0.055 mm. in length in leaf tissue and up to 0.065 mm. in length in stem tissue; some epidermal cells with wavy vertical walls; calcium oxalate crystals and starch grains few or absent." *N. F.*

The official species of anemone as well as a number of related plants yield a volatile oil from which can be separated a crystallizable intensely acrid substance known as *anemone camphor.* This is an unstable compound which splits up into *anemonin* and *iso-anemonic acid.* Anemonin is practically tasteless, but when melted or volatilized with vapors of boiling water it becomes quite irritant. The formula $C_{10}H_8O_4$ assigned by Beckurts has been confirmed by Meyer, who believes it is related to cantharidin (*Jahresb. Pharm.,* 1896). When treated with nascent hydrogen in an acid solution, anemonin yields *hydroanemonin,* $C_{10}H_{12}O_4$, which crystallizes from boiling petroleum in large colorless laminæ which contain 1 molecule of H_2O, melt at 78° C., and distil without decomposition at from 210° to 212° C. under a pressure of 10 mm. Hydroanemonin is much more stable than anemonin.

As the acrid principle is volatile, much of it is lost in the process of drying. Indeed some authorities state that the dried herb is inert.

Uses.—Pulsatilla is a powerful local irritant and when taken in sufficient amount produces gastro-enteritis with vomiting and purging and often accompanied with evidence of irritation of the kidneys, such as albuminuria and even hematuria. Bronevski (*Med. Press.,* 1886) and Noel and Lambert (*A. J. P.,* 1897) have studied the physiological action of anemonin. They agree that the drug is a powerful depressant to the central nervous system, and Bronevski says also to the heart, but Noel and Lambert could find no pronounced action upon the circulation.

Pulsatilla was extensively used by that group of physicians known as eclectics, in a large variety of conditions. There is no satisfactory evidence, however, that it possesses any therapeutic virtues not ascribable to its local irritating effect. It was supposed to act especially on the generative organs both in men and women, and to be useful in *dysmenorrhea* and *ovarian irritation;* also *epididymitis* and *orchitis.*

The *dose* of the powdered drug may be stated as two to ten grains (0.12–0.6 Gm.).

Off. Prep.—Tinctura Pulsatillæ, *N. F.*

PULVERES

POWDERS

Poudres, *Fr.;* Pulvern, *G.;* Polveri, *It.;* Polvos, *Sp.*

The form of *powder* is convenient for the exhibition of substances which are not given in very large doses, are not very disagreeable to the taste, have no corrosive property, and do not deliquesce rapidly nor undergo any chemical decomposition, on exposure.

Powders may be divided into the *simple,* consisting of a single substance, and the *compound,* of two or more mixed together. The latter only are embraced under the present head. In the preparation of the compound powders, the ingredients should be pulverized separately and then mixed. Deliquescent substances, and those containing fixed oil in large proportion, should not enter into the composition of powders intended to be kept,—the former because they render the preparation damp and liable to spoil, the latter because they are apt to become rancid and impart an unpleasant odor and taste. When deliquescent substances are extemporaneously prescribed, the apothecary should enclose them before delivery in parchment paper or other impervious covering; the same remark is applicable to volatile powders, as ammonium carbonate and camphor. The lighter powders may in general be administered in water or other thin liquid; the heavier, such as those of metallic substances, require a more consistent vehicle, as syrup, molasses, honey, or one of the confections. Resinous powders, if given in water, require the intervention of mucilage or sugar.

Powders whose dose is not too large may usually be most conveniently exhibited enclosed in gelatin capsules (see under *Gelatina*). These will hold generally up to about 10 grains of organic or 15 grains of inorganic drugs. Another useful container for powders is the *cachet de pain* or *konseal,* also called the *wafer capsule.* These are made of flour and water, usually circular in outline with a concavity in the center. They may be had in various sizes; the largest will hold up to 20 grains of most substances. In filling them, one wafer is placed upon a board, and the requisite amount of medicine is put in it; then a second wafer, whose interior margin has been wetted, is laid upon the first and pressed down upon it. When taken, they should be dipped in water, placed immediately upon a teaspoon containing a little water, and swallowed with a gulp of fluid.

In mixing powders the ingredients should not be added all together at once, but the more potent ingredient, or that present in the smallest amount should be mixed with an equal bulk of the diluent and thoroughly triturated until the mixture is uniform, after which another portion of the diluent or one of the other ingredients, if any are present, and the procedure repeated until all of the ingredients have been added and the mixture is of perfect homogeneity.

PULVIS AMYGDALÆ COMPOSITUS. Br.

COMPOUND POWDER OF ALMONDS

Confectio Amygdalæ; Conserva Amygdalarum, Confection of Almond; Conserve d'Amandes, *Fr.;* Mandeloonserve, *G.*

"Sweet Almonds, 60 *grammes;* Refined Sugar, in powder, 30 *grammes;* Gum Acacia, in powder, 10 *grammes.* Blanch and dry the Almonds; reduce them to a coarse powder; mix the Gum Acacia and Sugar; add to the powdered Almonds; mix." *Br.*

This is the old *Almond Confection* in powder form. It is intended to afford a speedy method of preparing the almond mixture, which, when made immediately from the almonds, requires much time, and which cannot be kept ready made. But from its liability to be injured by keeping, it is not to be commended.

Off. Prep.—Mistura Amygdalæ, *Br.*

PULVIS ANTIMONIALIS. Br.

ANTIMONIAL POWDER [James's Powder]

Pulvis Antimonii Compositus, Pulvis Jacobi; Poudre antimoniale de James, *Fr.;* Jamessches Antimonpulver, *G.*

"Antimonious Oxide, 25 *grammes;* Calcium Phosphate, 50 *grammes.* Mix." *Br.*

The *Pulvis Antimonialis* of the N. F. (see Part III) is a little stronger in antimony.

The only essential difference between the official and the Dublin powder is that the ingredients of the former are taken already prepared and mixed in fixed proportion, while those of the latter result simultaneously from one operation. The official powder is, of course, much more easily prepared, and less liable to uncertainty from any error in the process.

Michael Donovan believes that none of the official formulas fairly represent *James's powder,* and gives an elaborate history of this celebrated proprietary medicine, and a method for its preparation, in *P. J.,* 1869.

Uses.—This preparation is stated to be alterative, diaphoretic, purgative, or emetic, according to the dose in which it is given. It was formerly prescribed in febrile diseases, with a view to its diaphoretic effect.

As this preparation depends for its action on the presence in the alimentary canal of an acid which may form a salt with the antimonial oxide, it cannot always be relied on for a definite effect, being sometimes mild, and sometimes more active than might be desirable.

Dose, as a diaphoretic, from three to eight grains (0.2–0.5 Gm.) every third or fourth hour, given in the form of pill. In larger doses it is purgative and emetic.

PULVIS BUTEÆ SEMINUM. Br.

POWDER OF BUTEA SEEDS

"Soak Butea Seeds in Distilled Water; carefully remove the integuments; dry and powder the kernels." *Br.*

Uses.—(See *Butea Semina.*)

Dose, ten to twenty grains (0.6–1.2 Gm.).

PULVIS CATECHU COMPOSITUS. Br.

COMPOUND POWDER OF CATECHU

Poudre de Cashcuttie composée, *Fr.;* Zusammengesetztes Katechupulver, *G.*

"Catechu, in powder, 40 *grammes;* Kino, in powder, 20 *grammes;* Krameria Root, in powder, 20 *grammes;* Cinnamon Bark, in powder, 10 *grammes;* Nutmeg, in powder, 10 *grammes.* Mix." *Br.*

The *dose* of this agreeable, and active, astringent is from fifteen to sixty grains (1–4 Gm.).

PULVIS CINNAMOMI COMPOSITUS. Br.

COMPOUND POWDER OF CINNAMON

Poudre des Epices, P. des Aromates, Poudre aromatique, *Fr.;* Aromatisches Pulver, Gewürzpulver, *G.*

"Cinnamon Bark, in powder, 25 *grammes;* Cardamom Seeds, in powder, 25 *grammes;* Ginger, in powder, 25 *grammes.* Mix." *Br.*

The cardamom seeds should always be deprived of their pericarps before being weighed, and the powder, when prepared, should be kept in well-stoppered bottles.

The *aromatic powder* of the N. F. (see *Pulvis Aromaticus,* Part III) closely follows the formula of the U. S. IX and differs from the British preparation in containing nutmeg.

Uses.—The aromatic powder is stimulant and carminative, and the preparation may be given in the dose of from ten to thirty grains (0.65–2.0 Gm.), in cases of *enfeebled digestion with flatulence;* but it is chiefly used as a corrigent and adjuvant of other medicines. A mixture of aromatic powders in the form of a cataplasm is much used as a mild rubefacient, especially in nausea and vomiting, being applied over the epigastrium. Such a mixture is commonly called *spice plaster* and is official in the N. F. (see Part III), under the title *Pulvis Aromaticus Rubefaciens.* It contains clove, cinnamon, ginger, and capsicum, and the mixed powder may be distributed in a thin flannel bag, quilted in position, and the whole wet with bathing whisky when applied and covered with oiled silk.

Dose, fifteen to forty-five grains (1–3 Gm.).

PULVIS CRETÆ AROMATICUS. Br.

AROMATIC POWDER OF CHALK

Confectio Aromatica, *Lond.;* Poudre de Craie aromatique, *Fr.;* Gewürztes Kreidepulver, *G.*

"Cinnamon Bark, in powder, 10 *grammes;* Nutmeg, in powder, 8 *grammes;* Cloves, in powder, 4 *grammes;* Cardamom Seeds, in powder, 3 *grammes;* Refined Sugar, in powder, 50 *grammes;* Prepared Chalk, 25 *grammes.* Mix." *Br.*

This is the former "Aromatic Powder" of the Br. Pharmacopœia, with the addition of chalk and elision of saffron. It is also official in the N. F. V (see Part III). It is a warm stimulant and astringent, as well as antacid, and is well calculated for *diarrhea* connected with acidity and without inflammation. In such a combination, however, the due proportion and even the choice of the ingredients vary so much with the symptoms that they might well be left to extemporaneous prescription.

Dose, from fifteen to sixty grains (1.0–3.9 Gm.), in mucilage or sweetened water, frequently repeated.

Off. Prep.—Pulvis Cretæ Aromaticus cum Opio, *Br.*

PULVIS CRETÆ AROMATICUS CUM OPIO. Br.

AROMATIC POWDER OF CHALK WITH OPIUM

Pulvis Cretæ et Opii Aromaticus, *N. F.;* Aromatic Powder of Chalk and Opium; Poudre de Craie Opaciée, *Fr.;* Kreidepulver mit Opium, *G.*

"Aromatic Powder of Chalk, 97.5 *grammes;* Opium, in powder, 2.5 grammes. Mix. This Powder contains 2.5 per cent. of Opium." *Br.*

The N. F. powder is identical with the Br. (see Part III).

The addition of the opium greatly increases the efficacy of the compound powder of chalk in *diarrhea,* and its equal diffusion through the powder presents this advantage, that it may be conveniently given in minute doses applicable to infantile cases. Forty grains of the powder contain a grain of opium.

Dose, for adults, from fifteen to forty-five grains (1–3 Gm.).

PULVIS CRETÆ COMPOSITUS. U. S.

COMPOUND CHALK POWDER Pulv. Cret. Co.

Poudre de Craie composée, *Fr.;* Kreidepulver mit Gummi, *G.*

"Prepared chalk, 30 Gm.; Acacia, in very fine powder, 20 Gm.; Sucrose, in fine powder, 50 Gm.; to make 100 Gm. Mix the powders intimately by trituration and pass the product through a No. 60 sieve." *U. S.*

This official powder was introduced into the U. S. P., 1890, for the purpose of having on hand, in a convenient form, the dry powders necessary to make chalk mixture. (See *Mistura Cretæ.*)

This powder will be found, however, a very convenient basis for administering chalk in powder, and it will be easy to direct the addition of morphine, kino, pepsin, bismuth subnitrate, or any other indicated drug.

Dose, one-half to two drachms (2.0–7.7 Gm.).

Off. Prep.—Mistura Cretæ, *U. S.*

PULVIS EFFERVESCENS COMPOSITUS.
U. S. (Br.)

COMPOUND EFFERVESCING POWDER Pulv. Eff. Co. [Seidlitz Powder]

"The mixture in a blue paper weighs not less than 9.5 Gm. and not more than 10.5 Gm., and contains not less than 23 per cent. and not more than 27 per cent. of sodium bicarbonate [$NaHCO_3$], and not less than 73 per cent. and not more than 78 per cent. of potassium and sodium tartrate [$KNaC_4H_4O_6.4H_2O$]. The white paper contains not less than 2 Gm. and not more than 2.4 Gm. of Tartaric acid [$H_2C_4H_4O_6$]." *U. S.*

Pulvis Sodæ Tartaratæ Effervescens, *Br.;* Effervescent Tartarated Soda Powder; Pulveres Effervescentes Aperientes, *U S.* 1870; Seidlitz Powders; Poudre Gazogène laxative, Poudre de Seidlitz, *Fr.;* Pulvis aërophorus laxans, *P. G.;* Pulvis aërophorus Seidlitzensis, Abführendes Brausepulver Seidlitzpulver, *G.;* Polvo gasifero laxante, *Sp.*

"Sodium bicarbonate, dried and in fine powder, 30 Gm.; potassium and sodium tartrate, dried and in fine powder, 90 Gm.; tartaric acid, dried and in fine powder, 26 Gm. Mix the sodium bicarbonate intimately with the potassium and sodium tartrate, divide the mixture into 12 equal parts, and wrap each part in a blue paper. Then divide the tartaric acid into 12 equal parts, and wrap each part in a white paper. Preserve in well-closed containers in a dry place." *U. S.*

"No. 1 Sodium Potassium Tartrate, in dry powder, 7.5 *grammes;* Sodium Bicarbonate, in dry powder, 2.5 *grammes.* Mix. No. 2 Tartaric Acid, in dry powder, 2.5 *grammes.* Put No. 1 in blue paper, and put No. 2 in white paper." *Br.*

Test for Identity.—"To 5 cc. of an aqueous solution of the mixture in a blue paper (1 in 20) add 5 cc. of acetic acid, and when effervescence has ceased, shake the solution vigorously: a white, crystalline precipitate, soluble in ammonia T.S., separates." *U. S.*

Assay for Sodium Bicarbonate.—"Mix thoroughly the contents of a blue paper, then dissolve 2 Gm. of it in 80 cc. of distilled water, add 20 cc. of half-normal sulphuric acid, boil the solution until the volume is reduced to about 50 cc., and titrate the excess of acid with half-normal sodium hydroxide, phenolphthalein T.S. being used as indicator. Each cc. of half-normal sulphuric acid corresponds to 0.04201 Gm. of sodium bicarbonate.

"**Assay for Potassium and Sodium Tartrate.**—Proceed as directed under the assay for alkali salts of organic acids, using 2 Gm. of the mixture taken from the blue paper used in the preceding assay. The difference between the number of cc. of half-normal sulphuric acid consumed in this assay and in the assay for sodium bicarbonate, multiplied by 0.07056, represents the potassium and sodium tartrate. The sum of the percentage of sodium bicarbonate and of the potassium and sodium tartrate is not less than 99 per cent.

"**Assay for Tartaric Acid.**—The contents of the white paper should meet the requirements of the tests and assay under *Acidum Tartaricum.*" *U. S.*

Though named from the saline springs of Seidlitz, in Bohemia, Seidlitz powders do not correspond in composition with those famous waters. Of each pair of powders, one, much the smaller of the two, contains about thirty-five grains (2.25 Gm.) of tartaric acid, the other about forty grains (2.59 Gm.) of sodium bicarbonate mixed with about two drachms (7.7 Gm.) of Rochelle salt. The acid powder is usually put into a white paper, the alkaline into a blue paper, which latter should not be colored by aniline; a number of them are enclosed in a paper or tin box. They should not be kept in a damp place, as the tartaric acid is liable to deliquesce and be absorbed into the substance of the paper, thus altering the due proportion of the ingredients. The whole of the contents of the white paper has been known to disappear in the course of two or three years. The Rochelle salt is the ingredient upon which the aperient property mainly depends. In their administration, each powder is dissolved separately, the smaller in a fluidounce or more of water, the larger in twice or three times the quantity, and the two solutions are mixed gradually. A reaction takes place between the tartaric acid and the sodium bicarbonate, by which sodium tartrate is produced, adding somewhat to the laxative property of the draught, and carbon dioxide escapes, causing a brisk effervescence. The acid is in slight excess, and thus causes an agreeable acidity in the solution.

Uses.—These powders are refrigerant and aperient, and generally very acceptable to the stomach in consequence of the carbon dioxide eliminated. They are especially adapted to *febrile cases* with a somewhat irritable stomach. One pair of them will generally operate slightly, but, if required, two may be given at once, or the dose may be repeated every three or four hours until the desired effect is produced. The flavor may sometimes be advantageously improved by adding syrup of orange, or lemon to one of the solutions before admixture, and most persons prefer to dissolve the salts in very cold water, the saline taste being thereby greatly diminished. A lowering of the temperature always takes place, due to the solution of the salts.

Dose, one set of two powders.

PULVIS GLYCYRRHIZÆ COMPOSITUS.
U. S., Br.

COMPOUND POWDER OF GLYCYRRHIZA Pulv. Glycyrrh. Co. [Compound Licorice Powder]

Poudre de Réglisse composée, Poudre pectorale, *Fr.;* Pulvis Liquiritiæ Compositus, *P. G.;* Brustpulver, Pulvis Pectoralis Kurellæ, *G;*

"Senna, in very fine powder, 180 Gm.; Glycyrrhiza, in very fine powder, 236 Gm.; Washed Sulphur, 80 Gm.; Oil of Fennel, 4 Gm.; Sucrose, in fine powder, 500 Gm.; to make 1000 Gm. Mix the oil of fennel thoroughly with about one-half of the sucrose, then add the remainder of the sucrose and the other ingredients, and mix thoroughly. Finally, pass the powder through a No. 80 sieve, pulverize the residue if any should be left on the sieve, add it to the sifted powder, and mix thoroughly. Keep it in well-closed containers." *U. S.*

"Senna Leaves, in powder, 16 *grammes;* Liquorice Root, in powder, 16 *grammes;* Fennel fruit, in powder, 8 *grammes;* Sublimed Sulphur, 8 *grammes;* Refined Sugar, in powder, 52 *grammes.* Mix." *Br.*

Description and Physical Properties.—"Greenish-yellow to greenish-brown, with a fennel-like odor. The elements of identification are the tissues of glycyrrhiza and senna.

"Place 0.1 Gm. of Compound Powder of Glycyrrhiza in a test tube, moisten it with 2 cc. of alcohol, add 10 cc. of water, boil the mixture, cool, and filter. The filtrate is of a pale yellowish-brown color, which changes immediately to a yellowish-red on the addition of a drop of potassium hydroxide T.S.

"Compound Powder of Glycyrrhiza should be free from an odor of hydrogen sulphide." *U. S.*

The modification of this formula introduced by the U. S. in 1890, of using the oil instead of the fruit of fennel, is of advantage because of the greater uniformity of the product.

It would not seem *a priori* probable that the small amount of sulphur represented in an ordinary dose of this powder could perceptibly modify the laxative effect of the senna. Nevertheless the mixture is one of our most efficient and agreeable laxatives for the relief of habitual *constipation;* usually acting without much griping. It is a favorite laxative in *hemorrhoids* because of the softness of the movements usually produced. It may be conveniently taken by stirring up in a couple of ounces of water.

Dose, thirty to sixty grains (2.0–3.9 Gm.).

PULVIS IPECACUANHÆ ET OPII.
U. S. (Br.)

POWDER OF IPECAC AND OPIUM Pulv. Ipecac. et Opii [Compound Powder of Ipecac, Dover's Powder, Opii et Ipecacuanhæ pulvis compositus P. I.]

Pulvis Ipecacuanhæ Compositus, *Br., U. S.* 1870; Compound Powder of Ipecacuanha; Pulvis Doveri; Poudre d'Ipécacuanha Opiacée, *Fr. Cod.;* Poudre de Dover, *Fr.;* Pulvis Ipecacuanhæ Opiatus, *P. G.;* Doversches Pulver, *G.;* Polvere di oppio e di ipecacuana, Polvere del Dower, *It.;* Polvo de ipecacuana opiado, Polvo de Dower, *Sp.*

"Ipecac, in very fine powder, 10 Gm.; Powdered Opium, 10 Gm.; Lactose, in coarse powder, 80 Gm.; to make 100 Gm. Triturate the ingredients together thoroughly until the mixture is reduced to a very fine, uniform powder." *U. S.* "Ipecacuanha Root, in powder, 10 *grammes;* Opium, in powder, 10 *grammes;* Potassium Sulphate, in powder, 80 *grammes.* Mix. This Powder contains 10 per cent. of Opium." *Br.*

Description and Physical Properties.—"Grayish-white or very light brown; exhibiting coarse, angular, frequently more or less cone-shaped colorless fragments from 0.03 to 0.40 mm. in length, very slowly soluble in water and chloral hydrate T.S. and strongly polarizing light with a strong display of color (*fragments of lactose*); other elements of identification are the tissues of ipecac and the capsules of opium poppy." *U. S.*

The substitution of powdered sugar of milk for potassium sulphate in crystals as formerly used cannot be said to have improved this well-known powder, except in making it more agreeable to the taste. The U. S. process should have directed the powder to be sifted, in order to secure a thorough blending of the ingredients; the sifting should on no account be omitted by the operator. The potassium sulphate or the crystalline sugar of milk serves to promote that minute division and consequent thorough intermixture of the opium and ipecacuanha upon which the peculiar virtues of the compound depend, the potassium sulphate being preferable on account of the greater hardness of its particles. They also serve to dilute the active ingredients, and thus allow of their division into minute doses adapted to the complaints of children. This composition, though called Dover's Powder, does not precisely correspond with that originally recommended by Dover, which was prepared as follows: Four ounces of potassium nitrate and the same quantity of potassium sulphate were mixed in a red hot crucible, and afterwards very finely powdered; one ounce of opium, sliced, was then added, and ground to powder with the saline mixture; lastly, an ounce of ipecac with an ounce of licorice root, in powder, were mixed with the other ingredients. This process was adopted in a former French Codex, and has been retained with little change in the present. For a method of valuing Dover's Powder, by A. B. Prescott, see *A. J. P.,* Dec., 1878.

Uses.—This combination is widely employed under the name of Dover's Powder as a diaphoretic and sedative. It is especially prized in the early stages of the milder infections, such as *colds* and *influenza,* in which an effort is to be made to abort the disease by sweating. Because of its combination of sudorific and analgesic action it is also frequently employed in *muscular rheumatism.* Ordinarily as a sudorific about five grains should be administered either stirred up in water or as a bolus and preferably in connection with hot drinks and other measures for encouraging sweating. The dose may be repeated in four to six hours, when it is desirable to maintain a continued sudorific action.

Dose, three to ten grains (0.2–0.65 Gm.).

Off. Prep.—Pilula Ipecacuanhæ cum Scilla, *Br.*

PULVIS JALAPÆ COMPOSITUS.
U. S., Br.

COMPOUND POWDER OF JALAP Pulv. Jalap. Co.

Pulvis Purgans, Pulvis Jalapæ Tartratus, Pulvis Catharticus; Poudre de Jalap composée, *Fr.;* Jalapenpulver mit Weinstein, *G.*

"Jalap, in very fine powder, 35 Gm.; Potassium Bitartrate, in fine powder, 65 Gm.; to make 100 Gm. Mix the powders intimately by trituration and pass the product through a No. 60 sieve." *U. S.*

"Jalap, in powder, 30 *grammes;* Acid Potassium Tartrate, in powder, 60 *grammes;* Ginger, in powder, 10 grammes. Mix." *Br.*

Properties.—"Very light brown; when examined under a microscope it exhibits numerous, sharp-angular, colorless fragments mostly somewhat rectangular and with straight edges varying from 0.03 to 0.3 mm. in length, slowly soluble in water or hydrated chloral T.S. and polarizing light with a strong display of colors (fragments of crystals of *potassium bitartrate*); numerous starch grains of jalap, readily distinguished without the use of iodine T.S., usually single, occasionally 2- to 3-compound, and varying from 0.003 to 0.035 mm. in diameter; occasional fragments of laticiferous vessels and parenchyma with yellowish-brown walls, or tracheæ with bordered pores, and rosette aggregates of calcium oxalate from 0.01 to 0.035 mm. in diameter, that occur in jalap." *U. S.*

The rubbing of the bitartrate with the jalap is thought to favor its more minute division. Aside from this physical effect, the potassium bitartrate is calculated to increase the hydragogue action of the jalap and the powder is consequently employed chiefly in the treatment of *dropsies.* The proportion of bitartrate, however, is too small to exert any decided cathartic effect; a drachm of the powder would represent less than forty grains of the cream of tartar.

Dose, thirty to sixty grains (2.0–4 Gm.).

PULVIS KALADANÆ COMPOSITUS. Br.

COMPOUND POWDER OF KALADANA

"Kaladana, in powder, 30 *grammes;* Acid Potassium Tartrate, in powder, 60 *grammes;* Ginger, in powder, 10 *grammes.* Mix." *Br.*

This powder is used as a cathartic.

Dose, from ten to sixty grains (0.65–3.9 Gm.).

PULVIS KINO COMPOSITUS. Br.

COMPOUND POWDER OF KINO

Pulvis Kino et Opii Compositus, Compound Powder of Kino and Opium; Pulvis Kino cum Opio, *Br.* 1864; Powder of Kino and Opium; Poudre de Kino Opiacée, *Fr.;* Kinopulver mit Opium, *G.*

"Kino, in powder, 75 *grammes;* Opium, in powder, 5 *grammes;* Cinnamon Bark, in powder, 20 *grammes.* Mix. This Powder contains 5 per cent. of Opium." *Br.*

This is an anodyne astringent powder, useful in some forms of *diarrhea,* but of which the composition would be better left to extemporaneous prescription, as the proportion of the ingredients should vary with the circumstances. Twenty grains contain one grain of opium.

Dose, from five to twenty grains (0.32–1.3 Gm.).

PULVIS OPII COMPOSITUS. Br.

COMPOUND POWDER OF OPIUM

Poudre d'Opium composée, *Fr.;* Zusammengesetztes Opiumpulver, *G.*

"Opium, in powder, 10 *grammes;* Black pepper of commerce, in powder, 15 *grammes;* Ginger, in powder, 30 *grammes;* Caraway Fruit, in powder, 42 *grammes;* Tragacanth, in powder, 3 *grammes.* Mix. This Powder contains 10 per cent. of Opium." *Br.*

This seems to have been introduced in order to have at hand all the dry ingredients of the Confection of Opium. (See *Confectio Opii.*) Ten grains (0.65 Gm.) of the powder contain one grain (0.065 Gm.) of opium.

Dose, from five to fifteen grains (0.3–1 Gm.).

PULVIS RHEI COMPOSITUS. U. S., Br.

COMPOUND POWDER OF RHUBARB Pulv. Rhei Co. [Gregory's Powder]

Magnesia and Rhubarb, Gregory's Powder; Poudre de Rhubarbe composée, *Fr.;* Pulvis Magnesiæ cum Rheo, *P. G.;* Kinderpulver, Pulvis Infantum, s. P. Antacidus, *G.*

"Rhubarb, in very fine powder, 25 Gm.; Magnesium Oxide, 65 Gm.; Ginger, in very fine powder, 10 Gm.; to make 100 Gm. Triturate the rhubarb and ginger together, gradually add the magnesium oxide, continuing the trituration until the ingredients are thoroughly mixed, and finally pass the product through a No. 60 sieve." *U. S.*

"Rhubarb Root, in powder, 22 *grammes;* Light Magnesia, 66 *grammes;* Ginger, in powder, 12 *grammes.* Mix." *Br.*

Description and Physical Properties.—"A pinkish-white, mobile powder, becoming darker on exposure to moisture; it exhibits fine particles of magnesium oxide, numerous starch grains and characteristic fragments of tissues of ginger and rhubarb.

"Preserve in well-closed containers." *U. S.*

This is a good laxative antacid, well adapted to *bowel complaints,* especially in children.

Dose, for an adult, from one-half to one drachm (2.0–3.9 Gm.); for a child two or three years old, from five to ten grains (0.32–0.65 Gm.).

PULVIS SCAMMONIÆ COMPOSITUS. Br.

COMPOUND POWDER OF SCAMMONY

"Scammony Resin, in powder, 50 *grammes;* Jalap, in powder, 35 *grammes;* Ginger, in powder, 15 *grammes.* Mix." *Br.*

This does not appear to us a very eligible preparation.

Dose, from ten to twenty grains (0.65–1.3 Gm.).

PULVIS TRAGACANTHÆ COMPOSITUS. Br.

COMPOUND POWDER OF TRAGACANTH

"Tragacanth, in powder, 15 *grammes;* Gum Acacia, in powder, 20 *grammes;* Starch, in powder, 20 *grammes;* Refined Sugar, in powder, 45 *grammes.* Mix." *Br.*

This is applicable to the general purposes of the demulcents, but is chiefly employed in Great Britain as a vehicle for heavy insoluble powders.

Dose, one-half to one drachm (2.0–3.9 Gm.).

PUMEX. N. F.

PUMICE

"A substance of volcanic origin, consisting chiefly of complex silicates of aluminum, potassium, and sodium." *N. F.*

Pumice Stone; Ponce, Pierre Ponce, *Fr.;* Bimstein, *G.;* Pomice, *It.*

Pumice is a porous volcanic rock. Its spongy structure is believed to be due to the effects of aqueous vapor on the lava while still in a fluid state. While it is found in many volcanic sections, the bulk of the commercial supply comes from the Lipari Islands off the coast of Italy. Pumice also occurs in large areas in the western part of the United States and over 10,000 tons annually are produced in Nebraska. Because of its porous structure it is so light that it usually will float in water for some time, but eventually becomes waterlogged and sinks.

It is brittle and hard and relatively easily pulverized. Because of its hardness it is much used in the arts as an abrasive, either in the original form for removing the outer surfaces of bodies or "rubbing down" any inequalities, or in a powdered condition as the basis of metal polish.

Pumice is really a porous form of *obsidian*, which occurs usually in glassy form, and obsidian has been converted into pumice by heat. Volcanic lavas of various types may assume the porous form corresponding to pumice, but it is only those rich in silica that yield pumice of economic value. The sp. gr. of powdered pumice is about 2.3. The composition of pumice averages about as follows: Silica 70 to 75 per cent., iron and alumina oxides 15 to 20 per cent., calcium, magnesium, potassium and sodium compounds, traces.

Pumice was admitted to the National Formulary for use in several preparations to assist in distributing the particles of extracts, tar and resins to facilitate solution. It is described as follows:

Description and Physical Properties.—"Pumice occurs as very light, hard, rough porous gray mases, or as a gritty, gray-colored powder. It is permanent in the air, odorless and tasteless. The dry masses usually float on water.

"Boil 10 Gm. of Pumice with 50 cc. of distilled water for one-half hour, adding distilled water from time to time to maintain approximately the original volume and then filter; the filtrate is neutral to litmus, and one-half of this filtrate, when evaporated and the residue dried to constant weight at 110° C., yields not more than 0.01 Gm. of residue (*soluble substances*). The remaining half of the filtrate, after slightly acidulating with hydrochloric acid, does not yield a blue color with potassium ferrocyanide T.S. (*iron*). Boil 1 Gm. of Pumic with 25 cc. of diluted hydrochloric acid for one-half hour, adding distilled water from time to time to maintain approximately the original volume, and then filter the liquid; the filtrate yields upon evaporating to dryness, igniting and quickly weighing, not more than 0.05 Gm. of residue." *N. F.*

Pumice is official solely for pharmaceutical purposes.

PYRETHRI RADIX. Br.

PYRETHRUM ROOT

"Pyrethrum Root is the dried root of Anacyclus Pyrethrum *DC*." *Br.*

Pyrethrum, *U. S. IX;* Pellitory; Radix Pyrethri Romani; Spanish Chamomile, Longwort, Pellitory; Pyrèthre, P. vrai, Salivaire, *Fr.;* Bertramwurzel, Römische Bertramwurzel, *G.;* Pelitre (Raiz de), *Sp.*

Anacyclus Pyrethrum is a perennial, composite herb with a long fusiform root which sends up numerous stems, usually trailing at the base, erect in the upper portion, eight or ten inches high, and terminated by one large flower head. The leaves are doubly pinnate, with narrow, nearly linear segments of a pale-green color. The florets of the disk are yellow; the rays white on their upper surface, and reddish or purple beneath and at their edges. The fruit is an obovate achene with a short pappus.

The plant is a native of Northern Africa and is cultivated widely as an ornamental herb in gardens. The root is the part used under the name of pellitory, or *pellitory of Spain.* It is collected in autumn from plants growing in Algeria, and exported either direct or through France to Great Britain and the United States.

The German Pharmacopœia formerly recognized the root of *Anacyclus officinalis* Hayne (*A. Pyrethrum* Schrader), a plant cultivated in Magdeburg. The roots are smaller and thinner, attaining a length of 25 cm. and a thickness of 5 cm. They are externally grayish-brown; the bark is not radiating and does not contain many stone cells, such as are present in the official pyrethrum. The taste resembles that of the official drug but is even more pungent.

Properties.—Pyrethrum is officially described as "usually from five to ten centimetres long, and from ten to fifteen millimetres thick; unbranched, nearly cylindrical, or frequently tapering towards both extremities; the crown often bearing a tuft of nearly colorless hairs. Outer surface brown and longitudinally wrinkled. Fracture short. In transverse section, numerous, narrow, yellowish wood-bundles alternating with wider, brownish-grey medullary rays; in the cortex and medullary rays scattered, yellowish-brown oleo-resin ducts; in the parenchymatous tissue inulin, but no starch. Characteristic odor; taste pungent, salivant." *Br.*

The U. S. IX described the powder as "light to dark brown; when examined under the microscope it exhibits numerous spherical or irregular masses of inulin, the nature of which is especially seen with polarized light, and lignified fragments of the woody tissues and stone cells associated with cork; inulin in spherical granules or irregular masses, from 0.01 to 0.1 mm. in diameter, which is not affected by the addition of iodine T.S.; tracheæ with simple pores and reticulate or scalariform thickenings, usually associated with wood parenchyma and with few or no wood fibers; stone cells in groups, the cells more or less tabular in outline, and with thick, yellowish porous walls; cork in yellowish-brown or dark brown fragments. Pyrethrum yields not more than 5 per cent. of ash." *U. S. IX.*

Buchheim (*A. E. P. P.*, 1876, v) discovered an alkaloid, *pyrethrine,* to which the activity of the drug may be attributed. Pyrethrine when treated with alcoholic potassium hydroxide, splits up like piperine, and yields *piperidine* and *pyrethric acid.* Schneegans (*Proc. A. Ph. A.*, 1897, 736) has obtained pyrethrine in long branched needles united in tufts, melting at 46° C., with an extremely burning taste. It is soluble in absolute alcohol, acetone, ether, strong acetic acid, chloroform, and carbon disulphide, yields a yellow solution, which soon changes to red. *Pellitorin* of Dunstan and Garnett is probably identical with pyrethrine.

The chief adulterant of *pellitory* has been the root of *Corrigiola littoralis* L. (Fam. *Illecebraceæ*). It may be readily distinguished from the true pellitory root by exhibiting warty protuberances on its crown, by its cross section which exhibits 3 or 4 pale concentric circles, each alternating with a narrower translucent horny ring and by its absence of pungency.

Uses.—Pellitory is a powerful irritant, used almost exclusively as a masticatory in certain forms of *headache, rheumatic* and *neuralgic affections* of the face, *toothache,* etc., or as a local stimulant, in relaxation of the uvula. It is very rarely employed to-day. Its action upon the general system has not been studied to any extent, but 50 minims of a tincture of it very nearly killed a child three and a half years old. The symptoms were those of gastro-enteritis, followed by convulsions. (*London Practitioner,* Aug., 1876.)

Off. Prep.—Tinctura Pyrethri, *Br.*

PYROGALLOL. U. S.

PYROGALLOL Pyrogall. [Pyrogallic Acid]

"Trihydroxybenzene [$C_6H_3(OH)_3$ 1 : 2 : 3]." *U. S.*

Acidum Pyrogallicum; Trihydroxybenzene; Pyrogallol, *Fr. Cod.;* Acide Pyrogallique, *Fr.;* Pyrogallolum, *P. G.;* Pyrogallussäure, *G.;* Pirogallol, *It.*

This substance, although often called pyrogallic acid, is a triatomic phenol, $C_6H_3(OH)_3$, and not an acid at all; hence the change in the official title to "Pyrogallol." Of the three triatomic phenols indicated by theory, this is the best known, *phloroglucin* and *oxyhydroquinone* being the other two. It may be prepared synthetically, but is usually obtained as one of the results of the decomposition of gallic acid by heat, and may be obtained by submitting extract of galls to sublimation, the reaction produced by the heat being:

$$C_7H_6O_5 = C_6H_6O_3 + CO_2$$

The vapors of pyrogallol rise, and condense on the upper surface of the paper diaphragm. The chief difficulty in the process is to properly regulate the heat, as at a high temperature this acid passes rapidly into *metagallic acid,* and thus the product is diminished. When previously dried gallic acid is heated to 210° C. pure pyrogallol sublimes, but by this dry process much of the product is lost because of the rapidity with which pyrogallol decomposes at high temperatures; the yield is only about 25 per cent. when theoretically it should be nearly 75 per cent. De Luynes and Espandieu have succeeded in preventing this loss by decomposing gallic acid in water under pressure, instead of by dry sublimation. Gallic acid is introduced into a bronze boiler with twice or three times its weight of water; the temperature is raised to a point ranging from 200° C. to 210° C., and maintained at that point for half an hour, when the liquid is allowed to cool. The boiler now contains a slightly colored solution of pyrogallol. This is heated with a little pure animal charcoal, filtered, evaporated sufficiently, and set aside to crystallize. The crystalline mass obtained is somewhat colored. To obtain it entirely white, nothing more is necessary than to distil it in a vacuum. The carbon dioxide escapes through the joinings of the apparatus, while the aqueous vapor is retained. Another equally satisfactory procedure is that of Thorpe, for details of which see *A. J. P.*, 1881, p. 53, 236.

Description and Physical Properties.—"Light, white, or nearly white, odorless leaflets or fine needles. It acquires a grayish tint on exposure to air and light. One Gm. of Pyrogallol is soluble in 1.7 cc. of water, in 1.3 cc. of alcohol, and in 1.6 cc. of ether, at 25° C. It is very soluble in boiling water and in boiling alcohol.

"Pyrogallol melts between 130° and 133° C. An aqueous solution of Pyrogallol on exposure to air acquires a brown color and an acid reaction due to oxidation by the air. Absorption of oxygen and change of color take place very rapidly after the solution is rendered alkaline with an alkali hydroxide. An aqueous solution of Pyrogallol (1 in 10) reduces solutions of the salts of silver, gold, and mercury even in the cold. When freshly prepared 1 cc. of an aqueous solution of Pyrogallol (1 in 20) is colored brownish-red by a few drops of ferric chloride T.S. Freshly prepared ferrous sulphate T.S. produces a blue color in an aqueous solution of Pyrogallol (1 in 20).

"Ash: not more than 0.1 per cent. A freshly prepared solution of Pyrogallol (1 in 20) in recently boiled, distilled water is colorless or at most slightly yellow, and is neutral or only slightly acid to litmus paper.

"Preserve in well-closed containers, protected from light." *U. S.*

According to Rosing, of Christiana, it is always partially converted, when sublimed, into metagallic acid, to which probably it owes its acid reaction as generally found in commerce; for when quite pure it has no influence on litmus paper. One of its characteristic properties is its strong affinity for oxygen, in consequence of which it instantly undergoes change by contact with chlorine, iodine, bromine, and the acids which readily yield oxygen. Through the same property it rapidly reduces some of the metallic oxides, and its use in photography as a developing agent is based on this effect exercised on the salts of silver. Though unalterable in the air when quite dry, it is rapidly changed in alkaline solution by the absorption of oxygen, so that it may be used for ascertaining the proportion of this gas in a mixture of gases. Pyrogallol forms salts with bases but its acidic characters are not pronounced and the salts are quite unstable. In acid or neutral solutions it oxidizes to form *purpurogallol*, $C_{20}H_{16}O_9$, which crystallizes from alcoholic solution in brown needles, melting point 156°, insoluble in water and soluble in alkalies to form unstable blue compounds. In alkaline solutions the oxidation products are more difficult of identification. A dark brown water-soluble compound is produced, having the composition $C_{20}H_{20}O_{16}$, and a dark red crystallizable substance, soluble in ether, containing $C_{20}H_{20}O_{11}$, and related to purpurogallol. By the action of phthalic anhydride upon pyrogallol is formed *gallein*, a dye color much used in calico printing. By the action of glacial acetic acid upon pyrogallol in the presence of zinc chloride is formed gallacetophenone, $CH_3—CO—C_6H_2(OH)_3$, which has been used in medicine as a substitute for pyrogallol.

Uses.—Pyrogallol is an active irritant and in concentrated solution even caustic. It is somewhat germicidal, though distinctly inferior to phenol in power; according to Cooper (*B. M. J.*, 1912, i, 1235), its phenol coefficient is 0.8. When taken internally it is actively poisonous, its toxic effect being due in part to its local irritant action upon the alimentary tract, but also partly from a phenol-like action upon the central nervous system and a destructive effect upon the blood corpuscles. It causes a solution of the hemoglobin from the latter and a change of hemoglobin into methemoglobin, which, if death does not occur too soon, is manifested by the appearance of icterus and methemoglobinuria.

The toxic symptoms produced by it are vomiting and purging with collapse, pale or cyanosed lips, the skin often presenting a peculiar greenish hue or sometimes jaundiced; the urine is albuminous and may be brown or black from the presence of hemoglobin or methemoglobin. Fatty degenerations and enlargement of the liver, similar to those produced by phosphorus, have been noted by Personne. (*C. R. A. S.*, Oct., 1869.)

Even its external use is not devoid of danger, two deaths having been reported from its topical application, and Kuseh (*W. K. W.*, 1909) reports abortion in pregnant women from a 10 per cent. ointment.

Pyrogallol is used in medicine solely as an application in various skin diseases, especially *psoriasis*. In this condition it owes its therapeutic action probably to its reducing powers, although its local stimulating effect and antibacterial properties may also play a part in its usefulness. It is occasionally used in *lupus* for its caustic action. For medical purposes it is generally applied in the form of an ointment varying in strengths of from two to ten per cent.

PYROXYLINUM. U. S., Br.

PYROXYLIN Pyroxylin. [Soluble Gun Cotton]

"Pyroxylin is a product obtained by the action of a mixture of nitric and sulphuric acids on cotton, and consists chiefly of cellulose tetranitrate [$C_{12}H_{16}O_6(NO_3)_4$]." *U. S.*

Pyroxylon, *U. S.* 1870; Colloxylin, Gun Cotton, Collodion Cotton; Gossypium Igniarium; Fulmicoton soluble, *Fr.*; Schiessbaumwolle, Kollodiumwolle, *G.*; Piroxilina, *Sp.*

The U. S. X gives no process for this; that of the Br. is as follows:

"Cotton, 10 *grammes;* Sulphuric Acid, 50 *millilitres;* Nitric Acid, 50 *millilitres;* Distilled Water, *a sufficient quantity.* Mix the acids in a porcelain mortar; immerse the Cotton in the mixture, and after it is thoroughly wetted by the Acids stir it for three minutes with a glass rod; transfer it to Distilled Water, wash until free from acid, drain, and dry the Pyroxylin in a warm room." *Br.*

The present process of the Br. is better than that formerly recommended employing potassium nitrate and sulphuric acid. The method of the U. S. 1890 differed from the above chiefly in using a larger proportion of acids, and in directing that the maceration of the cotton be continued until the product was soluble in a mixture of one volume of alcohol and three of ether. For details of this and other methods see *U. S. D.*, 19th ed., p. 1030.

Gun cotton was discovered by Schönbein, of Basel, in Switzerland. The name is applied to several closely related, yet distinct, products. They are not, as was at first supposed, nitro-derivatives in which the group NO_2 merely replaces hydrogen, atom for atom, but compounds in which the nitric acid residue NO_3 is present, replacing OH groups of the cellulose formula. Thus, taking the doubled formula $C_{12}H_{20}O_{10}$ for cellulose, there is produced by the action of nitric acid under different circumstances $C_{12}H_{14}O_4(NO_3)_6$, and following this, successively, $C_{12}H_{15}O_5(NO_3)_5$, $C_{12}H_{16}O_6(NO_3)_4$, $C_{12}H_{17}O_7(NO_3)_3$, and $C_{12}H_{18}O_8(NO_3)_2$. The first of these, the hexanitrate, is insoluble in alcohol and ether, and constitutes the true explosive gun cotton. The soluble gun cotton used in the preparation of *collodium* is a varying mixture of the four lower nitrates, but is chiefly made up of the tri- and tetra-nitrates. The hexanitrate, when very thoroughly washed free from acid, is insoluble in water, alcohol, ether, and all mixtures of alcohol with ether. It constitutes the true explosive gun cotton, which when compressed in cakes and fired by a fulminate explodes with great violence. Other compounds intermediate between some of these have been described by different chemists, but Abel, the chemist of the Woolwich Arsenal in England, has shown that they were imperfectly purified preparations.

Description and Physical Properties.—"A yellowish-white, matted mass of filaments, resembling raw cotton in appearance, but harsh to the touch. It is exceedingly inflammable, burning, when unconfined, very rapidly and with a luminous flame. When kept in well-closed bottles and exposed to light, it is decomposed with the evolution of nitrous vapors, leaving a carbonaceous residue.

"Pyroxylin is slowly but completely soluble in 25 parts of a mixture of 3 volumes of ether and 1 volume of alcohol. It is soluble in acetone and in glacial acetic acid and is precipitated from these solutions on the addition of water.

"Saturate 0.5 Gm. of Pyroxylin with alcohol in a dish placed in cold water and ignite the Pyroxylin at the top. When combustion is complete and the dish heated to redness, no more than 0.3 per cent. of ash remains. Stir 1 Gm. of Pyroxylin with 20 cc. of distilled water for ten minutes and filter: the filtrate does not acquire an acid reaction. Evaporate 10 cc. of the filtrate from the preceding test to dryness on a water bath: not more than 0.0015 Gm. of residue remains (*soluble substances*).

"Preserve in cartons, packed loosely, and protected from light and moisture." *U. S.*

"Resembles cotton-wool, but is somewhat harsher to the touch. Highly inflammable. Readily soluble in a mixture of equal volumes of *alcohol* (90 per cent.) and *ether* (distinction from gun-cotton)." *Br.*

When kept for long periods, gun cotton is liable to spontaneous decomposition. The change is shown by the bottle in which the gun cotton is kept becoming full of nitrous acid vapor, and the substance is so far altered that it is no longer explosive or soluble in ether. The official direction to keep pyroxylin "in cartons, protected from the light" is a valuable precaution against decomposition. When kindled, gun cotton flashes off like gunpowder, burning without residue. Yet, according to Bleekrode, when wet with ether, or similar fluid, and touched with a light, the liquid will burn out of it without firing it. (*J. P. C.*, 4e sér., xviii.) Its inflaming point is at 187.7° C.

Prepared in various forms after acting upon it with solvents like amyl acetate, etc., to convert it into a plastic mass, the higher nitrates constitute the well known "smokeless powders" now so largely used in warfare. Pyroxylin, or soluble gun cotton, is now extensively used as the basis of transparent varnishes for lacquering metal and wood. When mixed with camphor it forms the combination known as *celluloid* which is plastic under certain conditions of temperature and pressure. The solvent employed is usually a mixture of methyl alcohol or acetone with petroleum benzin, the miscibility of which is affected by the addition of small quantities of compound ethers like amyl acetate. In medicine it is used as a protective covering, especially in the form of collodion.

Off. Prep.—Collodium, *U. S., Br.*

QUASSIA. U. S. (Br.)

QUASSIA Quass. [Bitter Wood]

"Quassia is the wood of *Picrasma excelsa* (Swartz) Planchon, known in commerce as Jamaica Quassia, or of *Quassia amara* Linné, known in commerce as Surinam Quassia (Fam. *Simarubaceæ*)." *U. S.* "Quassia Wood is the wood of the trunk and branches of Picræna excelsa, *Lindl.*" *Br.*

Quassiæ Lignum, *Br.;* Jamaica Quassia, Quassia Wood; Bitter Wood; Bitter Ash; Quassia Amara, *Fr. Cod.;* Quassie Amère, Bois amer de Surinam, Bois de Quassie, *Fr.;* Lignum Quassiæ, *P. G.;* Quassiaholz, Fliegenholz, *G.;* Quassia, Quassia della Giammaica, *It.;* Cuasia (Leno de), *Sp.*

The genus *Picrasma* is represented by eight species, which are found in the warmer regions of the Old and New World. They all possess a bitter wood and bark.

Picrasma excelsa (Swartz) Planchon (*Picræna excelsa* Lindley), as its name implies, is a lofty tree, sometimes attaining the height of not less than one hundred feet, with a straight, smooth tapering trunk, which is often three feet in diameter near its base, and is covered with a smooth, gray bark. The leaves are pinnate, the leaflets being petiolate and oblong pointed and arranged in opposite pairs, with a single leaflet at the end. The flowers are small, of a yellowish-green color, and disposed in panicles. They are polygamous and pentandrous. The fruit is a small black drupe. This species inhabits Jamaica and the Caribbean Islands, where it is called *bitter ash.* Most of the commercial quassia is obtained from this tree.

Quassia amara L. (*Picræna amara*), or bitter quassia, is a small tree or shrub, with alternate, imparipinnate leaves, consisting of two pairs of opposite leaflets, with an odd one at the end. The leaflets are elliptical, pointed, sessile, smooth, of a deep green color on their upper surface, and paler on the under. The common petiole is articulated and winged. The flowers, which are hermaphrodite and decandrous, are bright red, and terminate the branches in long racemes. The fruit is a two-celled capsule containing globular seeds. *Quassia amara* is a native of Surinam, and is found in Brazil, Guiana, Colombia, Panama, and the West Indies, as also in some tropical countries of the Old World. Its root and bark were formerly official. They are excessively bitter, as in fact are all parts of the plant. For the botanical description and history of *Quassia amara,* see J. U. Lloyd, *West. Drug.,* 1897, 7; also Gilling (*P. J.,* 1908, lxiii, p. 30).

About 225,000 pounds of quassia were imported into the United States in 1924 from Kingston and St. Ann's Bay, Jamaica, and from

Hamburg and London. The drug imported from Jamaica comes in the form of logs which are used in the manufacture of "quassia" or "tonic cups." The waste shavings and chips are then sold to the drug trade. The drug from Hamburg is milled into "cut quassia" and occurs in irregular cubes.

Quassia is at first whitish, but becomes yellow by exposure, and sometimes has blackish spots or markings, due to the presence of the mycelium of a fungus. The two varieties are thus officially described:

Description and Physical Properties.—"*Unground Jamaica Quassia.*—Usually in chips, raspings or shavings, occasionally in billets; yellowish-white or bright yellow, with a few light gray pieces; somewhat coarsely grained; fracture tough, fibrous; odor slight; taste very bitter.

"*Structure.*—Tracheæ large, occasionally with yellowish contents, usually in groups of 2 to 6 and surrounded by numerous wood fibers; medullary rays lignified, mostly 1 to 5 cells wide and from 10 to 20 rows deep; lignified parenchyma cells in interrupted tangential bands and containing calcium oxalate or starch grains.

"*Unground Surinam Quassia.*—Resembles Jamaica Quassia except that the billets are usually thinner, the tracheæ single or in pairs and smaller, the medullary rays usually 1 to 2 cells wide and from 10 to 30 rows deep, and the calcium oxalate crystals few or entirely absent.

"*Powdered Quassia.*—Pale yellow; containing fragments of tracheæ, the walls marked by numerous small, bordered pores; wood fibers with thin walls and oblique pores; medullary-ray and parenchyma cells with numerous pores; calcium oxalate in 4- to 6-sided prisms, from 0.006 to 0.030 mm. in length, sometimes in crystal fibers; starch grains few, spherical or ellipsoidal, and from 0.005 to 0.015 mm. in diameter." *U. S.*

The Br. recognizes only the Jamaica quassia which it describes as follows: "In logs of varying length, or in chips or raspings; yellowish white, tough and dense, but easily split. In longitudinal section, elongated cells containing single crystals of calcium oxalate; in transverse section, medullary rays mostly two or three cells wide. No odor; taste intensely bitter." *Br.*

Constituents.—The chemistry of quassia seems to merit further study. It is apparently well established that the active principles of the Jamaica quassia and of the Surinam variety are different. According to Massute (*A. J. P.*, 1890, p. 338), the Jamaica quassia (*Picrasma excelsa*) contains two related compounds—*alpha-picrasmine* and *beta-picrasmine*, which are neither alkaloids nor glucosides. The first named was in needles, melted at 204° C., and had the composition $C_{35}H_{46}O_{10}$, while the other was in prisms, melted at 209° to 212° C., and had the composition $C_{36}H_{48}O_{10}$. Both of these are homologues of a third crystalline principle, $C_{29}H_{34}O_{10}$, melting point 212° to 216° C., which occurs with them.

Alpha-picrasmine when heated with hydrochloric acid is changed into an acid substance, *picrasmic acid*, which has the formula $C_{33}H_{42}O_{10}$.

In addition to these bitter principles, there is present also a small amount of a yellow crystalline substance which imparts a blue fluorescence to acidulated alcohol.

The Surinam quassia contains, apparently, a homologous series of four bitter substances. The term *quassin* (*quassiin*) is sometimes applied to the mixture of these bitter principles, but more properly should be limited to the more abundant of these principles. This occurs in the form of colorless crystals freely soluble in alcohol or chloroform, sparingly soluble in water or ether. Its solutions are intensely bitter, rotate polarized light to the right, reduce Fehling's solution and tend to become yellowish on exposure to the air. The crystals melt at 210° to 211° C. Oliveri and Denaro (*A. J. P.*, 1885, p. 29) assert that when heated with hydrochloric acid it is demethylated, forming *quassic acid*. They assign to this compound the formula $C_{32}H_{44}O_{10}$, but Massute gives the formula as $C_{32}H_{40}O_{10}$. Of the other principles, according to Massute, one melted at 239° C. to 242° C.; this was in too small quantity to be further studied. A third principle melted at 215° to 217° C. and the fourth at 221° to 226°. Besides these four principles there is present also a yellow fluorescent principle mentioned under picrasmine. Oliveri and Denaro believe that quassin is a derivative of anthracene. Dymock and Warden believe that they have obtained quassin from the wood of *Picrasma quassioides* (Ham.) Benn. of India.

Uses.—Quassia was introduced into medicine about the middle of the 18th century by a negro of Surinam, named Quassi, who acquired considerable reputation in the treatment of the malignant fevers of that country by a secret remedy, which he was induced to disclose to Rolander, a Swede, for a valuable consideration. Specimens were taken to Stockholm by this gentleman in the year 1756, and the medicine soon became popular in Europe. The name of the negro has been perpetuated in the generic title of the plant. But the quassia of Surinam is now comparatively little used, it having been superseded by the product of *Picrasma excelsa* from the West Indies.

Quassia is among the most powerful of the simple bitters, useful in *failure of appetite* due to gastric debility, and in overdoses capable of sufficiently irritating the stomach to produce vomiting. Its active principle, *quassin*, has been studied by Comparden, who asserts that in moderate doses it acts as a stimulant to the salivary, hepatic and renal secretions, and in overdoses causes burning pain in the esophagus, with headache, nausea, vertigo, vomiting, diarrhea, and muscular cramps. It is also stated that if given in doses of six-tenths of a grain (0.04 Gm.) before meals it increases markedly the alvine discharges, and that it is especially useful in *constipation* from debility of the muscular and intestinal coats. On the other hand, Krogmann (*A. E. P. P.*, 1922, xciv, p. 97) finds that Simaruba bark is a depressant to involuntary muscle and recommends it in excessive intestinal peristalsis due to inflammatory states. The dose of pure quassin is from one-tenth to three-tenths of a grain (0.006–0.02 Gm.).

An infusion of quassia, two ounces in a pint of water, affords a valuable and safe injection for *seat-worms.*

Syrupus Quassiæ.—This syrup is used in the preparation of a harmless fly-poison. Macerate, during twenty-four hours, 1000 parts of quassia wood with 5000 parts of water, then boil for half an hour, set aside for twenty-four hours, and press; mix the liquid with 150 parts of molasses, and evaporate to 200 parts. A weaker decoction of quassia does not kill the flies. From this the *Fly Water* or *Fly Plate* is prepared as follows: Mix when needed, and dispense without filtering, 200 parts of syrup of quassia, 50 parts of alcohol, and 750 parts of water. It is used by moistening with the mixture a cloth or filtering paper on a plate.

Quassia is given in infusion, tincture, extract, or fluidextract. Some *dyspeptic* patients who have become habituated to its bitterness, chew the wood occasionally with benefit.

Dose, five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Infusum Quassiæ, *Br.;* Tinctura Quassiæ, *Br.;* Fluidextractum Quassiæ, *N. F.*

QUERCUS. N. F.

QUERCUS Querc. [White Oak Bark]

"Quercus is the dried inner bark of the trunk and branches of *Quercus alba,* Linné (Fam. *Fagaceæ*). Quercus contains not more than 2 per cent. of its outer bark or wood or other foreign organic matter." *N. F.*

Oak; White Oak; Stone Oak; Ecorce de Chêne, *Fr.;* Cortex Quercus, *P. G.;* Eichenrinde, *G.;* Quercia, Corteccia de quercia, *It.*

There are more than fifty species of oak found in the U. S. Many of these are applied to important practical purposes. The official species known as the White Oak is a large handsome tree with leaves deeply pinnatifid-lobed. It is readily distinguished from other species by its light gray-colored, almost white bark which scales off in thin plates. The White Oak abounds from Maine to Ontario and southward to Florida and Texas. Its tough close-grained wood is the most highly valued of all the American oaks, except the live oak (*Q. virginiana* Mill.). The leaves are regular and obliquely divided into oblong, obtuse, entire lobes, which are often narrowed at their base. When full grown, they are smooth and light green on their upper surface, and glaucous beneath. Some of the dried leaves remain on the tree during the whole winter. The acorns are large oblong-ovoid or ellipsoidal, contained in rough, shallow, grayish cups, and supported singly or in pairs upon peduncles nearly 2.5 cm. in length.

The commercial supplies of oak bark used in the United States come largely from Michigan and Germany. The imported drug consists of cut and sifted bark and is shipped in bags. Other species of oak have been used in medicine, chiefly for their astringent properties. The *British oak* (*Quercus robur* L.) is widely distributed all over Europe and Northern Asia. There are two distinct varieties of it, one, *pedunculata,* with sessile or shortly stalked leaves and the acorns on long peduncles; the other, *sessiflora,* with the leafstalks more or less elongated and the acorns either sessile or provided with a very short peduncle. The dried bark of the smaller branches of the first variety (*Q. pedunculata* Willd.) were formerly recognized by the Br. Pharmacopœia (1885) under the name of *Quercus Cortex.*

The *Black Oak, Q. velutina* Lam. (*Q. tinctoria* Bartram), was official in the U. S. V. Like the white oak it contains much tannin, but is medicinally inferior because of its bitter taste and its staining properties. Its tinctorial powers are due to the presence of a peculiar coloring principle, *quercitrin.* The black oak has its trunk covered with a deeply furrowed bark, of a black or dark brown color. The leaves are ovate-oblong, pubescent, slightly sinuated with oblong, aculeate lobes. The fructification is biennial. The acorn is globose, flattened at top, and placed in a saucer-shaped cup. Moore (*Proc. Chem. Soc.,* 1910, xxvi, 183) assigned to quercitrin the formula $C_{21}H_{20}O_{11}.2H_2O$, and this is confirmed by Rudolph. (*Ph. Post,* 1893, 529.) The reaction for its decomposition is

$$C_{21}H_{20}O_{11} + H_2O = C_{15}H_{10}O_7 + C_6H_{12}O_5$$

the products being *quercetin* and rhamnose in equal molecules. Quercetin, also known as *meletin, quercitinic acid* and *flavin,* is a derivative of *flavone,* being a tetrahydroxyflavone. It is a brown crystalline powder, melting point 313° C. Soluble in alkaline solutions. Flavone is a phenyl derivative of *chromone.*

Quercitrin forms yellowish crystals, which, pulverized, yield a citron-yellow powder. It is neutral in reaction, is odorless, and in the dry condition tasteless, but in hot aqueous or alcoholic solution has a bitter taste. It fuses at 168° C. to a resinous mass. It is almost insoluble in cold water, sparingly soluble in hot water, and easily soluble in alcohol and alkaline or acid solution. Besides this principle, the bark contains much *quercitannic acid;* but it is less used in tanning than the other barks, in consequence of the color which it imparts to the leather. The bark of the black oak, deprived of its epidermis and reduced to a coarse powder, is largely used for dyeing woollen goods, under the name of *quercitron.*

Quercitrin has been found in various other plants, as in the leaves of *Ruta graveolens,* and the flower buds of *Capparis spinosa, Sophora japonica,* and *Æsculus Hippocastanum,* or horse chestnut. As this principle is capable of assuming various colors under various chemical influences, the idea has been advanced that it might be the coloring principle of flowers.

White oak bark, deprived of its epidermis, is of a light-brown color, of a coarse, fibrous texture, and not easily pulverized.

Description and Physical Properties.—"*Unground Quercus.*—In nearly flat pieces, from 2 to 10 mm. in thickness; externally light brown, becoming darker with age, rough-fibrous; fracture uneven, coarsely fibrous. Odor distinct; taste strongly astringent; not tingeing the saliva yellow when chewed.

"*Powdered Quercus.*—Light brown; fibers long, thick-walled, lignified from 0.015 to 0.033 mm. in width; numerous crystal fibers containing calcium oxalate in prisms from 0.010 to 0.050 mm. in diameter or in rosettes from 0.010 to 0.025 mm. in diameter; starch grains up to 0.010 mm. in diameter; stone cells with thick lamellated walls and simple pores up to 0.100 mm. in length; fragments composed of parenchyma with yellowish brown amorphous contents or of cork cells with a brownish amorphous content." *N. F.*

Constituents.—The medicinal value of oak bark depends on the presence of a peculiar tannin, known as *quercitannic acid,* of which it contains from 6 to 11 per cent. It belongs to the group of tannins that give brownish-green precipitates with ferric salts.

Lowe (*Zeit. An. Chem.,* xx, p. 208) says quercitannic acid occurs in two forms, one soluble in water and the other insoluble in that solvent. It is probable that all of the analyses of all of the earlier investigators were faulty because, as Trimble suggested, of the lack of authenticity of the extract used.

Etti (*M. Chem.,* x, 647) isolated from the wood of the Slavonian oak a tannin which proved to be a ketonic compound with the formula $C_{16}H_{14}O_9$. He was able to produce several anhydrides having the respective formulas $C_{32}H_{24}O_{16}$, $C_{32}H_{20}O_{14}$ and $C_{32}H_{18}O_{13}$. When boiled with dilute sulphuric acid a molecule of water is extracted from quercitannic acid with the formation of a coloring matter, *oak red.*

There is present also a small amount of a bitter principle, *quercin* $C_{15}H_{12}O_9$. The statement of Husemann that this is an impure quercite (a sugar found in acorns) seems improbable in view of the fact that quercite is sweet and quercin bitter. *Quercite* (*quercitol*), $C_6H_7(OH)_5$, is pentahydroxy-cyclohexane.

Acorns are highly nutritious containing besides starch, fat and protein, a peculiar unfermentable sugar known as *quercite.* Most of them are unfit for human food because of the presence of bitter principle, but some of the European species of oaks produce acorns free from bitterness, and it is stated that the American Indians employed even the native species, the bitter principle being removed by decoction.

Uses.—Oak bark is used in medicine solely as an astringent. It is not employed for internal use but affords a cheap astringent wash and is sometimes employed as an injection in *leucorrhea* or *hemorrhoids.*

Dose, fifteen grains (1 Gm.).

Off. Prep.—Fluidextractum Quercus, *N. F.*

QUILLAJÆ. N. F. (Br.)

QUILLAJA Quillaj. [Soap Tree Bark, Soap Bark]

"Quillaja is the dried inner bark of *Quillaja Saponaria* Molina (Fam. *Rosaceæ*). Quillaja contains not more than 5 per cent. of outer bark and not more than 1 per cent. of foreign organic matter." *N. F.*

"Quillaia Bark is dried inner part of the bark of Quillaja Saponaria *Molina.*" *Br.*

Quillæ Cortex, *Br.;* Quillaia Bark; Soaptree Bark; Soap Bark; Panama Bark; Bois de Panama; Ecorce de Quillaya, *Fr.* Cortex Quillayæ, *P. G.;* Seifenrinde, *G.*

The name of this genus is said to be derived from the popular name of the tree *Quillay,* which in turn comes from the Chilian word *quillean,* to wash.

Quillaja Saponaria Molina is a large polygamo-diœcious tree with alternate, short petiolate, ovate leaves with dentate margins, large white flowers and leathery follicular fruits occurring in clusters of 5. The bark is thick, the wood very hard. This tree was first described by the famous Abbé Giovanni Ignazio Molina in the *Saggio sulla Storia naturale del Chili,* published at Bologna, in 1782. The tree is a native of Chile, but is now cultivated in southern California and northern Hindostan.

Two spurious soap barks have appeared in commerce the botanical origins of which have not been definitely ascertained. One of these, thinner than the authentic article, with a reticulated outer surface, has been thought to be derived from *Quillaja Poeppigii* Walp. The second occurs in quills 7 to 15 cm. long, 1 to 2.5 cm. wide and about 3 mm. thick, is softer and not layered and is said to be derived from *Q. Smegmadermos* DC.

About 750,000 pounds of soap bark were imported into the United States during 1924. The chief bulk of the commercial supply comes from Valparaiso, Chile. The Chilean bark represents the crude inner bark and is shipped in burlap bags. Soap bark is also imported into the U. S. A. from Hamburg, Germany. This supply arrives here in two types. One type consists of square chips and is designated as "cut drug;" the other is designated as "siftings" and is usually high in ash (up to 20 per cent.). Some of the commercial supplies are utilized in the manufacture of metal polishes.

Description and Physical Properties.—"*Unground Quillaja.*—In flat pieces of variable length, from 3 to 8 mm. in thickness, or in small chips; outer surface brownish white, sometimes with a very few small patches of cork attached, otherwise nearly smooth; inner surface yellowish white, nearly smooth, with occasional circular depressions, conical projections or transverse channels; fracture uneven and strongly fibrous, the laminæ oblique to each other. Odor slight; taste acrid.

"*Powdered Quillaja.*—Pinkish white; very sternutatory; calcium oxalate in elongated prisms either isolated or in crystal fibers, the prisms from 0.035 to 0.200 mm. in length; numerous fragments composed of long, more or less irregular fibers with thick, strongly lignified walls, the fibers often associated with medullary rays the latter about 4 cells wide; stone cells with simple oblique pores; nearly spheroidal starch grains up to 0.010 mm. in diameter; occasional fragments composed of cork cells with brownish walls." *N. F.*

Soap bark is officially described in the Br. as "in flat pieces, from three to eight millimetres thick, but varying considerably in length and width. Outer surface brownish-white, or, where the outer bark has been incompletely removed, reddish or blackish-brown, and longitudinally striated. Inner surface white or yellowish-white and smooth. Fracture splintery and laminated, the tangential surfaces of the laminæ often exhibiting glistening prismatic crystals of calcium oxalate. In transverse section, chequered with delicate radial and tangential lines; medullary rays four cells wide; numerous irregular groups of bast fibres of varying size; scattered starch grains from four to six microns in diameter. Powdered Quillaja Bark is strongly sternutatory; *water* vigorously shaken with it forms copious persistent froth. Odor not marked; taste astringent and acrid. Ash not more than 15 per cent." *Br.*

The fracture exhibits, when slightly magnified, glistening prismatic crystals. Quillaja bark is histologically distinguished and its powder recognizable, by the large and numerous prismatic calcium oxalate crystals, which are from 0.035 to 0.200 mm. long.

When bruised and macerated in water quillaja bark imparts to that liquid the property of frothing like soap when agitated. The bark contains neither tannic acid nor any bitter principle. The detergent as well as medicinal properties of quillaja are due to the presence of at least two principles belonging to the group of saponins (see Part II). One of these is a neutral substance and seems to be identical with senegin (see *Senega*), the other known as *quillain* or *quillaic acid,* $C_{19}H_{30}O_{10}$, is an extraordinarily toxic substance. Both of these principles are glucosidal.

G. Melliers states that there is present in quillaja bark a carbohydrate which he has identified as *saccharose.* (*P. J.,* Feb., 1901, 161.)

Uses.—The effects of quillaja are those of the sapotoxins in general and are described under *Saponin* in Part II. Its use in medicine is based entirely on its local irritant action. Through its tendency to nauseate it is sometimes useful in the early stages of *acute bronchitis,* its action being very similar to that of senega, but it is comparatively little employed. Externally it is occasionally used for its detergent and stimulating effects. The quillaic acid is said to be extraordinarily poisonous, three-one-thousandths of a grain for each pound of body weight injected into the veins of a cat being sufficient to cause death, although thirty grains administered by the mouth are safely borne. Lohmann (*P. J.,* lxxiii, 477) affirms that chemically pure saponin is not injurious when taken by the stomach.

Both the active principles, quillaic acid and quillain, of quillaja bark are violent local irritants. In a case of poisoning by quillaic acid (*T. G.,* xi) the symptoms were violent vomiting, with epigastric pain, increased diuresis and cystic irritation, accompanied by cold sweats, feeble pulse, threatened syncope, and other evidences of collapse.

Quillaja is much used in the arts for washing silk, cloth, and other fabrics, for which soap would not be suitable. It is an emulsifying agent, but unless ordered by the physician should never be used by the pharmacist in the preparation of emulsions, on account of its active medicinal properties.

It has also been largely used in the production of foam on non-alcoholic carbonated beverages. This use has been criticized as harmful and it is now prohibited by law in many jurisdictions.

Off. Prep.—Liquor Picis Carbonis, *N. F., Br.;* Tinctura Quillajæ, *N. F.* (*Br.*).

QUINIDINA. N. F.

QUINIDINE Quinid.

"An alkaloid ($C_{22}H_{24}O_2N_2$ (324.31), isomeric with quinine, obtained from the bark of various species of *Cinchona* (Fam. *Rubiaceæ*)." *N. F.*

Conquinine; Beta-quinine; Chinotin; Pitayine; Chinidin, Conchinin, Beta-chinidin, *G.*

Quinidine is isomeric with quinine. It was discovered in 1833 by O. Henry and Delondre, but they afterwards concluded that it was quinine hydroxide, as it had the same composition as quinine. Winckler, in 1844, announced anew the existence of the same alkaloid, which he considered distinct, and named it "*chinidine*"; this substance was not pure, and Pasteur, in 1853, proved that it really consisted of two alkaloids, one of which he called *cinchonidine,* and the other *quinidine.* This view is now generally accepted, although Hesse insists on calling quinidine "*conchinine*"; but the latter name is used to only a limited extent in Germany, and scarcely at all elsewhere. It is found in several species of *Cinchona,* usually in small proportion, but in some, especially the *C. Calisaya* and *C. pitayensis,* in fairly large amount —as high as 3 per cent. has been reported.

It is prepared commercially from the "mother-liquors" from which quinine has been extracted. The solution left after the insoluble quinine sulphate has crystallized out is treated with ammonia which precipitates the cinchonine; after removal of the latter the addition of soda causes the separation of the quinidine. It may also be obtained from the mixture of alkaloids, called "quinoidine," that results from the addition of sodium hydroxide to the mother-liquor from which quinine sulphate has been removed. From this mixture the quinidine, together with cinchonine, is extracted with ether; this extract is dissolved in dilute sulphuric acid, then neutralized with ammonia, and the cinchonine precipitated with potassium tartrate.

Quinidine crystallizes with either one or two molecules of water, the crystals being strongly efflorescent. It is sublimable by heat without change, and is condensed in a crystalline form. It resembles quinine not only in composition, but also in its chemical relations with chlorine and ammonia, being rendered green by the successive action of those agents. According to Herapath, it resembles it also in causing a fluorescent appearance when dissolved in water, which is not the case with either cinchonine or cinchonidine, or at least, in a much less degree. It differs, however, in its greater facility of crystallization, in its much less solubility in ether, and in its influence on polarized light, it being dextro-rotatory. It may also be distinguished from quinine by the fact that its soluble salts are not precipitated by the neutral tartrates but are by potassium iodide; the latter test also differentiates it from all the other cinchona bases. The neutral sulphate is much more easily soluble than that of quinine. Vrevens (*C. D.*, 1898, p. 400) states that the crystals yielded by Marme's reagent (potassio-cadmium iodide) with quinidine are different from those obtained from any of the other cinchona alkaloids. They are seen under the microscope to consist of bundles of fine needle-like crystals quite different from those of quinine, cinchonine, and cinchonidine. Commercial quinidine is often contaminated with cinchonidine, indeed some samples may consist in chief part of the latter.

Description and Physical Properties.—"Quinidine occurs in acicular white crystals or as an amorphous white powder. When crystallized from alcohol it forms monoclinic prisms containing one molecule of alcohol which it slowly loses on exposure to air, and rapidly loses when heated to 100° C. When precipitated by ammonia water from an aqueous solution of a salt of Quinidine, washed and dried, it forms an amorphous powder. Odorless and having an intense and persistent bitter taste. When crystallized from an alcoholic solution, one gram dissolves at 25° C. in about 32 cc. of alcohol, 53 cc. of ether, and 1.5 cc. of chloroform; very slightly soluble in petroleum benzin; almost insoluble in water. One Gm. of dried amorphous Quinidine dissolves in about 36 cc. of alcohol at 25° C., 67 cc. of ether and 1.7 cc. of chloroform; very slightly soluble in petroleum benzin; almost insoluble in water.

"Quinidine melts at about 168° C. Incinerate 0.2 Gm. of Quinidine; no weighable residue remains. Its alcoholic solution is dextrorotatory, and its aqueous solution is alkaline to litmus. A solution of Quinidine in diluted sulphuric acid (1 in 1000) shows a strong blue fluorescence. Add a few drops of bromine T.S. to 10 cc. of an aqueous solution of Quinidine (1 to 1000), made with the aid of sufficient diluted sulphuric acid to produce complete solution, and then follow with ammonia water in slight excess; the liquid acquires an emerald-green color. A solution of about 0.1 Gm. of Quinidine in 5 cc. of sulphuric acid is not darker than pale yellow. Dissolve 0.5 Gm. of Quinidine in 10 cc. of distilled water at 80° C., with just enough sulphuric acid to form a solution neutral to litmus paper, and add a neutral solution of 0.5 Gm. of potassium iodide in 5 cc. of distilled water at 80° C. Agitate the mixture slightly, cool it to 15° C. and keep it at this temperature for one hour with occasional stirring. A white precipitate is formed (difference from *quinine*). Filter out the precipitate and add 2 drops of ammonia water to the filtrate; it does not cause more than a slight turbidity (*other cinchona bases*). Care must be taken to have the liquid perfectly neutral after the addition of the potassium iodide solution; if slightly acid, very dilute ammonia water must be added drop by drop, with constant stirring until exactly neutral to litmus paper.

"Preserve it in well-closed containers, protected from light." *N. F.*

The sulphate of this alkaloid is recognized by the U. S. P. and several other salts as the hydrochloride and tannate are commercially obtainable.

For description of the uses of this alkaloid see under *Quinidinæ Sulphas.*

Dose, two to five grains (0.12–0.30 Gm.).

Off. Prep.—Syrupus quinidinæ, *N. F.*

QUINIDINÆ SULPHAS. U. S.

QUINIDINE SULPHATE Quinidin. Sulph.

"The sulphate $[(C_{20}H_{24}O_2N_2)_2.H_2SO_4.2H_2O]$ of an alkaloid obtained from cinchona." *U. S.*

Chinidin Sulphate, Conquinine Sulphate; Sulphate de Quinidine, *Fr.;* Chinidin Sulfas; Schwefelsaures Chinidin, *G.*

For account of the sources and chemical properties of this base see preceding article.

Description and Physical Properties.—"Fine, needle-like, white crystals, frequently cohering in masses. It is odorless, has a very bitter taste, and darkens on exposure to light. One Gm. of Quinidine Sulphate is soluble in about 90 cc. of water, and in 10 cc. of alcohol, at 25° C. One Gm. is soluble in about 15 cc. of boiling water. It is soluble in chloroform but almost insoluble in ether.

"An aqueous solution of Quinidine Sulphate (1 in 100) is neutral or slightly alkaline to litmus paper, and is dextrorotatory. (Quinine sulphate is lævorotatory.) An aqueous solution of Quinidine Sulphate, when acidulated with diluted sulphuric acid, develops a vivid blue fluorescence. Add 1 or 2 drops of bromine T.S. to 5 cc. of an aqueous solution of the salt (1 in 1000) and follow with 1 cc. of ammonia T.S.: the liquid acquires an emerald-green color due to the formation of thalleioquin. To 5 cc. of an aqueous solution of Quinidine Sulphate (1 in 100) add 1 cc. of silver nitrate T.S. and stir the mixture with a glass rod: a white precipitate forms after a short interval (*difference from many other alkaloids*). Barium chloride produces in an aqueous solution of the salt a white precipitate which is insoluble in hydrochloric acid.

"Dried to constant weight at 100° C., Quinidine Sulphate loses not more than 5 per cent. (*water*). Ash: not more than 0.1 per cent. A solution of 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*). One Gm. of Quinidine Sulphate dissolves in 5 cc. of a warm mixture of 2 volumes of chloroform and 1 volume of dehydrated alcohol with not more than a slight turbidity (*ammonium or other inorganic salts*). Dissolve 0.5 Gm. of Quinidine Sulphate in 15 cc. of boiling water and add a solution of 0.5 Gm. of potassium iodide in 5 cc. of distilled water, which, if necessary, has previously been neutralized to litmus paper with tenth-normal sulphuric acid. A white precipitate is formed. Mix well, cool the mixture to 15° C., and keep it at this temperature for one hour with frequent agitation. Filter and add 2 drops of ammonia T.S. to the filtrate. No turbidity is produced within one minute (*other cinchona alkaloids*).

"Preserve in well-closed containers protected from light." *U. S.*

Uses.—Although quinidine possesses the antiperiodic and other properties of quinine and has been used as a substitute, it is so inferior that its employment for this purpose has almost completely ceased. In 1914 Wenkelbach reported remarkable effects in a patient suffering with auricular fibrillation, who had received quinidine for a malarial condition. This led Frey in 1918 to make some experiments with the use of quinidine in the treatment of this serious cardiac irregularity. Since then it has been used to a large extent not only in auricular fibrillation but in various other irregularities of the heart, especially paroxysmal tachycardia. Smith (*J. A. M. A.*, 1922, lxxviii, p. 877) collected the reports of 320 cases of auricular fibrillation treated with quinidine. It has been established beyond question that in a considerable proportion—between 50 and 60 per cent.—of these cases, normal heart rhythm is at least temporarily re-established. Where the disturbance of rhythm has been, as it usually is, dependent upon a valvular lesion, as the quinidine does not influence the latter the patient will probably sooner or later relapse; that is, the auricular fibrillation in the great majority of cases recurs sometimes after a few days and others after some weeks. In some cases, however, the normal rhythm has continued so long as to give promise of being practically permanent. The questions whether the patient is likely to be benefited by the re-establishment of normal heart rhythm and whether this likelihood is sufficient to outweigh the positive dangers of the drug is one which can be answered only by most careful study of all the surrounding conditions in each individual case.

The *modus operandi* of quinidine in these cases has been recently elucidated. Santessin (*A. E. P. P.*, 1893, xxxii, p. 327) showed that quinidine depresses the rhythmicity, contractility and irritability of the heart. Lewis (*Heart*, 1921, ix, p. 55) has shown that it also lowers conduction in the cardiac muscle, and Hofmann (*Z. B.*, 1920, lxxi, p. 47) that it lowers the excitability of the dog's heart to the electrical current (see also Hirschfelder and Cervenka, *J. P. Ex. T.*, 1925, xxvi, 19). The most plausible explanation of its effect is that it is due to a combined lessening of the irritability of the auricular muscle with a prolongation of its refractory period. It is of interest to note, in this latter connection, that Brody (*J. A. M. A.*, 1922, lxxix, p. 354) has shown a similar prolongation of the refractory period of the voluntary muscles after quinidine.

In considering the dangers from this drug, it should be noted in the first place that quinidine is to be regarded as a heart depressant, and if it fails to restore the normal rhythm of the heart, the patient's condition may be made perceptibly worse. The more serious dangers, however, are due to the dislodgment of an embolus from the heart, which may prove rapidly fatal if lodged in the brain or other vital organ, and the not infrequent idiosyncrasies towards the drug. The latter may be guarded against by the so-called test dose which is now practically always given. That is—the patient receives three grains (0.2 Gm.) of quinidine sulphate, and if no symptoms are produced, another three grains after two hours. Twenty-four hours later, if no unpleasant symptoms have occurred, is begun the therapeutic doses of the drug, which are usually from three to six grains, at such intervals that the patient receives from fifteen to thirty grains (1 to 2 Gm.) in the twenty-four hours. This is continued for about a week, unless the desired therapeutic effect occurs sooner or some toxic symptoms intervene. Against the dangers of embolism there is no way to guard, except to remember that they are much more likely to occur in cases of long standing than those in which the fibrillation is comparatively recent. There have been several sudden deaths following the use of the drug, some of which are not easily explained. In many other patients unpleasant symptoms such as headache, increased palpitation, precordial pain, nausea or vomiting, ringing in the ears, etc., have interrupted the treatment. It is generally recommended that no digitalis shall be administered during the quinidine treatment.

Dose, three to six grains (0.2–0.4 Gm.).

QUININA. U. S.

QUININE Quin.

"An alkaloid [$C_{20}H_{24}O_2N_2.3H_2O$] obtained from cinchona." *U. S.*

Chininum; Quinia; Quinine, *Fr.;* Chinin, *G.;* Chinina, *It.;* Quinina, *Sp.*

This alkaloid is prepared by adding to a solution of quinine sulphate a quantity of ammonia water or solution of sodium hydroxide just a sufficient quantity to cause a precipitation of the alkaloid.

Quinine is whitish, rather flocculent, and usually not crystalline; it may with care be crystallized from its alcoholic solution in silky needles, and Liebig obtained it from a somewhat ammoniacal aqueous solution in the same form. It is inodorous and very bitter. The crystals obtained from alcoholic solution have the composition $C_{20}H_{24}O_2N_2 + 3H_2O$, and fuse at 57° C. They may be deprived of water by warming or exposure over sulphuric acid, and they then fuse at 171.2° to 172° C. By carefully regulated heat, it may be sublimed unchanged, assuming a crystalline form. The alcoholic solution is intensely bitter. Quinine is unalterable in the air. It forms salts with the acids which readily crystallize. *Herapathite* was the name given by Professor Hardinger after the discovery in 1852, by Dr. W. B. Herapath, of a *periodide of quinine,* which has been used as an identifying test for this alkaloid. If an alcoholic solution of iodine is added to a solution of a quinine salt, a crystalline precipitate is formed which is golden-green by reflected light and pale olive-green by transmitted light. These crystals have been called *artificial tourmalines,* from their resemblance to that mineral.

Quinine and its salts may be distinguished from all other alkaloids and their salts, except a few others from cinchona, by the beautiful emerald-green color (*thalleioquin*) which results when their solution is treated first with solution of chlorine and then with ammonia, and which changes to a white or violet upon saturation with a dilute acid. (For further details of this test, seen under *Quininæ Sulphas.*)

Quinine, and to a less extent other cinchona alkaloids impart a fluorescence to their aqueous solution. This is more closely described under *Quininæ Sulphas.*

Description and Physical Properties.—"A white, microcrystalline, odorless powder. It has a bitter taste, which is intense and persistent. It is efflorescent in dry air. One Gm. of Quinine is soluble in 1560 cc. of water, 0.8 cc. of alcohol, 1.1 cc. of chloroform, 1.9 cc. of ether, and in 1890 cc. of ammonia water, at 25° C. One Gm. is soluble in 800 cc. of boiling water.

"An alcoholic solution of Quinine (1 in 10) is alkaline to litmus paper, and is lævorotatory. A solution of Quinine in diluted sulphuric acid shows a vivid blue fluorescence. Add 2 or 3 drops of bromine T.S. to 5 cc. of a saturated, aqueous solution of Quinine and add 1 cc. of ammonia T.S.: the liquid acquires an emerald-green color, due to the formation of thalleioquin.

"Dried to constant weight at 100° C., Quinine loses not more than 15 per cent (*water*). Ash: not more than 0.1 per cent. A solution of 0.1 Gm. of Quinine in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*). Heat 0.2 Gm. of Quinine with 2 cc. of sodium hydroxide T.S. on a water bath: the odor of ammonia is not evolved (*ammonia salts*). Dry Quinine to constant weight at 100° C., dissolve 1.5 Gm. of the dried Quinine in 25 cc. of alcohol, dilute the solution with 50 cc. of hot water, add normal sulphuric acid (about 5 cc.) until the solution is acid, using 2 drops of methyl red T.S. as indicator, and neutralize the excess of acid with normal sodium hydroxide. Evaporate the liquid to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for *other cinchona alkaloids* as directed under *Quininæ Sulphas.*" *U. S.*

The chemical structure of quinine has been the subject of much recent study by chemists and the problem appears to have been practically solved although the alkaloid has not yet been made synthetically. In the first place it may be noted that quinine is, structurally, a methoxy-cinchonine. When oxidized by chromic acid quinine is broken up into *quininic acid* and a substance called *meroquinenine.* The former of these is the methoxy derivative of quinoline-4-carboxylic acid. Meroquinene, on further oxidation, yields *loiponic acid* which is an ethyl-methyl-pyridine. The structural formula of Rabe (*B. Chem. G.,* 1918, li, 466) is accepted by most chemists. For account of the investigation into the quinine molecule and attempts at its synthesis, with references to literature, see Henry, *Plant Alkaloids,* 1924, p. 148.

The most important salt of quinine is the *sulphate,* the process for procuring which, as well as its properties, will be hereafter described. Besides the salts which are official, a number of other compounds have been employed in medicine; the important ones are described in Part II.

Incompatibilities.—The soluble salts of quinine are precipitated from their aqueous solution by the ordinary alkaloidal reagents, such as tannic acid, the alkaline carbonates and hydroxides, the iodides, etc. In addition they are precipitated by certain organic acids, especially the benzoates, salicylates and tartrates. There is a widespread belief that a poisonous substance—quinotoxin—is formed by the interaction between quinine and acetyl salicylic acid, but Sollmann asserts that the compound form in this reaction is really quinicin and is of low toxicity although not possessed of the therapeutic properties of quinine. (See *Quinotoxin*, Part II.)

Uses.—In sufficient concentration quinine appears to be poisonous to all forms of protoplasm, as well of the unicellular micro-organisms as of the more highly organized tissue of man. While the general antiseptic value of quinine is comparatively low against certain bacteria it is peculiarly efficient. McDonald (*J. A. M. A.*, 1915, lxiv, p. 505) has shown that the sulphate inhibits the growth of typhoid bacillus in the strength of 1 to 30,000, and Schaeffer, that 1 to 10,000 will inhibit the growth of diphtheria bacillus. (*Bio. Chem. Zeit.*, 1917, lxxxiii, p. 269.) Among the unicellular organisms, in general the protozoa are more susceptible than the bacteria, but the drug is peculiarly poisonous to the plasmodia of malaria.

In the frog moderate doses of quinine cause a diminution in the reflex activity which is generally attributed to a stimulation of the spinal inhibitory center, commonly known as Setschenow's center. Larger quantities are directly depressant to the motor ganglia. In mammals it frequently gives rise to convulsions, which appear to be due to irritation of the motor area of the brain. Locally applied it is paralyzing to both the motor and sensory nerves, but especially to the latter. In moderate dose it has no demonstrable influence upon the circulation, but large quantities—equivalent to 75 or 80 grains for man—are depressant to the heart. It increases the vigor of the contractions of the voluntary muscles, but apparently lessens resistance to fatigue. According to Cushny, it is a direct stimulant to the uterine muscle, increasing the force of the contractions but not greatly affecting the tonus.

As was shown many years ago by Binz, when added to the blood outside the body in the proportions of about 1 part in 4000, it caused an immediate cessation of the ameboid movements of the white corpuscles. This effect is probably simply one of the manifestations of its general protoplasmic toxicity, and plays little part in its therapeutic action. According to Roth (*J. P. Ex. T.*, 1912, iii, p. 470), quinine causes a pronounced leukocytosis; at first there is an increase in the number of lymphocytes which he believes is due to contraction of the spleen and lymphatic tissues, but later there is an increase in the number of polymorphonuclear cells. According to De Sandro (*Rif. M.*, 1910), the continued use leads to an increase in the number of both red and white cells in the blood.

It has for many years been almost universally taught by pharmacologists that quinine has a marked power of lessening heat production in the body by retarding nitrogenous metabolism. This view has, however, been strongly combated by Hardikar (*J. P. Ex. T.*, 1925, xxv, 175) who maintains that it is founded on erroneous observations. Although he found that very large doses produce a definite fall in heat formation in the rabbit he failed to obtain such an effect in human beings with doses up to 2 Gm., and does not believe it is possible to influence katabolism through the oral administration of quinine. Senta (*A. I. P. T.*, xviii, p. 217) has found a diminution in the absorption of oxygen and gaseous exchange of isolated bits of muscles. Although in normal man ordinary doses do not cause a reduction of temperature, yet they prevent the natural rise of temperature which takes place after violent exercise and in febrile patients often gives rise to distinct lowering. The question of the influence of quinine on metabolism should, in our opinion, be regarded as still *sub judice*.

Quinine is used in medicine for a large variety of purposes. The oldest and most important of these is for the treatment of *malarial fevers*, for which disease it is by far the most reliable remedy that we possess. While the curative value of the drug is universally acknowledged there is some difference of opinion as to its usefulness as a prophylactic against this disease. On the one hand, Stitt (*J. A. M. A.*, 1908, li, p. 1682) concludes that it has no prophylactic action against malaria and Treadgold (*B. M. J.*, 1918, i, p. 525) that it is even harmful. On the other hand, Rodgers (*Indian Med. Gaz.*, 1918, liii, p. 249) says that failure with quinine as a prophylactic is due to the use of too small doses at too long intervals; he recommends ten grain doses given at intervals of not more than four days.

Quinine is useful for its antipyretic influence in certain febrile conditions, such as *typhoid fever*, but in some infections seems to have a direct curative action. The work of Cohen (*Pa. M. J.*, 1919, p. 506; *J. Inf. D.*, 1917, xx, p. 313) in collaboration with Kolmer and Heist, furnishes strong scientific, as well as clinical, evidence of its value in *pneumonia*. They have shown that various salts of this drug have a strong germicidal action on the pneumococcus and that the blood of patients taking large doses of quinine acquires pneumococcicidal properties. The evidence of its value in *influenza* is based on purely clinical data. Garin (*Prog. M.*, 1918, xxxiii, p. 365) sent a questionnaire to a large number of hospitals in southern Europe immediately after the epidemic of 1918; 61 per cent. of these hospitals reported that none of their malarial patients who were receiving large doses of quinine developed influenza and 20 per cent. more that the influenza was distinctly milder among the malarial patients than in the rest of the hospitals. Sterling (*Pa. M. J.*, Sept., 1920) has collected from the literature reports of more than 3000 cases of malaria in various European hospitals, with only 17 cases of influenza and these of a very mild type, during the epidemic when the great majority of the other inmates of the hospital were infected. In acute *coryza* it has long been a standard remedy and undoubtedly if used early will often abort the attack. In *septicemia* it was formerly highly esteemed but has not seemed to maintain its early popularity. Moon (*Journ. of Infectious Diseases,* 1913, xiii, p. 165) presented evidence of a curative effect in hydrophobia in dogs, but his results have been called in question by Cumming (*Journ. of Infectious Diseases,* 1914, xv) and by Frothingham and Halliday (*Jour. Med. Research,* 1914, xxx). It appears also to be of use in *whooping-cough.*

Because of its restraining effect upon destructive metabolism as well as its effect as a bitter upon the stomach, quinine is a valuable remedy in the treatment of various forms of *malnutrition.* In *Graves's disease* it appears to have an effect not merely in restraining the excessive catabolism which is characteristic of this disorder, but also to have a general sedative influence on the nervous system. Some years ago on the theory that *chorea* was due to a lack of spinal inhibition H. C. Wood suggested the use of quinine in the treatment of this disorder, and in many cases it has proven of marked benefit. Through a similar line of reasoning its use was extended to the treatment of *nocturnal enuresis.* It is also recommended as an internal remedy by a number of authors in the treatment of various forms of skin disease, especially *psoriasis* and *urticaria;* in *lupus erythematosus* it has been used both internally and locally. Quinine has for years been employed more or less frequently in the management of *cardiac arrythmias* and with the recent studies of quinidine has had a renewal of popularity.

Brooke (*J. A. M. A.,* 1914, lxii) experimentally determined that quinine sulphate would kill ameba in solutions of 1 to 20,000, and employed it in the form of enemata in the treatment of amebic *dysentery* with satisfactory results. It has also been used with good results in amebic dysentery (see Leiva, *J. P. Ex. T.,* 1924, xxii, 467).

Quinine possesses marked local anesthetic powers and was at one time considerably used as a substitute for cocaine. For this purpose the hydrochloride of quinine and urea is generally preferred.

Because of the insolubility of basic quinine it was formerly believed that the alkaloid was absorbed only from the stomach, but Grosser (*Biochem. Zeit.,* 1907, viii, p. 98) has shown that even the insoluble preparations are completely absorbed. Hartmann and Zila (*A. E. P. P.,* 1918, lxxxiii, p. 221) confirm the fact that the insoluble salts of quinine are as well absorbed as the soluble. They also found that if the quinine was given by the mouth the proportion of the alkaloid in the blood remained practically constant for twelve to twenty-four hours but that if the drug was injected intravenously 90 per cent. of it had disappeared from the blood within thirty minutes. Apparently much of the drug is destroyed in the body as various investigators have succeeded in recovering only from 40 to 60 per cent. of the ingested dose from the excreta. According to Kerner, a portion escapes in an amorphous uncrystallizable form, and a second portion as a substance free from bitter taste, though crystallizable and having the fluorescence of quinine; for this substance he has proposed the name of *dihydroxyl-quinine.*

Elimination seems to be freest between the sixth and twelfth hours, and about two-thirds of that which is recovered from the urine is excreted within twenty-four hours of its ingestion.

The dose of quinine varies greatly according to the purpose for which it is used, as well as the susceptibility of the patient. When used for its tonic effect from three to five grains (0.2–0.32 Gm.) may be given three or four times a day. The antipyretic dose is from fifteen to twenty grains (1.0–1.3 Gm.). S. Solis Cohen has administered, in *pneumonia* with asserted good effects, twenty-five to thirty grains hypodermically (1.7–2.0 Gm.). In the milder forms of *malaria,* such as the ordinary *tertian fever* of temperate climates, from five to ten grains may be given every hour until the patient has taken twenty or thirty grains, and so timed that the last dose comes about an hour before the expected chill. In the tropical varieties of malaria, however, very much larger quantities are required, and in malignant types many authorities recommend to give as high as seventy-five to one hundred grains (5.0–6.5 Gm.) immediately. Such doses cannot be administered by mouth because they are likely to provoke emesis, and moreover, absorption is so slow as to be dangerous in these pernicious fevers. Under such circumstances the quinine may be given hypodermically. The most soluble of the official salts is the dihydrochloride, and by many is the salt of choice for injection, but it is likely to prove irritant because of its acid reaction. The double hydrochloride of quinine and urea is neutral in reaction and is soluble in less than its own weight of water; the 50 per cent. solution may be employed. If injected immediately beneath the skin, solutions of quinine salts are liable to produce local necrosis and ulceration and therefore should always be injected into the muscle substance either in the lumbar or gluteal regions. Extreme care in asepsis is essential in making these injections. A number of cases of *tetanus* have followed the injections of quinine, but McCampbell (*J. A. M. A.,* March 16, 1907) from his experiments concludes that there is no peculiar relation between the quinine and the tetanus germs, except that the spores may be carried in mechanically with the injection and the local necrosis offers a favorable place for their growth.

While it has been used occasionally by intravenous injection McCarrison and Cornwall (*Indian Jour. of Med. Research,* 1920, vi, p. 248) conclude from their experiments that the method is so dangerous as to be justifiable only in cases of great urgency.

Toxicology.—Even in the quantities employed for therapeutic purposes quinine frequently produces unpleasant symptoms. The most common of these is ringing in the ears often accompanied with a sensation of fullness in the head, and perhaps some obtunding of the sense of hearing. With the use of larger doses these symptoms are intensified; the deafness is very marked, disturbed vision may exist, and the flushed face, with the sense of distension in the head, may point towards a cerebral congestion, which is in some cases relieved by spontaneous epistaxis. In decided cinchonism, giddiness and staggering in walking are very common. After toxic doses, severe headache, delirium, stupor, complete deafness and blindness, dilated pupils, embarrassment of respiration, great weakness, convulsions, paralysis, and finally collapse, either comatose or delirious, may result. The deafness produced by large doses of quinine usually passes off rapidly; very rarely is there a permanent impairment of hearing. Amaurosis, with a peculiar ischemia of the retinal vessel, has in a small number of cases been produced by very large therapeutic doses of the alkaloid. (For report of cases of quinine amblyopia, see Weens, *Archives of Ophthalm.*, 1917.) Besides its effects on the brain, quinine sulphate sometimes occasions great gastric and intestinal irritation, marked by oppression of stomach, nausea, abdominal pains, vomiting, and purging. In general, these effects of excessive doses gradually pass off, although partial deafness often continues for several days, and sometimes much longer, and permanent deafness has resulted. It is capable of taking life, although enormous amounts of it are requisite for this. Several cases of recovery are recorded after the taking of an ounce by the stomach. Probably only a portion of the drug was absorbed. Five ounces taken in ten days have caused death.

In certain individuals even very small doses may produce toxic symptoms. In these cases the poisoning usually differs very markedly from the ordinary type described above, in most instances being manifest by eruptions on the skin which frequently closely simulate scarlet fever. (See H. C. Wood, Jr., *T. G.*, January, 1902.)

Dose, two to twenty grains (0.13–1.3 Gm.).

Off. Prep.—Oleatum Quininæ, *N. F.;* Syrupus Ferri, Quininæ et Strychninæ Phosphatum, *N. F.;* Syrupus Hypophosphitum Compositus, *N. F.;* Liquor Hypophosphitum Compositum, *N. F.;* Oleatum Quininæ, *N. F.*

QUININÆ ÆTHYLCARBONAS. U. S.

QUININE ETHYLCARBONATE Quin. Æthylcarb.
[Euquinine]

" $C_{20}H_{23}O_2N_2.CO_2.C_2H_5$." *U. S.*

Chininum Æthylo-carbonicum; Euchinina; Æthylcarbonas Chininæ.

Euquinine is manufactured by passing carbonyl chloride (phosgene) into dehydrated alcohol, rectifying the resulting chlorocarbonic ester and then allowing it to act upon a solution of anhydrous quinine in ether. The resulting quinine ethylcarbonate is subsequently purified by washing and crystallizing. The final purification is very difficult as crystallization is hard to induce.

Description and Physical Properties.—"White, fine, soft needles, usually matted together in fleecy masses. Quinine Ethylcarbonate is odorless and practically tasteless, but when masticated it slowly develops a slightly bitter taste. It darkens on exposure to light. Quinine Ethylcarbonate is only slightly soluble in water. One Gm. is soluble in 2 cc. of alcohol, 1 cc. of chloroform, and in about 10 cc. of ether, at 25° C. It is readily soluble in dilute acids.

"Quinine Ethylcarbonate melts between 89° and 91° C. Its saturated aqueous solution is slightly alkaline to litmus paper. Its solution in diluted sulphuric acid exhibits a blue fluorescence. To 5 cc. of an aqueous solution of Quinine Ethylcarbonate (1 in 1000), made with the aid of a slight excess of diluted sulphuric acid, add 2 or 3 drops of bromine T.S., and follow with 1 cc. of ammonia water: the liquid acquires a green color, due to the formation of thalleioquin. To about 0.2 Gm. of Quinine Ethylcarbonate add 2 cc. of sodium hydroxide T.S. and 5 cc. of iodine T.S., and gently warm the mixture: the odor of iodoform is evolved. Digest about 1 Gm. of Quinine Ethylcarbonate with 10 cc. of a 5 per cent. solution of potassium hydroxide in dehydrated alcohol: a white precipitate is gradually formed which effervesces with acids.

"Ash: not more than 0.2 per cent. Dried over sulphuric acid for twenty-four hours, the loss in weight does not exceed 2 per cent. (*water*). Dissolve 0.3 Gm. of Quinine Ethylcarbonate in 10 cc. of diluted nitric acid and 20 cc. of distilled water: ten cc. portions of this solution are not rendered turbid at once by the addition of a few drops of silver nitrate T.S. (*chloride*) or of barium chloride T.S. (*sulphate*).

"Preserve protected from light." *U. S.*

Euquinine gives the thalleioquin, but not the herapathite, reaction.

Uses.—Despite its sparing solubility, euquinine seems to be rapidly absorbed, Panegrosso and Gammarelli (*G. Osp.*, Oct. 18, 1897) finding that it appears within the urine within a half an hour after its ingestion. On the other hand, Kleine could only recover 17 per cent. of the quinine administered in this form from the urine. It is probable, although as far as we know not definitely proven, that euquinine is absorbed unchanged and broken up by the blood with the liberation of its quinine radical. At any rate, there is considerable evidence that it exercises the characteristic therapeutic effects of quinine. Von Noorden (*Cb. I. M.*, 1896) and Oberlach (*D. M. Ztg.*, 1897) have used it with satisfactory results in *pneumonia* and other febrile affections, and Panegrosso and Celli and Mori (*Cb. B.*, xxix) have employed it successfully in *malaria*. Several writers have found it useful in chlorotic *anemias*. It is probably more frequently used in *whooping cough* than in any other disease.

The special value of euquinine lies in its comparative tastelessness which makes it suitable for giving to children. It may be conveniently prescribed suspended in a flavoring syrup. Although theoretically it represents about 83.8 per cent. of quinine, it is generally administered in considerably larger doses than the older salts of the alkaloid.

Dose, as a tonic, three to six grains (0.2–0.4 Gm.), as an antimalarial, thirty to forty grains (2 to 2.6 Gm.) may be given daily.

QUININÆ BISULPHAS. U. S.

QUININE BISULPHATE Quin. Bisulph. [Quinine Acid Sulphate]

"$C_{20}H_{24}O_2N_2.H_2SO_4.7H_2O$." *U. S.*

Chininum Bisulfuricum; Quininæ Sulphas Acidus; Acid Quinine Sulphate; Bisulphas Quinicus; Chininum Sulfuricum, *Fr. Cod.;* Sulfate de Quinine Neutre, *Fr.;* Saures Chininsulfat, Chininbisulfat, *G.;* Bisolfato di chinina, *It.;* Sulfato quinico neutro, *Sp.*

This salt, although commonly called the "acid sulphate," is strictly speaking the neutral sulphate (see discussion under *Quininæ Sulphas*). It is made by suspending 100 Gm. of quinine sulphate in 500 Gm. of warm distilled water, and adding 115 Gm. of diluted sulphuric acid (U. S. P.), filtering and crystallizing. It has been introduced because of the great advantages in solubility that it possesses over the ordinary sulphate. It requires but 9 parts of water to dissolve it, while the sulphate requires 720.

Description and Physical Properties.—"Colorless, transparent or whitish, orthorhombic crystals or small needles. It is odorless, and has a very bitter taste. It effloresces on exposure to air, and turns yellow on exposure to light. One Gm. of Quinine Bisulphate is soluble in 9 cc. of water, 23 cc. of alcohol, 15 cc. of glycerin, 625 cc. of chloroform, and in 2500 cc. of ether, at 25° C. One Gm. is soluble in 0.7 cc. of boiling water and in 0.7 cc. of alcohol at 60° C.

"An aqueous solution of Quinine Bisulphate (1 in 20) is strongly acid to litmus paper, and has a blue fluorescence. Add 2 or 3 drops of bromine T.S. to 5 cc. of an aqueous solution of Quinine Bisulphate (1 in 1000), and then add 1 cc. of ammonia T.S.: the liquid acquires an emerald-green color, due to the formation of thalleioquin. Barium chloride T.S. produces in an aqueous solution of the salt a white precipitate, insoluble in hydrochloric acid.

"Quinine Bisulphate loses not more than 24 per cent. when dried to constant weight at 100° C. (*water*). Ash: not more than 0.05 per cent. A solution of 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*). Heat 0.3 Gm. of the salt with 3 cc. of sodium hydroxide T.S. on a water bath: the odor of ammonia is not evolved (*ammonium salts*). Dissolve 2.52 Gm. of Quinine Bisulphate in a mixture of 20 cc. of alcohol and 50 cc. of hot distilled water, and neutralize the solution with normal sodium hydroxide, using 2 drops of methyl red T.S. as indicator. Evaporate the solution to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for other *cinchona alkaloids* as directed under *Quininæ Sulphas.*

"Preserve in well-closed containers, protected from light." *U. S.*

The acid sulphate of quinine is much more freely soluble than the neutral sulphate and is therefore by many preferred. It has, however, no very real advantage, being inferior for hypodermic injection to the dihydrochloride or the double hydrochloride of quinine and urea because of its lesser solubility, and when given by the mouth the slight increase in solubility over the neutral salt is a matter of small importance. It represents 59.12 per cent. of quinine.

Dose, two to fifteen grains (0.13–1.0 Gm.).

QUININÆ DIHYDROCHLORIDUM. U. S. (Br.)

QUININE DIHYDROCHLORIDE Quin. Dihydrochl.

"$C_{20}H_{24}O_2N_2.2HCl$." *U. S.* "Acid Quinine Hydrochloride, $C_{20}H_{24}N_2O_2,2HCl$, is the acid hydrochloride of an alkaloid, quinine, obtained from the bark of various species of Cinchona." *Br.*

Quininæ Hydrochloridum Acidum, *Br;;* Acid Quinine Hydrochloride; Chlorurum Quinicum; Chininum Bihydrochloricum, *Fr. Cod.;* Chlorhydrate de Quinine Neutre, *Fr.;* Saures Chininhydrochlorid, Saures Chlorwasserstoffsaures Chinin, *G.*

This has been introduced on account of its remarkable solubility in water—*i.e.*, less than its own weight. It may be made by passing hydrochloric acid gas over dry quinine, but more conveniently by decomposing quinine bisulphate with barium chloride or by mixing a solution of neutral hydrochloride with one molecular proportion of hydrochloric acid and evaporating the solution at a gentle heat. It contains 81.63 per cent. of quinine.

Description and Physical Properties.—"A white, odorless powder, having a very bitter taste. One Gm. of Quinine Dihydrochloride is soluble in about 0.6 cc. of water and in 12 cc. of alcohol, at 25° C. It is slightly soluble in chloroform and very slightly soluble in ether.

"An aqueous solution of Quinine Dihydrochloride is strongly acid to litmus paper. Add 2 or 3 drops of bromine T.S. to 5 cc. of an aqueous solution of the salt (1 in 1000), and then add 1 cc. of ammonia T.S.: an emerald-green color is produced, due to the formation of thalleioquin. Silver nitrate T.S. added to an aqueous solution of the salt (1 in 20) produces a white precipitate, insoluble in nitric acid but soluble in ammonia T.S.

"Quinine Dihydrochloride loses not more than 3 per cent. when dried to constant weight at 100° C. (*water*). Ash: not more than 0.05 per cent. A solution of 0.1 Gm. of Quinine Dihydrochloride in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*). The addition of a few drops of diluted sulphuric acid to 10 cc. of an aqueous solution of the salt (1 in 20) produces no turbidity (*barium*). One Gm. of Quinine Dihydrochloride shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid. Dissolve 1.8 Gm. of Quinine Dihydrochloride in 10 cc. of distilled water, add a slight excess of ammonia T.S., shake out the mixture successively with 20, 10 and 10 cc. of chloroform, and evaporate the combined chloroform solutions to dryness on a water bath. Dissolve the residue in 25 cc. of alcohol, dilute the solution with 50 cc. of hot distilled water, add normal sulphuric acid (about 5 cc.) until the solution is acid, using 2 drops of methyl red T.S. as indicator, and neutralize the excess of acid with normal sodium hydroxide. Evaporate the liquid to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for *other cinchona alkaloids* as directed under *Quininæ Sulphas.*

"Preserve in well-closed containers, protected from light." *U. S.*

"A white amorphous powder. No odor; taste intensely bitter. Soluble in less than 1 part of *water*. Aqueous solution acid to *litmus*. Yields the *reactions* characteristic of chlorides. Yields not more than the slightest characteristic *reaction* for sulphates. 1 gramme dissolved in 20 millilitres of *water* requires for neutralisation not more than 5.0 millilitres of *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. Yields a green coloration when tested as described under 'Quininæ Hydrochloridum.' Loses not more than 3 per cent. of its weight when dried at 100° C. When 2 grammes are dissolved in 15 millilitres of *water*, the solution neutralised with *N/1 solution of sodium hydroxide*, mixed with 1 gramme of powdered non-effloresced *sodium sulphate*, and further treated as described under 'Quininæ Hydrochloridum,' the precipitate produced on the addition of *solution of ammonia* redissolves on rotating the tube (limit of other cinchona alkaloids). No appreciable ash." *Br.*

Uses.—The dihydrochloride is the most freely soluble of the official salts of quinine. For this reason it is frequently preferred for hypodermic injection. Because of its acid reaction, however, it is more likely to produce local irritation than the neutral salts.

Dose, two to ten grains (0.13–0.65 Gm.).

Off. Prep.—Ampullæ Quininæ Dihydrochloridum, *N. F.*

QUININÆ ET UREÆ HYDROCHLORIDUM. U. S.

QUININE AND UREA HYDROCHLORIDE Quin. et Urea. Hydrochl. [Quinine and Urea Chloride]

"Quinine and Urea Hydrochloride [$C_{20}H_{24}O_2N_2.HCl.CO(NH_2)_2.HCl.5H_2O$] contains not less than 58 per cent. of anhydrous quinine [$C_{20}H_{24}O_2N_2$]." *U. S.*

Quinine and Urea Muriate, Chininum Bimuriaticum Carbamidatum; Nikalgin; Quininæ Hydrochloro-carbamidum; Urea-quinine.

This salt, discovered by Kutais (1878), is best prepared by Rice's process. Seventy-nine parts of quinine hydrochloride are dissolved in 70 parts of hydrochloric acid (sp. gr. 1.050), the solution filtered, 12 parts of urea added, and the whole warmed until the liquid is clear. It is then set aside, that crystals may form. These are soluble in an equal weight of water, and also in strong alcohol, and are usually purified by recrystallization.

Description and Physical Properties.—"Colorless, translucent prisms, or a white, granular powder. It is odorless, and has a very bitter taste. One Gm. of Quinine and Urea Hydrochloride is soluble in 0.9 cc. of water and in 2.4 cc. of alcohol, at 25° C.

"An aqueous solution of Quinine and Urea Hydrochloride (1 in 20) is strongly acid to litmus paper. A solution of the salt in diluted sulphuric acid (1 in 1000) shows a blue fluorescence. Add 2 or 3 drops of bromide T.S. to 5 cc. of an aqueous solution of the salt (1 in 1000), and then add 1 cc. of ammonia T.S.: the liquid acquires an emerald-green color, due to the formation of thalleioquin. Add 2 cc. of colorless nitric acid to a cold solution of about 1 Gm. of the salt in 2 cc. of distilled water and cool the mixture at once to the temperature of melting ice: crystalline leaflets of urea nitrate are formed on standing. Collect the crystals in a funnel upon glass wool, wash them with about 5 cc. of a cold mixture of equal volumes of nitric acid and distilled water, and after draining, dissolve the crystals in a few cc. of distilled water: the addition of a few drops of mercuric nitrate T.S. to the urea nitrate solution, followed by sodium hydroxide T.S. to only a slightly acid reaction, produces a white precipitate. Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 20) a white precipitate, insoluble in nitric acid but soluble in ammonia T.S.

"Ash: not more than 0.05 per cent. A solution of 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*). Warm 10 cc. of an aqueous solution of the salt (1 in 20) with 5 cc. of sodium hydroxide T.S. to 50° C.: the odor of ammonia is not evolved at once (*ammonium compounds*). Dissolve about 3 Gm. of Quinine and Urea Hydrochloride in 30 cc. of distilled water in a separator, add 10 cc. of ammonia water, shake out the mixture successively with 30 and 20 cc. of chloroform, and evaporate the combined chloroform solutions to dryness on a water bath. Dissolve 1.5 Gm. of this residue in 25 cc. of alcohol, dilute the solution with 50 cc. of hot distilled water, add normal sulphuric acid (about 5 cc.) until the solution is acid, using 2 drops of methyl red T.S. as indicator, and neutralize the excess of acid with normal sodium hydroxide. Evaporate the liquid to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for *other cinchona alkaloids* as directed under *Quininæ Sulphas.*

"Preserve in well-closed containers, protected from light." *U. S.*

Assay.—"Dissolve about 0.5 Gm. of Quinine and Urea Hydrochloride, accurately weighed, in 5 cc. of distilled water in a separator, add 3 cc. of ammonia T.S., and shake the mixture with successive portions of 10, 5 and 5 cc., respectively, of chloroform or sufficient to completely extract the quinine. Evaporate the combined chloroform solutions on a water bath, dissolve the residue in 10 cc. of ether, evaporate to dryness and dry to constant weight at 100° C. The residue of anhydrous quinine ($C_{20}H_{24}O_2N_2$) so obtained corresponds to not less than 58 per cent. of the weight of the Quinine and Urea Hydrochloride taken." *U. S.*

Uses.—Quinine urea hydrochloride is the most suitable of all the official salts of the alkaloid for hypodermic administration on account of its free solubility and of its neutral reaction. It is, therefore, widely employed in the treatment of the severer types of *malaria,* where the drug must be given subcutaneously, as well as in other conditions where large doses are required. In 1907 Thibault (*Journ. of the Arkansas Medical Soc.,* Sept., 1907), from observing the local effects following the hypodermic administration of this salt, was led to investigate the anesthetic properties of the quinine salts and found that all of the soluble ones produced local anesthesia, if in concentration of greater than 1.5 per cent. For some time quinine and urea hydrochloride was quite extensively used as a local anesthetic. It has, however, the disadvantages that it does not easily penetrate mucous membranes and is therefore of low efficiency when applied as a wash, and when injected is liable to produce extensive sloughing (see *J. A. M. A.,* 1920, lxxv, p. 316). In recent years it has largely passed out of vogue.

Dose, two to ten grains (0.13–0.65 Gm.).

Off. Prep.—Ampullæ Quininæ et Ureæ Hydrochloridum, *N. F.*

QUININÆ HYDROBROMIDUM. U. S.

QUININE HYDROBROMIDE Quin. Hydrobr.

"[$C_{20}H_{24}O_2N_2.HBr + H_2O$]." *U. S.*

Quininæ Hydrobromas; Quinine Bromide; Basic Quinine Hydrobromide; Bromhydras Quininæ Neutralis; Chininum Monobromhydricum, *Fr. Cod.;* Bromhydrate Basique de Quinine; Monobromhydrate de Quinine, *Fr.;* Chininum Hydrobromicum; Chininhydrobromid; Bromwasserstoffsaures Chinin, *G.;* Bromuro Quinico Neutro, *Sp.*

This salt may be made by suspending 10 parts of quinine sulphate in 80 parts of water, boiling, and adding 3.4 parts of barium bromide dissolved in 20 parts of water, filtering, evaporating, and crystallizing. It may also be prepared by combining quinine alkaloid with hydrobromic acid in proper proportions, evaporating and crystallizing.

Description and Physical Properties.—"White, light, small needles, or scale-like crystals. It is odorless, has a very bitter taste, and effloresces on exposure to the air. One Gm. of Quinine Hydrobromide is soluble in 40 cc. of water, 1 cc. of alcohol, 7 cc. of glycerin, 0.6 cc. of chloroform, and in 23 cc. of ether, at 25° C. One Gm. is soluble in 3.2 cc. of water at 80° C.

"Add 2 or 3 drops of bromine T.S. to 5 cc. of an aqueous solution of Quinine Hydrobromide (1 in 1000), and then add 1 cc. of ammonia T.S.: an emerald-green color is produced, due to the formation of thalleioquin. To 5 cc. of an aqueous solution of Quinine Hydrobromide (1 in 50) add 1 cc. of sodium hydroxide T.S., and warm the mixture for a few minutes. Cool well, filter, acidulate the filtrate with dilute hydrochloric acid, add 1 cc. of chloroform and a few drops of chlorine T.S., and shake gently; the chloroform acquires a reddish-brown color.

"An aqueous solution of Quinine Hydrobromide (1 in 50) is neutral or only slightly alkaline to litmus paper and is not fluorescent except when mixed with an excess of diluted sulphuric acid. Dried to constant weight at 100° C., Quinine Hydrobromide loses not more than 5 per cent. (*water*). Ash: not more than 0.05 per cent. A solution of about 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*). One Gm. of Quinine Hydrobromide shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid. The addition of a few drops of diluted sulphuric acid to 10 cc. of a hot aqueous solution of the salt (1 in 20) produces no turbidity (*barium*). One Gm. of Quinine Hydrobromide dissolves completely in 7 cc. of a mixture of 2 volumes of chloroform and 1 volume of dehydrated alcohol (*inorganic salts*). Dissolve about 3 Gm. of Quinine Hydrobromide in 80 cc. of warm distilled water in a separator, add 10 cc. of ammonia T.S., shake out the mixture successively with 30 and 20 cc. of chloroform, and evaporate the combined chloroform solutions to dryness on a water bath. Dissolve 1.5 Gm. of this residue in 25 cc. of alcohol, dilute the solution with 50 cc. of hot distilled water, add normal sulphuric acid (about 5 cc.) until the solution is acid, using 2 drops of methyl red T.S. as indicator, and neutralize the excess of acid with normal sodium hydroxide. Evaporate the liquid to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for *other cinchona alkaloids* as directed under *Quininæ Sulphas.*

"Preserve in well-closed containers, protected from light." *U. S.*

Uses.—There is a wide-spread belief that this salt acts somewhat differently from the other preparations of quinine. The proportion of hydrobromic acid is, however, too small to exert any influence upon the system; ten grains of quinine hydrobromide represents less than two grains of hydrobromic acid. The salt has achieved a high reputation in the treatment of *Graves's disease,* and certainly in many cases will cause at least a temporary amelioration of many of the nervous manifestations of this disorder. According to Cohen, the most powerfully pneumococcicidal salt of quinine is the di-hydrobromide and of the official salts, the neutral hydrobromide is the most efficient in *pneumonia.* He recommends a beginning dose of twenty grains (1.3 Gm.) followed by five grains (0.3 Gm.) every three or four hours.

Dose, from two to ten grains (0.13–0.65 Gm.).

QUININÆ HYDROCHLORIDUM.
U. S., Br.

QUININE HYDROCHLORIDE Quin. Hydroch.

"$C_{20}H_{24}O_2N_2.HCl.2H_2O$." *U. S.* "Quinine Hydrochloride, $C_{20}H_{24}N_2O_2,HCl,2H_2O$, is the hydrochloride of an alkaloid, quinine, obtained from the bark of various species of Cinchona." *Br.*

Muriate of Quinine; Quinine Chloride; Quininæ Hydrochloras; Quinine Monohydrochloride; Chininum Monochlorhydricum, *Fr. Cod.;* Chlorhydrate de Quinine, *Fr.;* Chininum hydrochloricum, *P. G.;* Chininhydrochlorid; Salzsaures Chinin, *G.;* Cloridrato di chinina, *It.;* Cloruro Quinico, *Sp.*

This quinine salt may be readily prepared by treating the alkaloid with diluted hydrochloric acid, or by double decomposition between barium chloride and quinine sulphate.

Description and Physical Properties.—"White, silky, glistening needles. It is odorless, and has a very bitter taste. The salt effloresces when exposed to warm air. One Gm. of Quinine Hydrochloride is soluble in 16 cc. of water, 0.8 cc. of alcohol, 7 cc. of glycerin, 0.7 cc. of chloroform, and in 340 cc. of ether, at 25° C. One Gm. is soluble in 0.5 cc. of water at 80° C.

"Add 2 or 3 drops of bromine T.S. to 5 cc. of an aqueous solution of Quinine Hydrochloride (1 in 1000), and then add 1 cc. of ammonia T.S.: an emerald-green color is produced, due to the formation of thalleioquin. Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 20) a white precipitate, insoluble in nitric acid, but soluble in ammonia T.S.

"An aqueous solution of Quinine Hydrochloride (1 in 25) is neutral or not more than slightly alkaline to litmus paper, and is not fluorescent, except when highly diluted or when diluted sulphuric acid is added to it. Quinine Hydrochloride loses not more than 10 per cent. when dried to constant weight at 120° C. (*water*). Ash: not more than 0.05 per cent. A solution of 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*). One Gm. of the salt dissolves completely in 7 cc. of a mixture of 2 volumes of chloroform and 1 volume of dehydrated alcohol (*inorganic salts*). The addition of 5 drops of diluted sulphuric acid to 10 cc. of an aqueous solution of the salt (1 in 20) produces no turbidity (*barium*). One Gm. of Quinine Hydrochloride shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid. Dissolve about 2.5 Gm. of Quinine Hydrochloride in 60 cc. of distilled water in a separator, add 10 cc. of ammonia T.S., shake out the mixture successively with 30 and 20 cc. of chloroform, and evaporate the combined chloroform solutions to dryness on a water bath. Dissolve 1.5 Gm. of this residue in 25 cc. of alcohol, dilute the solution with 50 cc. of hot distilled water, add normal sulphuric acid (about 5 cc.) until the solution is acid, using 2 drops of methyl red T.S. as indicator, and neutralize the excess of acid with normal sodium hydroxide. Evaporate the liquid to dryness on a water bath, powder the residue, mix it in a test tube with 20 cc. of distilled water, and complete the test for *other cinchona alkaloids* as directed under *Quininæ Sulphas.*

"Preserve in well-closed containers, protected from light." *U. S.*

"White silky crystals, efflorescent in warm air. No odor; taste very bitter. Soluble in 36 parts of *water,* and in 2 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of chlorides. When to 10 millilitres of an aqueous solution (1 in 1000) 0.5 millilitre of *solution of bromine* and, after well shaking, 1 drop of *strong solution of ammonia* are added, a deep green coloration is produced. When 2 grammes are dissolved in a warm mortar in 20 *millilitres of water* at 60° C., 1 gramme of powdered non-effloresced *sodium sulphate* added, the mixture triturated, cooled, allowed to stand at exactly 15° C. for half an hour with occasional stirring, the crystals of quinine sulphate pressed, and the expressed liquid filtered, 5 millilitres of this filtrate, transferred to a dry test-tube and brought to a temperature of 15° C., yield, on the gradual addition of 6 millilitres of *solution of ammonia,* also at a temperature of 15° C., a precipitate which redissolves on rotating the tube (limit of other cinchona alkaloids). Dissolves in *sulphuric acid* and in *nitric acid* without coloration. 1 gramme dissolves in 7 millilitres of a mixture of 2 volumes of *chloroform* and 1 volume of *absolute alcohol.* Loses not more than 9.1 per cent. of its weight when dried at 100° C. Yields no characteristic *reactions* for barium or for sulphates. No appreciable ash." *Br.*

Only the compounds of quinine with the oxy-acids show the fluorescence in acid solution, none of the compounds of the haloid acids showing this reaction.

Quinine hydrochloride has a decided advantage over the sulphate in its greater solubility in water. It is, however, less soluble than the acid quinine hydrochloride. It represents 90.92 per cent. of anhydrous quinine.

Dose, two to ten grains (0.13–0.65 Gm.).

QUININÆ SULPHAS. U. S., Br.

QUININE SULPHATE Quin. Sulph.

"$(C_{20}H_{24}O_2N_2)_2.H_2SO_4$ (with 7 or $8H_2O$)" *U. S.* "Quinine Sulphate $(C_{20}H_{24}N_2O_2)_2,H_2SO_4,7\frac{1}{2}H_2O$, is the sulphate of an alkaloid, quinine, obtained from the bark of various species of Cinchona." *Br.*

Sulfas Quinicus; Basic Sulphate of Quinia; Chininum Subsulfuricum, *Fr. Cod.;* Sulfate Basique de Quinine, *Fr.;* Chininum Sulfuricum, *P. G.;* Chininsulfat; Schwefelsaures Chinin, *G.*; Solfato di chinina, *It.;* Sulfato quinico basico, *Sp.*

No process is given in the U. S. Pharm. for preparing quinine sulphate; that of the U. S. P., 1870, will be found in detail in the *U. S. D.*, 17th ed., p. 1141. The process, briefly stated, is to exhaust cinchona bark by boiling with water acidulated with hydrochloric acid and adding milk of lime in excess. The quinine is precipitated with lime, and the dried precipitate digested with boiling alcohol; the alcoholic solution of quinine is evaporated, and the mass dissolved in water acidulated with sulphuric acid. The hot solution is treated with animal charcoal to decolorize it, and then set aside to crystallize. Commercially the process is as follows:

The bark is powdered finely and then mixed with about ⅓ of its weight of finely sifted slaked lime and moistened thoroughly with a 5 per cent. sodium hydroxide solution. It is then extracted with hot high boiling kerosene in vessels provided with powerful stirrers and heated by steam; the selection of a kerosene of proper character is of great importance. Three successive extractions are made. The kerosene dissolves out all of the alkaloids, which are then converted into neutral sulphates in lead lined vessels by the careful addition of a weak sulphuric acid solution. Quinine sulphate crystallizes out first and is purified by decolorization with animal charcoal and recrystallization. The other alkaloids are precipitated by adding alkali to the mother liquor from the quininic and are separated by the use of specific solvents for each alkaloid.

In this country this is the substance usually intended by the term "quinine." Strictly speaking it is not the neutral sulphate although commonly so regarded. It contains two basic radicals to one acidic and is therefore a *diquinine sulphate* or a *quinine subsulphate;* in the Codex it is so denominated and the term "Chininum Sulfuricum" is applied to the salt usually known as the bisulphate. There are at least three quinine sulphates that have been obtained, of which two are now official. The first of these,

$$(C_{20}H_{24}N_2O_2)_2H_2SO_4 + 7H_2O$$

is a "*diquinic sulphate,*" but is the official salt known as quinine sulphate, or *Quininæ Sulphas,* U. S.; the second, formed by dissolving this first in dilute sulphuric acid, has the formula

$$C_{20}H_{24}N_2O_2,H_2SO_4 + 7H_2O$$

and is the official quinine bisulphate, or *Quininæ Bisulphas,* U. S.; while the third, a still more acid sulphate,

$$C_{20}H_{24}N_2O_2,2H_2SO_4 + 7H_2O$$

may be obtained from a solution of quinine in excess of diluted sulphuric acid. This salt is not official.

Description and Physical Properties.—"Hard, prismatic monoclinic needles or white, silky, light, flexible, glistening crystals, making a very light and easily compressible mass. It is odorless, and has a persistent, very bitter taste. It effloresces rapidly when exposed to dry air or when heated to 50° C., losing all but two molecules of its water of crystallization and becoming lusterless. When exposed to light, it acquires a brown tint. One Gm. of Quinine Sulphate is soluble in 725 cc. of water, 107 cc. of alcohol, and in 30 cc. of glycerin, at 25° C. One Gm. is soluble in 47 cc. of water at 80° C. and in about 12 cc. of alcohol at 60° C. It is slightly soluble in chloroform and in ether, but is freely soluble in a mixture of 7 volumes of chloroform and in 4 volumes of dehydrated alcohol.

"A saturated aqueous solution of Quinine Sulphate, when acidulated with diluted sulphuric acid, develops a vivid blue fluorescence. Add 1 or 2 drops of bromine T.S. to 5 cc. of an aqueous solution of the salt (1 in 1000) and then add 1 cc. of ammonia T.S.: the liquid acquires an emerald-green color, due to the formation of thalleioquin. Barium chloride T.S. produces in an aqueous solution of the salt a white precipitate, insoluble in hydrochloric acid.

"A saturated aqueous solution of Quinine Sulphate is neutral or not more than slightly alkaline to litmus paper. Quinine Sulphate loses not more than 16.2 per cent. when dried to constant weight at 100° C. (*water*). Ash: not more than 0.05 per cent. A solution of 0.1 Gm. of the salt in 2 cc. of sulphuric acid is not darker than light yellow (*readily carbonizable substances*). One Gm. of the salt dissolves completely when heated to 50° C. in 7 cc. of a mixture of 2 volumes of chloroform and 1 volume of dehydrated alcohol, and the solution remains clear on cooling (*inorganic salts*). Dry Quinine Sulphate (which must be neutral or slightly alkaline to litmus paper) at 50° C. for two hours, and then agitate 1.8 Gm. of the dried salt with 20 cc. of distilled water at 65° C. for half an hour. Allow the mixture to cool to 15° C., macerate it at this temperature for two hours with occasional shaking, and then filter it through a filter paper of a diameter from

8 to 10 cm. Transfer 5 cc. of this filtrate to a test tube and mix it gently (without shaking) with 6 cc. of ammonia T.S., which must contain not less than 10 per cent. and not more than 10.2 per cent. of NH_3, have a temperature of 15° C., and be added at once. A clear liquid is produced (*other cinchona alkaloids*).

"Preserve in well-closed containers, protected from light." *U. S.*

"Small, light, white, silky crystals. No odor; taste intensely bitter. Soluble in 800 parts of *water*, and in 65 parts of *alcohol* (90 per cent.). Aqueous solution exhibits a blue fluorescence. Entirely soluble in *water* acidified with a mineral acid. Yields the *reaction* characteristic of sulphates. When to 10 millilitres of an aqueous solution (1 in 1000) 0.5 millilitre of *solution of bromine* and, after well shaking, 1 drop of *strong solution of ammonia* are added, a deep green coloration is produced. Exposed to dry air the crystals effloresce until the water of crystallization is reduced from 7½ molecules to 2 molecules. Aqueous solution yields with *solution of ammonia* a precipitate soluble in *ether*. When 2 grammes, weighed after drying at 50° C., are digested at 60° to 65° C. in a stoppered test-tube with 20 millilitres of *water* for half an hour, repeatedly shaken, then allowed to cool to 15° C., kept at that temperature for half an hour, stirred from time to time, the crystals pressed, and the expressed liquid filtered, then 5 millilitres of this filtrate, transferred to a dry test-tube and brought to a temperature of 15° C., yield, on the gradual addition of 6 millilitres of *solution of ammonia*, also at a temperature of 15° C., a precipitate which redissolves on rotating the tube (limit of other cinchona alkaloids). 1 gramme dissolves in 7 millilitres of a mixture of 2 volumes of *chloroform* and 1 volume of *absolute alcohol*. No appreciable ash." *Br.*

The acid quinine salts possess fluorescent properties with the exception of those of the haloid acids. The fluorescence is recognizable in a solution containing only one part of quinine in 100,000 parts of water. It has also been discovered that the presence of acetphenetidin conceals the fluorescence of sulphuric acid solutions of quinine. The diluted acids, and tartaric and oxalic acids in excess, dissolve the sulphate easily. With an additional equivalent of sulphuric acid it forms another sulphate, which is more soluble in water than the official salt, and crystallizes from its solution with much greater difficulty.

Quinine sulphate, owing to the ease with which it parts with its water of crystallization, is apt to mislead those who seek to determine its quality. Forty samples examined by A. J. Cownley showed results varying from 8.1 to 15.95 per cent. of water of crystallization. He recommends for adoption in the Pharmacopœia the air-dried salt, which contains two molecules of water (4.6 per cent.), as being constant in composition. Farr and Wright confirm Cownley's views, and object to "anhydrous" quinine sulphate, which has been proposed by some chemists as the standard, because it has the opposite fault of absorbing moisture. (*P. J.*, 1896, 525; also *P. J.*, 1897, 203.)

The official test is probably the most reliable of all to establish a maximum limit of small quantities of other cinchona alkaloids. It is a modification of Kerner's (see *U. S. D.*, 19th edition, page 1045), and admits the presence of a trace of other alkaloids. This certainly is as pure as the quinine sulphate need be. To separate the remaining trace of alkaloids entirely would require too great an expense, in fact it would more than double the cost of the salt.

Quinine sulphate is decomposed by the alkalies, their carbonates, and the alkaline earths. In solution it affords white precipitates with potassium and sodium hydroxides, and ammonia, which are partly soluble in an excess of alkali. Quinine sulphate is also precipitated by astringent infusions, the tannic acid of which forms a white insoluble compound with quinine. The soluble salts of lead and of barium occasion precipitates; and that produced by the salts of barium is insoluble in the acids. The soluble salts of acetic, oxalic, tartaric, and gallic acids occasion more or less precipitation with solution of quinine sulphate without excess of acid. A solution of chlorine added to a solution of quinine sulphate and followed by the addition of ammonia water occasions an emerald-green color and, in certain proportions, the deposition of a green precipitate. The green compound has received the name of *thalleioquin*. The drop of ammonia should be put in without agitation. According to Flückiger, 1-5000th part of quinine can thus be found. With bromine instead of chlorine the test is more delicate. Flückiger states that 1-20,000th part of the alkaloid can be detected. (See a paper by C. F. Zeller, ***A. J. P.***, 1880, p. 385.) Some improvements in the thalleioquin test were suggested by LaWall (*A. J. P.*, 1912, p. 484), to obviate the difficulties frequently encountered, which were found to be principally due to oxyacids in the chlorine solution. This solution is frequently not freshly nor properly prepared. A much more delicate reaction is produced by the use of a reagent made by dissolving 0.5 Gm. of potassium bromate and 10 cc. of hydrochloric acid in enough water to make 100 cc. With this reagent it was found possible (when using volumes as large as 100 cc. of the solution being tested) to detect quinine in dilutions of 1-200,000. The procedure is as follows: Take 100 cc. of suspected solution, add 5 to 10 drops of the reagent, agitate well and immediately add 10 drops of stronger ammonia water and mix thoroughly.

F. S. Hyde (*Proc. A. Ph. A.*, 1897, 704) states that a solution of calcium hypochlorite gives more satisfactory results in the thalleioquin test than either chlorine or bromine water, the results being more certain and brilliant. If, previously to the use of ammonia in the chlorine test, a concentrated solution of potassium ferrocyanide be added, a dark red color is produced, which persists for several hours, but ultimately passes into green. This does not take place with cinchonine; and, though quinidine sulphate gives the same red color, this does not disappear as with the quinine salt, but is persistent. (Schwartzer, *J. P. C.*, 4e sér., iii, 475.) Quinine sulphate gives a reddish-brown precipitate with iodine dissolved in a solution of potassium iodide. (See *Herapathite* under *Quinina.*) A delicate reagent for quinine has been proposed by Giessa and Halberkann (*B. P. Ct.* through *Ph. Era*, 1919, lii, 100). It consists of potassium iodide 10 parts, mercuric chloride twenty-seven parts, glacial acetic acid 2.5 parts and water 200 parts. It is said to give a turbidity with 1 part of quinine in 200,000 parts of water. To detect quinine in urine with this reagent, the alkaloid should first be extracted with ether. Kolthoff (*D. C.*, 1919, lxiii, 381) has found that the well known *Kerner's test* for differentiating other cinchona alkaloids from quinine gives satisfactory results only when applied to quinine sulphate and that it is absolutely unreliable when applied to the bisulphate, hydrochloride or the alkaloid itself. No satisfactory method has yet been found for the quantitative separation of quinine and strychnine, for application to elixirs and similar preparations containing both alkaloids. For a discussion of the methods that have been proposed, see a paper by A. R. Bliss (*J. A. Ph. A.*, 1919, viii, 804). For valuable comments on quinine sulphate tests, see *Proc. A. Ph. A.*, 1897, 705.

Adulterations.—Quinine sulphate has often been adulterated. The effects of adulteration may be produced by the variable quantity of water which quinine sulphate may contain, without any observable alteration in its sensible properties. It is easy to detect and to obviate this natural sophistication by exposing a suspected specimen to a heat of 115° C. The loss of weight will indicate the quantity of water not essential to the salt. This is now covered by the official limiting test for the amount of moisture. Calcium sulphate, and other alkaline or earthy salts, gum, sugar, mannite, starch, stearin, caffeine, salicin, phlorizin, and the cinchonine sulphate, and sulphates of other cinchona alkaloids, are among the substances which are said to have been fraudulently added in former times, but such gross adulterants have disappeared from the market product. It is sometimes replaced by or mixed with other cinchona alkaloids. According to W. A. Puckner (*West. Drug.*, 1896, 393), nearly pure crystallized calcium sulphate in fine needle-shaped crystals has been exploited as tasteless quinine sulphate under the name of *flora china.*

Uses.—The fatuous persistence with which the American profession and public continue to prefer this salt is one of the peculiar problems of crowd psychology. It contains less quinine than the hydrochloride, representing 85.55 per cent. of anhydrous quinine, is practically insoluble and has no possible advantages. (See *Quinina.*)

Dose, two to ten grains (0.13–0.65 Gm.).

QUININÆ TANNAS. U. S.

QUININE TANNATE Quin. Tann

"Quinine Tannate is a compound of quinine with tannic acid, of somewhat varying composition, corresponding to not less than 30 per cent. and not more than 35 per cent. of anhydrous quinine [$C_{20}H_{24}O_2N_2$]." *U. S.*

Tannate of Quinine; Tannas Quinicus; Chininum Tannicum.

Quinine tannate may be prepared by precipitating one part of quinine sulphate, dissolved in thirty parts of water acidulated with a few drops of sulphuric acid, with a solution of three parts of tannic acid dissolved in thirty parts of cold water, and then washing and drying the precipitate. For other methods of preparing the tannate, see *West. Drug.*, 1893, 352; *Ph. Centralh.*, 1894, 155; *Proc. A. Ph. A.*, 1894, 675. It has the advantage of possessing little taste, but doubts have been repeatedly expressed about its efficiency.

Description and Physical Properties.—"A pale yellow or yellowish-white, amorphous powder. It is odorless and tasteless, or has not more than a slightly bitter, astringent taste. Quinine Tannate is only slightly soluble in water, chloroform, and ether. It is somewhat more soluble in alcohol.

"When heated it melts to a purplish, viscous mass. A saturated aqueous or alcoholic solution of Quinine Tannate is colored blue-black by ferric chloride T.S. The alkaloid obtained in the assay responds to the identity tests under *Quinina.*

"Quinine Tannate loses not more than 10 per cent. when dried to constant weight at 100° C. (*water*). Ash: not more than 0.3 per cent. Shake 0.5 Gm. of Quinine Tannate with 50 cc. of distilled water and 1 cc. of nitric acid for five minutes, and filter: a 10 cc. portion of the filtrate is not colored by 1 cc. of hydrogen sulphide T.S. (*heavy metals*). Other 10 cc. portions of the filtrate show no more *chloride* than corresponds to 0.5 cc. of fiftieth-normal hydrochloric acid and no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid. Shake 1 Gm. of Quinine Tannate with 25 cc. of dehydrated ether for five minutes, filter, and wash the filter with 10 cc. of dehydrated ether. Evaporate the combined filtrate and washings and dry at 100° C.: the residue does not exceed 1 per cent. (*uncombined quinine*).

"Preserve in well-closed containers, protected from light." *U. S.*

Assay.—"Transfer to a separator about 0.5 Gm. of Quinine Tannate, accurately weighed, add 10 cc. of distilled water and 10 cc. of ammonia T.S., and shake at first with 20 cc. of ether, then with three successive 10 cc. portions of ether. Evaporate the combined ethereal liquids and dry the residue to constant weight at 100° C. The weight of the anhydrous quinine ($C_{20}H_{24}O_2N_2$) so obtained corresponds to not less than 30 and not more than 35 per cent. of the weight of the Quinine Tannate taken." *U. S.*

Uses.—This is one of the least efficient of the quinine preparations; not only does it contain less than one-half the amount of alkaloid in the other salts but because of its slow hydrolysis and consequently delayed absorption has a still lower index of therapeutic activity. It is useful, however, as a means of administering quinine to young children, who are not able to swallow pills, because of its comparative tastelessness. It has to a considerable extent been replaced, even for this purpose, by some of the synthetic compounds such as the ethylcarbonate.

Dose, for adults, three to fifteen grains (0.2–1 Gm.).

RENNINUM. N. F.

RENNIN

"The partially purified milk-curdling enzyme obtained from the glandular layer of the stomach of the calf, *Bos taurus* Linné (Fam. *Bovidæ*), and capable of coagulating not less than 25,000 times its weight of fresh milk. Rennin of a higher coagulating power may be brought to the standard by admixture with sodium chloride and lactose. Rennin deteriorates rapidly and must be kept in well-stoppered, amber-colored bottles, and stored in a cool place." *N. F.*

Lab; Käselab, *G.;* Caillete, Présure, *Fr.*

Whether the milk-curdling enzyme of the gastric juice is distinct from pepsin is not certain although the majority of physiologists appear to so regard it. *Rennet* is an aqueous or vinous infusion of the dried stomach of the calf, though that of the sheep or other animal would probably answer the same purpose. It is much used, as every one knows, for curdling mild, a property which it owes to a portion of the gastric secretion, retained in the mucous tissue of the stomach. Such a solution was formerly recognized by the N. F. under the title *Liquor Seriparus.*

The N. F. recognizes a dried preparation containing the milk-curdling ferment. It is described as follows:

Description and Physical Properties.—"Rennin occurs as a grayish white or yellowish white powder, or as pale yellow grains or scales having a characteristic and slightly saline taste and a peculiar, not unpleasant odor. It is slightly hygroscopic. It is slowly soluble in water and in diluted alcohol, the solutions being more or less opalescent.

"When mounted in water or diluted alcohol and examined microscopically, it shows no cellular structure, and no blue coloration is produced on the addition of iodine T.S.

"**Assay.**—Mix 0.1 Gm. of Rennin with 50 cc. of distilled water by gentle stirring or trituration in a mortar (vigorous shaking or violent agitation must be avoided) and allow the liquid to stand for exactly 15 minutes. Place 50 cc. of cow's milk, having an acidity of not less than 0.14 per cent. nor more than 0.15 per cent., calculated as lactic acid (increasing the acidity of the milk, if low, by the addition of the required amount of lactic acid, or reducing it, if high, by the addition of the required quantity of sodium hydroxide) in a beaker about 12 centimeters high and 5 centimeters in diameter. Warm the milk rapidly on a water-bath to 43° C., add 1 cc. of the Rennin solution and stir the mixture slowly for 10 seconds. Maintain the temperature at 43° C. until the milk begins to thicken, as shown by a distinctly convex surface when the beaker is tipped to an angle of about 45°. This thickening must take place within 10 minutes from the time of the addition of the rennin solution. An additional 30 seconds on the water-bath produces a firm curd. The acidity of the milk used is ascertained by titrating 50 cc. of the undiluted milk with normal solution of sodium hydroxide, using phenolphthalein T.S. as indicator." *N. F.*

George Ellis prepared *rennet wine* as follows: Take the stomach of a calf immediately after the animal has been killed, cut off and reject about three inches of the upper or cardiac portion, slit the stomach longitudinally, wipe it gently with a dry napkin so as to remove as little of the clean mucous as possible, then cut it into small pieces, the smaller the better, put it into a common wine bottle, fill the bottle with good sherry, and let it stand corked for three weeks. It is known to be good if a teaspoonful will coagulate half a pint of milk in two minutes at 37.7° C.

Rennin was admitted to the National Formulary for the purpose of using it as an ingredient in making Compound Elixir of Pepsin and Rennin, which is chiefly used as a vehicle for nauseous medicines.

Off. Prep.—Elixir Pepsini et Rennini Compositum, *N. F.*

RESINA. U. S., Br.

ROSIN Resin. [Colophony]

"The residue left after distilling the volatile oil from the oleoresin obtained from *Pinus palustris* Miller and from other species of *Pinus*

(Fam. *Pinaceæ*)." *U. S.* "The residue left after the distillation of the oil of turpentine from the crude oleo-resin (crude turpentine) of various species of Pinus." *Br.*

Colophone, Arcanson, Brai sec, *Fr.;* Colophonium, *P. G.;* Kolophonium, Geigenharz, Fichtenharz, *G.;* Colofonia, Ragia, Pece greca, *It.;* Colofonia, Pez griega, *Sp.*

After the distillation of the volatile oil from turpentine (see *Terebinthina*), a resinous matter remains, which on the continent of Europe is called *colophony,* but with us is commonly, and now officially, known by the name of *rosin.* It is the *Resina* of the U. S. and British Pharmacopœias. It is sometimes called *resina flava,* or *yellow rosin.* When this, in a state of fusion, is strongly agitated with water it acquires a distinct appearance, and is denominated *resina alba,* or *white rosin.* The ports from which rosin is shipped are Wilmington, N. C., Charleston, S. C., and Savannah, Ga.

Common or *yellow rosin,* in its purest state, is beautifully clear and pellucid, but much less so as usually found in commerce. Its color is yellowish-brown with a tinge of olive, and more or less dark, according to its purity and the degree of heat to which it has been exposed in its preparation. Sometimes it is almost black. It is rather heavier than water. It is completely liquid at 152.5° C., begins to emit bubbles of gas at 157.5° C., and is decomposed at a red heat.

Description and Physical Properties.—"Sharply angular, translucent, amber-colored fragments, frequently covered with a yellow dust, fracture brittle at ordinary temperatures, shiny and shallow-conchoidal. The odor and taste are slightly terebinthinate. Rosin is freely soluble in alcohol, ether, benzene, glacial acetic acid, and in fixed or volatile oils. It is also soluble in dilute solutions of the fixed alkali hydroxides.

"Its alcoholic solution is acid to litmus paper. Specific gravity: 1.07 to 1.09 at 25° C. Rosin is easily fusible and burns with a dense yellowish smoke. Ash: not more than 0.05 per cent. Acid number: not less than 150." *U. S.*

"Translucent, of a light amber color, compact, brittle, pulverisable; fracture shining; odor and taste faintly terebinthinate. Soluble in *alcohol* (90 per cent.), in *ether, benzene,* and *carbon disulphide.* Readily fusible; burns with a dense yellow flame and much smoke, leaving no appreciable ash." *Br.*

Composition.—Rosin consists chiefly of several isomeric forms of the anhydride of *abietic acid* (*abietinic acid*), which has the formula $C_{19}H_{28}O_2$. Jean, however (*Chem. News,* xxvi, 207), has separated two other resinoid substances in addition to abietic acid. Lewkowitsch (*Chem. Analysis of Oils,* etc., 2d ed., 236) states that rosin also contains varying quantities of unsaponifiable hydrocarbons, due to the partial breaking up of the acid on distilling the pine rosin. This may vary from 5 to 9 per cent. in the American rosin. For a paper on abietic acid by Mead and Kremers, see *Proc. A. Ph. A.,* 1893, 198. By shaking coarsely powdered rosin with dilute alcohol and warming, it is converted into *abietic acid.* Cohn (*Ph. Wb.,* 1917, liv, 767) has done some research recently which indicates that rosin is simply impure abietic acid. Knecht and Hibbert (*J. P. C.,* 1919, xx, 324) have obtained from American rosin dextrorotatory *pimaric acid,* melting point 161°, and from French rosin a lævorotatory *pimaric acid* of the same melting point. Rosin, when it is boiled with alkaline solutions, forms greasy salts of abietic acid, the so-called rosin soaps which are used in admixtures with other soaps. As the acid is dibasic, these salts contain two atoms of alkali metal in combination. Rosin, distilled by itself, yields the so-called "rosin-oil," of which two fractions are taken separately—the first that distilling under 360° C., and the second that over 360° C.—and some 31 per cent. of fixed gases. The lighter fraction is known commercially as *rosin essence,* and is, according to Renard (*J. Chem. S.,* Aug., 1884, p. 843), composed of hydrocarbons, representing almost all series, from the paraffin series to the terpenes, including pentane and hexane, amylene and hexylene, toluene, xylene, and cumene, the tetra- and hexa-hydrides of all three of these, terebenthene and cymene. Several aldehydes and acids of the fatty series, such as isobutyric and valeric, were also recognized. The heavier fraction, or *rosin oil* in the stricter sense of the word, is composed of polymers of the hydrocarbons C_nH_{2n-2}, which readily resinify by the absorption of oxygen. This accounts for the use of rosin oil as an adulterant of linseed oil in the manufacture of printer's ink. When distilled with superheated steam, rosin yields benzene and toluene. *Sylvic acid,* formerly considered to be a constituent of rosin, is now regarded as abietic acid. Propionic acid has, according to Renard, been obtained in abundance from the tar produced by the destructive distillation of rosin. (*A. Pharm.,* 1886, p. 939.)

A. Tschirch and B. Studer determined the nature of the constituents of American rosin. The sample under examination (presumably from *P. palustris*) was completely soluble in the ordinary solvents for resin, including petroleum benzin, in which some other varieties of rosin are only partly soluble. Its alcoholic solution is strongly acid in reaction. Its sp. gr. at 15° C. was 1.090. Its composition was proved to be as follows:

1. Acids soluble in ammonium carbonate: *α-abietinic* (*abietic*) *acid,* $C_{19}H_{28}O_2$, forming an insoluble lead salt, 30 per cent.; *β-abietinic acid,* $C_{19}H_{28}O_2$, not forming a lead salt, 22 per cent. 2. Acid soluble in sodium carbonate: *γ-abietinic acid,* $C_{19}H_{28}O_2$, insoluble in ammonium carbonate, 31.06 per cent. 3. Volatile oil, 0.4 to 0.7 per cent. 4. Resene, 5 to 6 per cent.

The impurities amounted only to 0.1 per cent., the loss in operation, however, to 10 per cent.

Fahrion having proposed a method for the differentiation of different rosins, based upon their relative solubility in petroleum benzin, the authors determined the amount of solvent necessary to dissolve 1 Gm. of rosin, freshly powdered, and old powder; also abietinic acids and the resene in petroleum benzin, with the following results:

Rosin, old powder, 1 Gm. required	400 cc.
Rosin, fresh, 1 Gm. required	60 cc.
α-Abietinic acid, 1 Gm. required	500 cc.
β-Abietinic acid, 1 Gm. required	100 cc.
γ-Abietinic acid, 1 Gm. required	100 cc.
Resene	50 cc.

These results show that all the resin-acids, as well as the rosin, are more or less soluble in petroleum benzin, and that fresh rosin is more readily soluble than the isolated acids, a peculiarity which has also been noticed in the case of other bodies. On the other hand, old rosin is much less soluble in petroleum benzin than is fresh rosin. (*A. Pharm.*, Oct., 1903, 495–522.)

A new and very interesting class of derivatives from colophony or rosin has been prepared by Eugen Schaal, of Feuerbach, Germany, and introduced into commerce under the name of *ester gums*. These are the *glyceryl, methyl,* and *ethyl esters of abietic acid,* made by heating the resin acid and the alcohol under pressure until molecular condensation takes place. The product is then distilled off under reduced pressure. These "ester gums" are being used to advantage as substitutes for copal, damar, and kauri gum in varnish making.

Uses.—Rosin is important as an ingredient of ointments and plasters, but is rarely used internally. According to Olmstead, it has the property of preventing the oxidation of fatty substances, and thus contributes to the preservation of ointments. (*A. J. P.*, xxii, 325.)

RESINA IPOMŒÆ. U. S. (Br.)

RESIN OF IPOMEA Res. Ipom.

"Scammony Resin is a mixture of resins obtained from Scammony Root or from Orizaba Jalap Root." *Br.*

Scammoniæ Resina, *Br.;* Scammony Resin.

"Ipomea, in coarse powder, 1000 Gm.; Alcohol, Water, each, a sufficient quantity. Moisten the Ipomea with sufficient alcohol, pack it in a cylindrical percolator, and add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding alcohol until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol until the percolate is reduced to the consistence of thin syrup, and pour this slowly, with constant stirring, into 1000 cc. of hot water. When the precipitate has subsided, decant the supernatant liquid, wash the precipitated resin twice by decantation with fresh portions of 1000 cc. each of hot water, drain off the water thoroughly, and dry the Resin on a water bath." *U. S.*

"Exhaust the coarsely powdered Root with Alcohol (90 per cent.). Recover most of the alcohol by distillation; pour the concentrated solution thus obtained into eight times its volume of Distilled Water; allow the resin that separates to subside, wash it with Distilled Water, and dry at a gentle heat." *Br.*

Because of the almost complete disappearance from the market of genuine scammony resin, the Br., 1914, permitted the substitution of the resin of the so-called "Mexican scammony." This, in our opinion, is an unfortunate procedure because there can be no doubt as to the difference in the composition of these two resins and there is no satisfactory evidence of their therapeutic interchangeability. The U. S. X faced with a similar problem has solved it, we believe, more satisfactorily by dropping altogether scammony and substituting the Ipomea resin.

Genuine scammony resin was originally prepared by incising the root and evaporating the milk juice which exuded. As thus collected it was really a gum-resin and formed spontaneous emulsions. This was known officially in the Pharmacopœia as *Scammonium,* and popularly called *Virgin Scammony.* Because of the adulteration practised by the natives in collecting and preparing this substance, both of the Pharmacopœias adopted the plan of importing whole root and preparing the resin by extracting with alcohol.

Description and Physical Properties.—"Translucent masses or fragments, of a brown color, breaking with a glossy, resinous fracture; odor characteristic. Resin of Ipomea is soluble in alcohol and in chloroform; from 80 to 90 per cent is soluble in ether, and less than 5 per cent. is soluble in petroleum benzin.

"Ash: not more than 0.5 per cent. Resin of Ipomea is slowly soluble in five times its weight of ammonia T.S. and in potassium hydroxide T.S., yielding a somewhat cloudy solution which does not become gelatinous on standing. When these solutions are acidified with hydrochloric acid, only a slight turbidity appears (*rosin, guaiac or other resins*). Resin of Ipomea, dried at 100° C., loses not more than 1 per cent. (*water*). Triturate Resin of Ipomea with distilled water: the latter does not become colored, none of the resin dissolves (*soluble impurities*), and the water does not have a bitter taste (*aloin*). Shake 0.02 Gm. of Resin of Ipomea with 5 cc. of ether, filter, and evaporate the filtrate on filter-paper: no greenish-blue color is produced by the addition of a drop of ferric chloride T.S. to the filter-paper (*guaiac*). Dissolve 0.02 Gm. of Resin of Ipomea in 2 cc. of glacial acetic acid and add a few drops of sulphuric acid: the mixture does not acquire a pink color (*rosin*). Acid number: not less than 25 and not more than 30. Ester number: not less than 170 and not more than 185. Saponification value: not less than 195 and not more than 215." *U. S.*

"Brownish, translucent, brittle fragments, breaking with a resinous fracture; readily reduced to a pale-brown powder. Characteristic, agreeable odor; taste acrid. Readily soluble in *alcohol* (90 per cent.). When 1 gramme of the powdered Resin is triturated with 20 millilitres of *water* and filtered, the filtrate is almost colorless. A solution of 0.1 gramme in 10 millilitres of *solution of sodium hydroxide,* boiled for a few moments and cooled, when acidified with *hydrochloric acid,* may become opalescent but not immediately turbid (absence of certain other resins). Not less than 75 per cent. soluble in *ether.*" *Br.*

The resin of Ipomea is liable to adulteration with rosin, guaiac or jalap resin. These are all excluded by the official tests.

Scoville (*J. I. E. C.,* 1919, xi, 335) has reported on a substance called *Resina drastica* which very closely resembles Ipomea resin. It is less soluble in ether and in chloroform than is true scammony resin or the Mexican scammony resin. It is more slowly soluble in alkalies than is the true or Mexican scammony resin. All three resins gave cloudy solutions in alkaline solution.

L. Lutz (*Pharm. Ztg.,* 1912, xxiii, p. 232) states that the behavior of the resin with iodine when examined microscopically affords a method of distinguishing the resin from a number of its substitutes and adulterants.

For chemistry of this resin see under *Ipomœa.*

Uses.—Ipomea resin is an energetic cathartic, likely to occasion griping, and sometimes operating with harshness. On account of its occasional violence, it is seldom administered, except in combination with other cathartics, the action of which it promotes, while its own harshness is mitigated. Its disposition to gripe may be counteracted by the addition of an aromatic.

Dose, from two to five grains (0.12–0.3 Gm.).

Off. Prep.—Extractum Colocynthidis Compositum, *U. S., Br.;* Pilula Colocynthidis Composita, *Br.;* Pilula Colocynthidis et Hyoscyami, *Br.;* Pilula Scammonii Composita, *Br.;* Pulvis Scammonii Compositus, *Br.;* Tinctura Jalapæ Composita, *N. F.*

RESINA JALAPÆ. U. S. (Br.)

RESIN OF JALAP Res. Jalap.

"Jalap Resin is a mixture of resins obtained from Jalap." *Br.*

Jalapæ Resina, *Br.;* Résine de Jalap, *Fr.;* Jalapenharz, *G.;* Resina di gialappa, *It.;* Resina de jalapa, *Sp.*

"Jalap, in fine powder, 1000 Gm.; Alcohol, Water, each, a sufficient quantity. Moisten the powder with 500 cc. of alcohol, pack it in a cylindrical percolator, and add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding alcohol, until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol until the percolate is reduced in weight to 250 Gm., and add the latter slowly, with constant stirring, to 3000 cc. of water. When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice by decantation with fresh portions of 1000 cc. each of hot water. After having drained off all of the liquid, transfer the Resin to a porcelain dish and heat it to dryness on a water bath." *U. S.*

"Exhaust coarsely powdered Jalap with Alcohol (90 per cent.). Recover most of the alcohol by distillation; pour the concentrated solution thus obtained into eight times its volume of Distilled Water; allow the resin that separates to subside, wash with Distilled Water, and dry at a gentle heat." *Br.*

Extract of Jalap was formerly official. It has been replaced in both the U. S. and British Pharmacopœias by the resin. (See *U. S. D.,* 19th edition, page 479.)

Description and Physical Properties.—"Yellow to brown masses or fragments, breaking with a resinous, glassy fracture and translucent at the edges, or a yellowish-gray to yellowish-brown powder. It has a slight, peculiar odor, a somewhat acrid taste, and is permanent in the air. Resin of Jalap is soluble in alcohol in all proportions; insoluble in carbon disulphide, benzene, and in fixed or volatile oils.

"Add 1 Gm. of the powdered Resin to 20 cc. of chloroform in a stoppered flask, shake the mixture occasionally during one hour, then filter, wash the flask and residue on the filter with three successive 5 cc. portions of chloroform, evaporate the combined filtrates in a tared dish, and dry the residue to constant weight at 100° C.: it weighs not more than 0.3 Gm. Add 1 Gm. of the powdered Resin to 20 cc. of ether in a stoppered flask, shake the mixture occasionally during one hour, then filter, wash the flask and residue on the filter with three successive 5 cc. portions of ether, evaporate the combined filtrates in a tared dish, and dry the residue to constant weight at 100° C.: it weighs not more than 0.12 Gm. (*rosin or other resins*). It is slowly but completely soluble in 5 times its weight of ammonia water, and the solution does not become gelatinous on standing. When this solution is acidified with hydrochloric acid, only a slight turbidity appears (*rosin, guaiac, or other resins*). When Resin of Jalap is dried at 100° C. the loss in weight should not exceed

1 per cent. (*water*). When Resin of Jalap is triturated with distilled water, the latter does not become colored, none of the Resin dissolves (*soluble impurities*), and the water does not have a bitter taste (*aloin*). Shake 0.02 Gm. of Resin of Jalap with 5 cc. of ether, filter, and evaporate the ethereal filtrate on filter paper: no greenish-blue color is produced by the application of a drop of ferric chloride T.S. to the filter paper (*guaiac*). One Gm. of Resin of Jalap when dissolved in 50 cc. of alcohol containing 1 cc. of phenolphthalein T.S., requires not more than 0.5 cc. of half-normal alcoholic potassium hydroxide to produce a red color (*acid resins*). Dissolve 0.02 Gm. of Resin of Jalap in 2 cc. of glacial acetic acid and add a few drops of sulphuric acid: the mixture does not acquire a pink color (*rosin*)." *U. S.*

"In dark-brown opaque fragments, translucent at the edges; brittle, breaking with a resinous fracture; readily reduced to a pale-brown powder. Characteristic odor; taste acrid. Readily soluble in *alcohol* (90 per cent.). When 1 gramme of the powdered Resin is triturated with 20 millilitres of *water* and filtered, the filtrate is almost colorless. A solution of 0.1 gramme in 10 millilitres of *solution of sodium hydroxide,* boiled for a few moments and cooled, when acidified with *hydrochloric acid* may become opalescent but not immediately turbid (absence of certain other resins). Not more than 15 per cent. of the powdered Resin is soluble in *ether* (absence of scammony resin)." *Br.*

The U. S. resin, although pure enough for practical purposes, is still colored. To obtain it colorless, the powdered jalap should be mixed, before percolation, with an equal quantity of finely powdered animal charcoal, and, previously to the introduction of this mixture into the percolator, half the quantity of animal charcoal, similarly powdered, should be packed in the bottom of the percolator. The coloring matter is thus left behind, and the resulting tincture, treated as directed in the process, yields the resin as white as starch.

For further information concerning this resin see under *Jalapa.*

Dose, two to five grains (0.13–0.32 Gm.).

Off. Prep.—Pilulæ Hydrargyri Chloridi Mitis Compositæ, *U. S.;* Pilulæ Catharticæ Vegetabiles, *N. F.*

RESINA PODOPHYLLI. U. S. (Br.)

RESIN OF PODOPHYLLUM Res. Podoph. [Podophyllin]

Podophylli Resina, *Br.;* Podophyllum Resin; Resin of May-Apple; Résine de Podophylle, *Fr.;* Podophyllinum, *P. G.;* **Podophyllumharz,** *G.;* Podofillina, *It.;* Podofilino, *Sp.*

"Podophyllum, in fine powder, 1000 Gm.; Hydrochloric Acid, 10 cc.; Alcohol, Water, each, a sufficient quantity.

"Moisten the drug with 500 cc. of alcohol, pack it in a cylindrical percolator, and add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding alcohol, until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol until the percolate is reduced to the consistence of a thin syrup, and pour this slowly, with constant stirring, into 1000 cc. of water, mixed with the hydrochloric acid and cooled to a temperature below 10° C. When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice by decantation with fresh portions of 1000 cc. of cold water. Spread it in a thin layer upon a strainer and dry the product by exposure to the air, in a cool place, protected from light. Should it coalesce during the drying or aggregate into lumps having a glossy surface, break it into pieces, and powder it in a mortar." *U. S.*

"Podophyllum Rhizome, in No. 40 powder, 1000 *grammes;* Alcohol (90 per cent.), Distilled Water, Hydrochloric Acid, of each, a sufficient quantity. Exhaust the Podophyllum with the Alcohol by percolation; recover the greater part of the alcohol by distillation; pour the resulting liquid into eight times its volume of Distilled Water acidified with one twenty-fourth of its volume of Hydrochloric Acid, constantly stirring; after twenty-four hours collect the deposited resin, wash with Distilled Water, and dry at a temperature not exceeding 40° C." *Br.*

The British Pharmacopœia (1885) abandoned the use of hydrochloric acid, as it is not necessary if the tincture is evaporated to the consistence of *thick* honey. Hydrochloric acid was directed in the 1898 revision as it seems to aid the precipitation when the tincture is not so concentrated. The color and yield of resin of podophyllum may be made to vary by adding alum, acids, or other substances to the water. It darkens if dried with the aid of heat, and its color is indeed no indication whatever of its quality.

The proportion of resin contained in the root of the *P. peltatum* appears to vary very much, the variation possibly depending upon the season of the year at which the drug has been gathered. John Barclay (*P. J.,* 1903, Feb., 164) obtained a percentage of 1.6 to 3.86 per cent., stating that these figures were confirmed by the results of the manufacturers of podophyllin on a large scale, but J. C. Umney states that in five years' experience working with batches of 1000 pounds, the rhizome averaged a yield of 6.6 per cent. Both observers noticed that the Indian rhizome (*P. Emodi*) contains a much larger proportion of resin, the average according to Umney being 11.4 per cent. How far the proportion of podophyllotoxin varies in the different rhizomes does not seem to have been determined. (See B. D. Dott, *P. J.,* 1903, Mar., 460.) (*P. J.,* 1911, lxxxvii, p. 156.)

Lohmann (*Proc. N. J. Pharm. Assoc.,* 1896, 51) states that the fresh drug does not yield as large a percentage of resin as the same drug would if tested after being stored for several years; his experiments led him to the conclusion that in the order of value of resin of podophyllum obtained by various methods, that made by precipitation with water alone came first, that made by the U. S. P. process second, and that made by precipitation with solution of alum last. Dohme and Kelly (*D. C.*, 1903, 251), replying to statements of Lohmann (*Proc. A. Ph. A.*, 1903, 317) regarding the yield of resin from podophyllum, state that: 1, the yield from the method of pouring an alcoholic extract into water was 5 per cent.; 2, from pouring an alcoholic extract into acidulated water 5.5 per cent., and 3, from pouring an alcoholic extract into acidulated water containing 5 per cent. of alum, 4.9 per cent. (See also *Podophyllum.*) The color, by process 1, is grayish-white; 2, light brown; 3, greenish-yellow. The value of resin of podophyllum is accurately estimated by the percentage of podophyllotoxin that it yields. Nearly all of the resin of podophyllum in commerce is made by the alum process, has a deep yellow color and is not wholly soluble in alcohol.

Gordon and Merrell (*Proc. A. Ph. A.*, 1902, p. 343) have proposed a method of valuing resin of podophyllum, based upon the content of picropodophyllin and submit a method of assay.

Description and Physical Properties.—" An amorphous powder, varying in color from light brown to greenish-yellow, turning darker when subjected to a temperature exceeding 25° C. or when exposed to light. It has a slight, peculiar and a faintly bitter taste. *It is very irritating to the eye, and to mucous membranes in general.*

" Resin of Podophyllum is soluble in potassium or sodium hydroxide T.S., forming a deep yellow liquid, which gradually becomes darker on standing, and from which the resin is reprecipitated by acids. A hot aqueous solution of Resin of Podophyllum deposits most of its contents on cooling, and if the cooled liquid is filtered, the filtrate has a bitter taste, and turns brown upon the addition of a few drops of ferric chloride T.S.

" Ash: not more than 1.5 per cent. Resin of Podophyllum is soluble in alcohol with only a slight opalescence and the solution is faintly acid to litmus paper. Add 0.4 Gm. of Resin of Podophyllum to 3 cc. of 60 per cent. alcohol, follow with 0.5 cc. of potassium hydroxide T.S., and shake gently: the mixture does not gelatinize (*difference from resin obtained from Podophyllum Emodi*). Add 1 Gm. of the powdered Resin to 20 cc. of ether in a stoppered flask and shake the mixture occasionally during one hour. Filter, and wash the residue in the flask and on the filter with three successive 5 cc. portions of ether. Evaporate the combined ether solutions in a tared dish and dry the residue to constant weight at 100° C: it weighs not less than 0.75 Gm. Add 1 Gm. of the powdered Resin to 20 cc. of chloroform in a stoppered flask and shake the mixture occasionally during one hour. Filter, and wash the residue in the flask and on the filter with three successive 5 cc. portions of chloroform. Evaporate the combined filtrates in a tared dish and dry the residue to constant weight at 100° C.: it weighs not less than 0.65 Gm.

" Preserve in well-closed containers, protected from light." *U. S.*

" An amorphous powder, varying in color from pale yellow to deep orange-brown. Taste bitter. Entirely or almost entirely soluble in *alcohol* (90 per cent.) and in *solution of ammonia;* precipitated from the former solution by *water,* from the latter by acids. Partly soluble in *ether.* Ash not more than 1 per cent." *Br.*

The official resin is soluble in alkaline solutions, from which it is precipitated by acids, in this respect differing strikingly from the resins of jalap and scammony. It is insoluble in oil of turpentine. For discussion of the solubilities of the fresh resin, see G. M. Beringer (*A. J. P.*, 1894, 11). The name *podophyllin,* given to it by the eclectic practitioners, who have long been in the habit of using this resin, is inappropriate, and should be abandoned.

For description of the chemistry of this resin see under *Podophyllum.*

Uses.—Resin of podophyllum is an active cathartic. It forms the basis of several proprietary " liver pills." It is often used in combination with milder laxatives in chronic *constipation.* It was at one time supposed to be especially cholagogue, but this belief has been of late discredited. A small proportion of extract of belladonna or hyoscyamus mitigates its irritant action. Care must be taken in handling it in quantity, as it is a powerful irritant, frequently producing conjunctivitis.

Dose, one-eighth to one-fourth of a grain (0.008–0.016 Gm.).

Off. Prep.—Tinctura Podophylli, *Br.;* Pilulæ Aloes et Podophylli Compositæ, *N. F.;* Pilulæ Aloes, Hydrargyri et Podophylli, *N. F.;* Pilulæ Aloini Compositæ, *N. F.;* Pilulæ Catharticæ Vegetabiles, *N. F.*

RESINÆ

RESINS

The term " resin " is used in pharmacopœial parlance with a slightly different significance from that generally given to it by chemists. As employed by the latter, the word resin is applied to a group of hard, brittle vegetable products, which are soluble in alcohol and insoluble in water, soften when heated and melt to clear liquids; they are free from nitrogen and are generally supposed to be the products of the oxidation of volatile oils. They are not chemical identities but are mixtures of the following more or less closely related substances: *resinols* which are certain peculiar alcohols or their acid esters; *resino-tannols,* which are brownish alcohol derivatives that give reactions similar to the tannins; organic acids or their anhydrides; *resenes,* which are the oxidation products of terpenes and are neither esters, anhydrides nor acids. In pharmaceutical practice the term resin is applied to a group of preparations made by extracting the drug with either strong alcohol, or acetone, and adding water, the consequent precipitate being the resin. It is evident that this precipitate will contain all the alcohol soluble and water insoluble principles which may be present in the drug including not only the resins proper, but such substances as certain basic principles, substances of a fatty, waxy or caoutchouc-like nature, etc. It is obvious that the resins thus prepared are different substances from the alcoholic extracts, which contain all the ingredients of the medicine which alcohol is able to take from it.

RESORCINOL. U. S. (Br.)

RESORCINOL Resorcin. [Resorcin]

"Resorcinol, when dried to constant weight over sulphuric acid, contains not less than 99.5 per cent of $C_6H_4(OH)_2$ 1:3." *U. S.* "Resorcin, or meta-dihydroxy-benzene, $C_6H_6O_2$, may be obtained by the interaction of fused sodium hydroxide and sodium metabenzenedisulphonate." *Br.*

Resorcinum, *Br.;* Metadioxybenzene, Metadihydroxybenzene; Résorcine, *Fr.;* Resorcinum, *P. G.;* Resorcina, *It., Sp.*

Resorcinol is *metadihydroxybenzene,* while pyrocatechin is the *ortho* compound and hydroquinone the *para* compound. Hlasiwetz and Barth first obtained this organic body in 1864 by fusing galbanum resin with potassium hydroxide; it was subsequently obtained from sagapenum, asafetida, ammoniac, etc. At present it is made commercially by the following process: benzol-disulphonic acid is first made by the action of fuming sulphuric acid upon benzene. To the purified product milk of lime is added, and subsequently sodium carbonate; after the removal of all of the calcium as carbonate the filtrate is evaporated to dryness and fused with sodium hydroxide in an iron crucible. The melted mixture is dissolved in water, acidulated to liberate sulphur dioxide, filtered and extracted with ether or amyl alcohol. The crude resorcinol is purified by distillation and final recrystallization from benzol. It is important that the benzene used in the initial step be free from toluene.

Description and Physical Properties.—"Colorless, or nearly colorless, needle-shaped crystals, or powder. It has a faint, characteristic odor and a sweetish, followed by a bitter, taste. It acquires a pink tint on exposure to light and air. One Gm. of Resorcinol is soluble in 0.9 cc. of water and in 0.9 cc. of alcohol, at 25° C. One Gm. is soluble in about 0.2 cc. of water at 80° C. It is freely soluble in glycerin and in ether, and is slightly soluble in chloroform.

"Resorcinol melts between 109° and 111° C. The addition of 3 drops of ferric chloride T.S. to 10 cc. of an aqueous solution of Resorcinol (1 in 200) produces a bluish-violet color, changing to brownish-yellow on the addition of ammonia T.S. (*difference from catechol and quinol*). Dissolve 0.1 Gm. of Resorcinol in 2 cc. of sodium hydroxide T.S., add a drop of chloroform, and heat the mixture: an intense crimson color is produced, which changes to pale yellow on the addition of a slight excess of hydrochloric acid.

"Its aqueous solution (1 in 20) is neutral or only faintly acid to litmus paper. Ash: not more than 0.05 per cent. An aqueous solution of Resorcinol (1 in 20) does not emit the odor of phenol when gently warmed. Lead acetate T.S. produces no precipitate in an aqueous solution of Resorcinol (1 in 20) (*catechol*).

"Preserve in well-closed containers, protected from light." *U. S.*

"Colorless, shining, acicular or prismatic crystals. Faint odor; taste pungent and sweetish, followed by bitterness. Soluble in less than 1 part of *water,* or of *alcohol* (90 per cent.); very soluble in *ether,* and in *glycerin;* soluble in *olive oil;* slightly soluble in *chloroform.* Melting point 110° to 111° C.; at a higher temperature sublimes without residue and without evolving an odor of phenol. Alkaline solutions darken in color and exhibit a strong greenish fluorescence. A concentrated aqueous solution is colorless (absence of empyreumatic substances), and neutral or only slightly acid to *litmus;* it is unaffected by the addition of *solution of lead acetate* (absence of catechol). A weak aqueous solution is colored bluish-violet by *T. Sol. of ferric chloride,* the color changing to brownish-yellow on the addition of *solution of ammonia* (distinction from catechol and quinol). When 0.5 gramme is mixed with 2 millilitres of *solution of formaldehyde* and 2 millilitres of *solution of sodium hydroxide,* and the mixture heated to boiling, a deep red coloration is gradually developed." *Br.*

Assay.—"Dissolve about 1.5 Gm. of Resorcinol, previously dried to constant weight over sulphuric acid and accurately weighed, in sufficient distilled water to make 500 cc. Transfer 25 cc. of this solution, representing one-twentieth of the weight of Resorcinol taken, to a 500 cc. glass-stoppered flask having a long, narrow neck, add 50 cc. of tenth-normal bromine, dilute with 50 cc. of distilled water, add 5 cc. of hydrochloric acid, and at once stopper the flask. Shake, allow it to stand for one minute, dilute with 20 cc. of distilled water, add 5 cc. of potassium iodide T.S., allow to stand for five minutes, and titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal bromine corresponds to 0.001835 Gm. of $C_6H_4(OH)_2$." *U. S.*

Its official assay is based upon the following reaction:

$$C_6H_4(OH)_2 + 3Br_2 = C_6HBr_3(OH)_2 + 3HBr.$$

The excess of bromine is determined indirectly by titration with sodium thiosulphate V.S.

For method of differentiation of resorcinol from hydroquinone see Wolff, *J. P. C.*, 1917, xv, 94.

Dunlop (*P. J.*, 1909, lxxxii, p. 580) investigated the cause of coloration of resorcin. He found that moisture was the most important factor but that it apparently required light and heat to cause the change after it had once begun.

Uses.—Resorcinol appears in its physiological properties to be allied to phenol. It has marked antibacterial properties, and, according to Martin Cohn (*In. Dis.*, Berlin, 1882), a one per cent. solution of it is sufficient to arrest for a long time putrefactive changes; Cooper (*B. M. J.*, 1912, i, 1235) has shown that it is about one-third as actively germicidal as phenol. When given to the lower animals (Dujardin-Beaumetz, *B. G. T.*, ci, 113) it causes tremors, loss of consciousness, and epileptiform convulsions, which, when the dose has been sufficiently large, become more and more violent and associated with marked disturbances of respiration; this function is finally arrested and death ensues. During the spasms the temperature of the animal is distinctly elevated, but, when there is quiet narcosis, it may fall much below the normal. The urine becomes olive green, deepening into blackish. For two fatal cases of poisoning in children see Boeck, *Dermatol. Wochensch.*, 1915, lx, 449. The largest therapeutic doses produce flushing of the face, with giddiness and buzzing in the ears and some quickening of the breathing and pulse, followed after a time by violent perspiration. Sixty grains caused in man giddiness, violent perspiration with marked anxiety, followed by collapse and unconsciousness. Andeer (*Cb. M. W.*, 1881) took about one hundred and fifty grains of resorcinol dissolved in a pint of water during fifteen minutes. After disturbance of cerebration and of the special senses, he fell into a condition of collapse, with cold extremities, epileptiform convulsions, opisthotonos, loss of consciousness, and marked irregularity of the respiration. Consciousness did not return for five hours.

Resorcinol has been used in medicine as an intestinal antiseptic in *enteritis*, but is probably of no service. In *gastritis* it may exercise some effect but is usually inferior to phenol. Because of its lower toxicity it is frequently employed in gastric lavage or as a wash in *nasal catarrh, chronic colitis, leucorrhea*, and other inflammations of the mucous membranes. Schaffer (*B. K. W.*, 1910, p. 890) highly recommends as a surgical dressing, especially in *furuncles* and *cellulitis*, the use of 50 per cent. of alcohol with 2 or 3 per cent. of resorcinol added. He states that it has a remarkable effect in preventing suppuration. Elze (*Wochenschrift für Ther. and Hyg. des Auges*, 1909, xii, p. 202) asserts that a 1 or 2 per cent. resorcin ointment is useful in *cataract* and will often clear up opaque parts if not too far developed or too deeply located in the lens.

The most important use of resorcin, however, is in the treatment of skin diseases. Many dermatologists attribute it with peculiar alterative properties towards the skin. In dilute solution, 1 or 2 per cent., it is antipruritic as well as antiseptic, and may be used in *acute eczema, urticaria*, and other inflammatory disorders of the epiderm. In stronger solution, 3 to 4 per cent., it is actively stimulating and is employed in the more sluggish conditions as *chronic eczema, seborrhea, psoriasis*, etc. Andeer has used it for its caustic effect in the treatment of *chancres, papilloma*, and *epitheliomata* in the form of a dusting powder.

Dose, three to five grains (0.2–0.32 Gm.).

RHAMNUS CATHARTICA. N. F.

RHAMNUS CATHARTICA Rham. Cathart. [Buckthorn Berries, Baccæ Spinæ Cervinæ]

"Rhamnus Cathartica is the dried, ripe fruit of *Rhamnus Cathartica*, Linné (Fam. *Rhamnaceæ*). Rhamnus Cathartica contains not more than 5 per cent. of unripe fruit or other foreign organic matter." *N. F.*

Rhamni Baccæ, Rhamni Catharticæ Fructus; Baccæ Spinæ Cervinæ; Buckthorn Berries; Hart's Horn Berries; Rhineberry, Waythorn Berries; Baccæ Domesticæ; Kreuzdornbeere, *G.;* Nerprun, Baies de Nerprun, *F.;* Spinamagna, *It.*

Rhamnus cathartica Linn. is a thorny shrub or small tree indigenous to Europe and Western Asia and naturalized in the Eastern United States. It possesses thin, ovate or elliptic leaves with acute or obtuse apex, rounded or cordate base and crenulate-serrate margins. Its flowers are imperfectly diœcious, tetramerous and thickly clustered in the axils of the opposite leaves. Its fruits ripen in September. Each of these is a black, globular drupe about the size of a pea and composed of three or (rarely) four indehiscent cocci, each enclosing a single albuminous seed.

Among other species of Rhamnus which have claimed attention are *R. Wightii* W. & A., a common shrub of Madras and Bombay (*P. J.*, Feb., 1888), and *R. californica* Eschsch. (*R. humboldtiana* Roem. and Schult.), of Mexico, which S. E. Sosa states sometimes produces paralysis in children (*El Estudio*, 1890). (See also *Cascara Sagrada.*)

Description and Physical Properties.—"*Unground Rhamnus Cathartica.*—Flattened, globoid or ovoid, from 4 to 8 mm. in diameter; externally purplish black, wrinkled from shrinking of the mesocarp in drying; three- to four-celled, each cell containing a brown, triangular-convex, seed-like nutlet; in the fully dried, ripe fruit the pedicel is usually lacking. Odor faint, unpleasant; taste at first sweetish, then nauseating and bitter; it colors the saliva purplish red. The unripe fruit, which is to be rejected, is green to greenish brown, firm, furrowed, pedicel usually attached; very bitter; it colors the saliva greenish yellow.

"*Powdered Rhamnus Cathartica.*—Dark brown; numerous fragments composed of epidermal cells and parenchyma some of the latter containing an amorphous substance which appears reddish violet in chloral hydrate T.S., others containing rosettes of calcium oxalate the latter from 0.005 to 0.025 mm. in diameter; fragments of sarcocarp composed of thin-walled cells among which are large secretion cells with a yellowish oily content; stone cells, thick-walled with simple or branching pores from 0.035 to 0.075 mm. in diameter containing a reddish brown amorphous content or prisms of calcium oxalate the latter from 0.005 to 0.025 mm. in length; fibers, long, thick-walled, associated with parenchyma containing prisms of calcium oxalate; fragments of endosperm tissue of cells containing fixed oil and ellipsoidal or nearly spherical aleurone grains.

"When macerated in water the drupe readily assumes its original globular shape, about 1 cm. in diameter. The expressed pulp is colored red by acids and greenish yellow by alkalies. Shake out an aqueous infusion of Rhamnus Cathartica with ether, separate the ethereal solution and shake it with 5 per cent. ammonia water; the ammonia solution assumes a cherry-red color." *N. F.*

The blackish, expressed juice of buckthorn berries was formerly recognized in the Br. Ph. under the name of *Rhamni Succus.* It has the color, odor, and taste of the parenchyma, is reddened by the acids, and from deep green is rendered light green by the alkalies. Upon standing it soon begins to ferment, and becomes red in consequence of the formation of acetic acid. Evaporated to dryness with the addition of lime or an alkali, it forms the color called by painters *sap-green.* The dried fruit of another species, *R. infectoria,* yields a yellow color, and is employed in the arts under the name of *French berries.* The same coloring principles appear to be found in both these species as well as the fruit of the *R. tinctoria.* According to N. Waljaschko and N. Krassowski (*Ph. Ztg.,* 1909, 159), the tinctorial powers are due to glucosides which yield quercetin and rhamnin, $C_{12}H_{12}O_5$.

Tschirch and Polacco (*Ph. Ztg.,* 1909, p. 159) found the fruits to contain about 2 per cent. of emodin-substances and as cleavage products of the glucosides obtained by the action of ferments from the emodin-substances: Emodin, *rhamnoxanthin,* which is isomeric but not identical with frangulin; *rhamnonigrin,* and a resin-like body containing emodin. Other constituents found in buckthorn berries are fixed oil, succinic acid, glucose, galactose, rhamnose, and a pentose, but of the four sugars only glucose was present in the free state, the others being derived from the glucosides. Tschirch and Bromberger (*Schw. Woch. f. Ch. u. Ph.,* 1912, p. 193) report the following constituents: *rhamno-sterin,* $C_{18}H_{28}O_2$; *rhamno-fluorin,* $C_{14}H_{12}O_6$; emodin, iso-emodin, chrysophanol (see under *Rheum*).

Uses.—Buckthorn berries exert an active cathartic effect, but are prone to cause nausea and severe griping. They have been used as hydragogues in *dropsy* and also in the treatment of *rheumatism* and *gout.*

The *dose* of the dried berries is from ten to twenty grains (0.65–1.2 Gm.).

Off. Prep.—Fluidextractum Rhamni Catharticæ, *N. F.;* Syrupus Rhamni Catharticæ, *N. F.*

RHEUM. U. S. (Br.)

RHUBARB

"Rhubarb consists of the dried rhizome and roots of *Rheum officinale* Baillon or of *Rheum palmatum* Linné (Fam. *Polygonaceæ*) or other species of *Rheum* grown in China and Thibet, deprived of periderm tissues. Rhubarb yields not less than 30 per cent. of diluted alcohol-soluble extractive." *U. S.* "Rhubarb is the rhizome of Rheum officinale, *Baill.,* and other species of Rheum, collected in China and Thibet., deprived of most of the cortex, and dried." *Br.*

Rhei Rhizoma, *Br.;* Rhubarb Root; Rhabarbarum; Rhubarbe, *Fr.;* Rhabarber, *G.;* Rhizoma Rhei, *P. G.;* Rabarbaro, *It.;* Ruibarbo, *Sp.;* Hainoung, *Chin.;* Schara-modo, *Thibet.*

The terms *rha* and *rheon*—from the former of which were derived the names *rhabarbarum* and *rhubarb,* and from the latter the botanical title *Rheum*—were applied by the ancients to a root which came from beyond the Bosphorus, and which is supposed, though upon somewhat uncertain grounds, to have been the product of *Rheum rhaponticum* L., growing on the banks of the Caspian Sea and the Volga. This species was also at one time believed to be the source of the medicine now in use; but the true rhubarb has long been known to be wholly distinct from the Rhapontic, and derived from a different source. It was not until the year 1732 that any authentic information was obtained as to its real origin. At that time plants were received from Russia by Jussieu in France, and Rand in England, which were said to be of the species affording the genuine rhubarb, and were named by Linnæus, under this impression, *Rheum rhabarbarum,* a title which has since given way to *Rheum undulatum.* Subsequently, Kaau-Boerhaave obtained from a merchant, who dealt in the rhubarb of Tartary, some seeds which he said were those of the plant producing the root sold by him. These, having been planted, yielded two species of *Rheum, R. undulatum,* and another which Linnæus named *R. palmatum.* Seeds transmitted by Mounsey from St. Petersburg to Hope, and planted in the botanical garden at Edinburgh, produced the latter species, and the same was also raised at Upsala from a root received by Linnæus from De Gorter, and was described in 1767 by the younger Linnæus, two years after the appearance of Hope's paper in the *Philosophical Transactions.* Thus far the evidence appears equally in favor of *R. palmatum* and *R. undulatum.* Colonel Przewalski concluded from personal observation that *R. palmatum* produces rhubarb; but the specimens of the root which he brought to St. Petersburg were stated by Dragendorff to be essentially different from true rhubarb. Claims have also been made from time to time for various other species of *Rheum* as sources of the drug. Pallas, upon exhibiting the leaves of *R. palmatum* to some Bucharian merchants, was told that the leaves of the rhubarb plant were entirely different in shape, and the description he received of them corresponded more closely with those of *R. compactum* than any other known species. Seeds of this plant were, moreover, sent to Miller from St. Petersburg as those of the true Tartarian rhubarb. Wallich, superintendent of the botanical garden at Calcutta, received seeds that were said to be those of the plant which yielded the Chinese rhubarb, growing on the Himalaya Mountains and the highlands of Tartary. These produced a species not previously described, which Wallich named *R. Emodi,* from the native title of the plant. It is the *R. australe* of Don and of Colebrooke, and has been ascertained to afford a root which, though purgative, is very unlike the official rhubarb. Holmstrom (*S. W. P.*, 1921, lix, 183) finds that its chemical constitution differs materially from the official variety. In 1867, French missionaries in Southeastern Thibet forwarded to Soubeiran of Paris, live specimens of a plant which they asserted to yield the true rhubarb, and Baillon subsequently described the flowering plant under the name of *R. officinale.* This species is now established as one of the important sources of the drug of commerce. It is now collected for the greater part, according to Greenish, in the mountains separating Thibet from the Chinese province of Szechuen and extending eastward to Huveh.

The old designations *Turkey Rhubarb* and *East Indian Rhubarb,* still occasionally heard, represent trade names and now indicate nothing more than the routes by which rhubarb was formerly carried into the European market. The official article is now collected entirely in China and Thibet and is most appropriately designated under the trade name of *Chinese Rhubarb.*

Tschirch in discussing the origin of Chinese rhubarb has come to the conclusion that that obtained from Szetschwan, "southern" rhubarb, is derived from *Rheum officinale,* while that obtained from Kukunoor, "northern" rhubarb, is the product of *Rheum palmatum tanguticum* (*A. Pharm.*, 1907, p. 680; and *S. W. P.*, 1910, xlviii, 292).

The genus *Rheum* comprises about twenty-five species of perennial herbs native to Asia. All of the species have large, mostly radical leaves, the blades of which are either entire, toothed and lobed or divided and the petioles thick. The stems arise to the height of 4 to 10 feet. The flowers are small, greenish to greenish-white and occur in panicles of racemes, elevated on scope-like stems which are provided with sheathing stipules (*ochreæ*). Each flower possesses a 6-parted perianth, 6 to 9 stamens and a 3-carpelled pistil with 3 styles which ripens into a triangular winged achene.

There is some difficulty in arranging the species, in consequence of the tendency of the cultivated plants to form hybrids, and it is frequently impossible to ascertain to which of the wild types the several garden varieties are to be referred. Lindley (*Flora Medica*) states that *R. rhaponticum, R. hybridum,* and *R. compactum,* and their hybrids, are the common garden rhubarbs.

R. officinale Baillon is indigenous to the high tablelands of Thibet and Western Asia. It is described in the *Pharmacographia* "as a perennial, noble plant, resembling the common garden rhubarb, but of larger size. It differs from the latter in several particulars: the leaves spring from a distinct crown rising some inches above the surface of the ground; they have a subcylindrical petiole, which, as well as the veins of the under side of the lamina, is covered with a pubescence of short erect hairs. The lamina, the outline of which is orbicular, cordate at base, is shortly 5- to 7-lobed, with the lobes coarsely and irregularly dentate; it attains 4 to 4½ feet in length, and rather more in breadth. The first leaves in spring display before expanding the peculiar metallic red hue of copper."

Rheum palmatum L. is indigenous to Northeastern Asia. Its leaf blades are broad, suborbicular and cordate, 3- to 5-ribbed and deeply palmately-lobed. Its panicle is leafy with pubescent branches, the pedicels of which are seldom longer than the flowers. The var. *tanguticum* of this species resembles the *R. palmatum* but its leaves differ in being more elongated and palmately-cleft. *Rheum palmatum* is known to occur in the province of Kansuh where considerable has been collected.

Besides the species already mentioned, *R. leucorrhizum,* growing in the Kirgheeze Desert in Tartary, *R. capsicum,* from the Altai Mountains, *R. webbianum, R. speciforme,* and *R. moorcraftianum,* natives of the Himalaya Mountains and *R. crassinervium* and *R. hybridum,* cultivated in Europe, but of unknown origin, yield roots which have either been employed as purgatives or possess properties more or less analogous to those of official rhubarb, though they have not entered into general commerce. In Java, the root of an indigenous species is used as a purgative. According to the analysis of J. H. Schmidt, it contains more chrysophan and emodin, and less chrysophanic and rheotannic acids, than does the official drug.

Rhubarb is produced abundantly over a large area of China. It is cultivated extensively in the northern provinces of Shensi, Shansi, Chihli and Honan, the Mongolian province of Tsinghai, in the northwest province of Kansuh and the western province of Szechuen. The rhizome and roots are not considered sufficiently mature for collection until the plant has attained the age of six years. It is dug up twice a year in Tartary, in the spring and autumn; in China not till the winter. After removal from the ground, it is cleaned, deprived of its cortical portion and the smaller branches, and then divided into pieces of a convenient size. Most of the drug is carried to Hankow whence it is shipped to Shanghai to be exported to Europe, and America. Smaller quantities are exported from Canton, Tientsin, Fuhchow and Ning-po. The commercial kinds of rhubarb imported into the United States from China are the " Shensi " and " Canton " varieties. The Shensi variety is considered the best. Both of these varieties occur on the market as *common rounds, flats,* and *high dried rhubarb. Common round rhubarb* represents segments of the dicorticated root and rhizome; *flats* are thick segments of the peeled rhizome split into halves lengthwise and *high dried rhubarb* represents rhubarb which has been first decorticated, then cut into segments which are bored with holes, and strung upon cords to dry either in a heated room or exposed to the sun.

Chinese Rhubarb.—The crude drug occurs in commerce in subcylindrical, conical or barrel-shaped pieces (" rounds "), in plano-convex pieces (" flats "), in cylindrical or barrel-shaped pieces which are perforated (" high dried ") or in square or rectangular pieces (" cut rhubarb "). The outer surface is dusted over with a bright yellow powder and shows evidences of having been peeled and scraped. The outer surface of the *Shensi* variety, when deprived of its yellowish powder, exhibits numerous minute dark reddish-brown lines and dots representing medullary rays imbedded in a whitish parenchyma. This variety is hard, compact and heavy and breaks with an uneven fracture. Its fractured surface varies from bright pink to dull grey and shows, under a hand lens, reddish-brown lines alternating with whitish ones, giving the surface a mottled appearance. It has a characteristic odor and a bitter, astringent taste. When chewed it is gritty between the teeth (due to abundant rosette crystals of calcium oxalate) and tinges the saliva yellow.

Canton Rhubarb differs from the *Shensi* variety in being lighter in weight and in color, less compact and more fibrous in texture, and in exhibiting a nearly uniformly granular instead of a marbled appearance, when fractured. With the pieces of good quality others often come mingled, defective from decay or improper preparation. These are usually lighter, and of a dark or russet color. Like all the other varieties of rhubarb, this is liable to be attacked by insects, and in almost every large parcel pieces may be found which have suffered from this cause. Occasionally pieces of the drug have been observed to possess dark-colored or hollow central areas. This is due to the decay of these portions during the preparation of the drug. Such specimens are known as " Black Hearted Rhubarb."

Chinese rhubarb is the only kind recognized by the U. S. or Br.

Description and Physical Properties.—" *Unground Rhubarb.*—In subcylindrical or flattened pieces, frequently showing a large perforation; from 5 to 17 cm. in length and from 4 to 10 cm. in diameter; outer surface yellowish-brown with lighter colored striations and occasional small patches of brown cork; more or less covered with yellowish-brown powder; hard; fracture uneven, showing stellate vascular bundles and a granular, yellowish or pinkish-brown mottled surface; odor aromatic, agreeable; taste bitter and astringent.

" *Structure.*—Occasional patches of thin-walled cork cells; medullary rays wavy, 2 to 4 cells in width, cells often with reddish-brown contents; vascular bundles with internal sieve and cambium; parenchyma cells containing either starch or large aggregate crystals of calcium oxalate.

" *Powdered Rhubarb.*—Yellowish-brown to reddish-brown; rosette aggregates of calcium oxalate up to 0.15 mm. in diameter; starch grains from 0.004 to 0.025 mm. in diameter, spheroidal, single and 2- to 3-compound, with central cleft hilum; tracheæ few, reticulate and spiral.

" Powdered Rhubarb becomes red upon the addition of alkalies. Boil 0.1 Gm. of powdered Rhubarb with 10 cc. of an aqueous solution of potassium hydroxide (1 in 100); allow it to cool, filter, acidulate the filtrate with hydrochloric acid and shake it with 10 cc. of ether: the ethereal layer is colored yellow on standing. Shake this ethereal solution with 5 cc. of ammonia T.S.: the latter is colored cherry-red (presence of *emodin*) and the ethereal layer remains yellow (presence of *chrysophanic acid*).

" Boil 10 Gm. of powdered Rhubarb for fifteen minutes with 50 cc. of diluted alcohol under a reflux condenser, filter, and concentrate to 10 cc. Cool, shake with 15 cc. of ether, and set aside for twenty-four hours: yellowish, prismatic crystals should not form (*rhapontic rhubarb*).

" **Assay.**—Proceed as under anhydrous diluted alcohol-soluble extractive, page 1552." *U.S.*

" In compact, firm, cylindrical, barrel-shaped, conical or plano-convex pieces, often perforated, the perforation sometimes containing a fragment of cord. Surface rounded or slightly angular, but not shrunken, marked with reddish-brown lines embedded in a whitish ground-substance;

usually covered with a bright brownish-yellow powder. Fracture granular and uneven, the pinkish-brown fractured surface exhibiting numerous reddish-brown points and lines on a white ground-substance. For a short distance within the cambium the structure is radiate; within this there is a more or less distinct ring of closely approximated vascular bundles with central bast and radiating, reddish-brown medullary rays; in the parenchymatous cells abundant starch grains, an amorphous yellow substance and very large cluster-crystals of calcium oxalate. In powdered Rhubarb large cluster-crystals of calcium oxalate, often more than 100 microns in diameter, simple or compound starch grains, the single grains seldom exceeding 20 microns in diameter, fragments of reticulated vessels and of parenchymatous tissue, and small yellowish masses and globules which assume a reddish-pink color with *solution of ammonia;* it is free from added starch and from sclerenchymatous cells and fibres. Characteristic, somewhat aromatic odor; taste bitter, slightly astringent. Ash not more than 15 per cent." *Br.*

European or English Rhubarb.—In various parts of Europe, especially in England, the *R. rhaponticum* and *R. officinale* are cultivated and are imported occasionally into the United States. The rhizomes are usually offered separately from the roots. English rhubarb (from *Rheum rhaponticum*) is lighter than the Asiatic, more spongy, and often somewhat pasty under the pestle. It is redder, and when broken exhibits a more compact and regular marbling, the pinkish lines being arranged like rays from the center towards the circumference. The "starlike spots" are either wanting or very few and scattered. The powder also has a brighter yellow tint. The odor is feeble and less aromatic than that of the Asiatic varieties; the taste is astringent and mucilaginous, with little bitterness, and the root, when chewed, scarcely feels gritty between the teeth, and but slightly colors the saliva. Few crystals of calcium oxalate are discoverable by means of the microscope. Much English rhubarb is obtained from *R. officinale,* and is put on the market in flat, concave, and convex pieces weighing from three to four ounces each. Externally the convex surface has deep longitudinal furrows and a longitudinal ramification of conspicuous veins, giving rise to an appearance of net-vein markings. In the center of the concave surface is a small hole similar to that formerly seen in Russian rhubarb. On the inner surface the stellate markings resemble very closely those found in Chinese rhubarb. The fracture of this form shows a parallel arrangement of whitish and reddish lines, representing parenchyma and medullary rays. When rapidly grown in rich soil, English rhubarb is lighter, more spongy, and less active than when slowly grown without high cultivation.

Rhapontic rhubarb is still found to some extent in European markets and occasionally has been detected in supplies offered for entry here. Tschirch has proposed a ready method for detecting the admixture. It depends on the insolubility in ether of the crystalline glucoside, rhaponticin or ponticin. This is not an anthraquinone derivative. (*A. Pharm.,* 1905, p. 443; and *S. W. P.,* xliii, p. 253.) Hesse has also made an elaborate study on the chemistry of rhapontic root grown in Austria. (*J. f. prakt. Chem.,* 1908, lxxvii, p. 320.)

The *rhapontic root* differs in transverse section from true rhubarb by its distinctly radiated structure, and by its stellate spots (compound bundles) being fewer, and more isolated and diffused.

Choice of Rhubarb.—In selecting good rhubarb, without reference to the commercial variety, those pieces should be preferred which are moderately heavy and compact, of a bright color, brittle, presenting when broken a fresh appearance, with reddish and yellowish veins intermingled with white, of an odor decidedly aromatic, of a bitter and astringent not mucilaginous taste, feeling gritty and staining the saliva yellow when chewed, and affording a powder either bright yellow, or yellow with but a slight reddish-brown tinge. When very light, rhubarb is usually partially decayed or worm-eaten; when very heavy and compact, it is of inferior species, culture, or preparation. Partially decayed, worm-eaten, or otherwise inferior rhubarb is often powdered, and colored yellow with turmeric. The shavings left when Chinese rhubarb is trimmed are used for powdering. The stellate markings observed in the cut or broken surface of the Chinese rhubarb has been believed by various pharmacologists to be of great practical value in determining the true character of the rhizome and especially in enabling a distinction between the Chinese and European rhubarb to be made. There has been a general concurrence with the statements of Tschirch that the star spots are never present in the root, occurring only in the rhizome. In an elaborate re-examination of this subject by Jakabhasy, however, the star spots were found in the root as well as in the root stock and also in the European as well as in the Asiatic rhubarb. Nevertheless, Jakabhasy states that it is possible to distinguish the two rhubarbs by the fact that in the European rhubarb the star spots occur in greater number on the longitudinal section while in the Chinese rhubarb they are present on the transverse section, where they form a circle. He believes also that the superabundance of starch and the lack of crystals in the star spots are diagnostic of the European drug. When the rhubarb is powdered these characteristics are not available, under which circumstances the percentage of ash seems to be valuable. The Chinese rhubarb, unless of very inferior quality, yields from 8 to 25 per cent.; the European 1.3 to 6 per cent. of ash. According to Jakabhasy, Shensi is the best, Shanghai the poorest, and Canton the intermediate variety of Chinese rhubarb. Of the European the English is the most, the French next, and the Austrian the least active.

Tschirch and Puzzkowski have reported that the rhubarb from the Altai Mountains meets all of the requirements for official rhubarb, *C. V. C. P. Al. J.*, 1916, xxiii, 12.

Constituents.—Rhubarb has been the subject of extensive and intensive chemical investigations, of which the most important in recent years have been those of Hesse (*Proc. A. Ph. A.*, 1896, p. 549), Tschirch and Heuberger (*A. Pharm.*, 1902, cciv, 596, and *Ph. Ztg.*, August 3, 1904, 651), Eyken (*Ph. Wb.*, 1904, xli, 177), and Tutin and Clewer (*Tr. Chem. Soc.*, 1911, xcix, 946). The result of these investigations may be briefly summed up as follows: There is present in rhubarb, besides various unimportant vegetable substances, a small amount of a volatile oil with a strong characteristic odor of rhubarb, and about 2 per cent. of gallic acid and smaller quantities of tannic acid. Its most important constituents, however, are certain derivatives of methylanthracene. In order to clear up some of the confusion which has arisen from reduplication of names, it will be necessary to briefly review the chemistry of this group of principles.

Anthraquinone Derivatives.—A number of the vegetable laxatives contain principles allied to methyl-anthraquinone—or glucosides which yield such substances on hydrolysis—to which it is generally believed they owe their cathartic powers. The names which have been applied to these are so numerous that it has given rise to much confusion. While our present state of knowledge does not permit of too dogmatic statements it has seemed worth while to briefly explain the probable relationship of these various compounds.

Chrysophanic acid—more properly *Chrysophanol,* as it is not an acid—is a dihydroxy-methyl-anthraquinone, $C_{14}H_5O_2(OH)_2CH_3$. It is found in rhubarb to the extent of 0.5 per cent., in aloes, cascara and other species of Rhamnus. *Emodin* (*Frangula-emodin, Rheum-emodin*) is a trihydroxy-methyl-anthraquinone, $C_{14}H_4O_2(OH)_3CH_3$. It exists—either free or combined with a sugar as a glucoside—in aloes, rhubarb, Rhamnus species, Rumex, etc. *Frangulin, avornic acid,* and *rhamnoxanthin* seem to be glucosides yielding emodin. *Aloe-emodin,* also called *iso-emodin,* is isomeric with emodin, its formula probably being $C_{14}H_5O_2(OH)_2CH_2OH$. *Rhabarberon,* of Hesse, found in rhubarb was probably an impure aloe-emodin. It occurs in aloes, and to the extent of about 0.2 per cent. in rhubarb. *Emodin monomethyl ether* has been found by Tutin and Clewer in rhubarb. Its formula is $C_{14}H_4O_2(OH)_2CH_3OCH_3$. *Rhein* is an acid found in rhubarb, which can be regarded as the acid of chrysophanol as it has the formula $C_{14}H_5O_2(OH)_2COOH$.

Rhubarb contains emodin, emodin monomethyl ether and rhein, which, however, according to Tutin and Clewer, are devoid of purgative powers, also aloe-emodin, chrysophanol and glucosides of these. According to Tutin and Clewer, however, the chief cathartic principle is a non-glucosidal resin which yielded on hydrolysis various anthraquinone compounds and which is present to the extent of about 10 per cent.

B. H. St. John of the laboratory of the A. M. A. has called attention to the fact that *Acer spicatum* gives reactions similar to the emodin test applied to rhubarb and other cathartic drugs. (*A. J. P.*, 1917, lxxxix, 10.)

There are other interesting principles in rhubarb. The calcium oxalate is interesting from its quantity, and from the circumstance that, existing in distinct crystals, it occasions the grittiness of the rhubarb between the teeth. The proportion seems to vary exceedingly in different specimens. According to Scheele and Henry, it constitutes nearly one-third, and Queckett found between 35 and 40 per cent., while Brandes obtained only 11, Schrader only 4.5 parts in the hundred, and Dragendorff, in five examples analyzed, from 1.2 to 5.6 per cent. Little or no difference of composition has been found between the Russian and the Chinese rhubarb. The European contains but a small proportion of calcium oxalate, and is therefore less gritty when chewed. It has, however, more tannin and starch than the Asiatic.

When powdered rhubarb is heated, odorous yellow fumes rise, which are probably in part the vapor of chrysophanic acid. Its infusion is reddened by the alkalies, in consequence of their union with this acid, and their reaction on the other coloring principles. It yields precipitates with gelatin, most of the acids, ferric salts, lead acetate, mercurous nitrate, silver nitrate, stannous chloride, lime water, and solutions of quinine. Nitric acid occasions at first a turbidity, and afterwards the deposition of a yellow precipitate. The substances producing precipitates may be considered as incompatible with the infusion.

For a method of detecting the presence of turmeric in powdered rhubarb by the influence of chloroform on the coloring principles of each of these substances, and of distinguishing through the same agency between the true Chinese rhubarb and that of European origin, see *P. J.*, 1898, 126, and *Chem. Abst.*, 1918, xii, 1337.

Uses.—Rhubarb differs from the other laxatives of the anthraquinone group—such as aloes, cascara, etc.—in that it has a larger percentage of tannic acid. On account of the considerable quantity of tannin its purgative action is often followed by constipation. This sequence of effects has led to its use in the treatment of *diarrheas,* especially of the inflammatory type, on the theory that the catharsis it caused would evacuate the irritant *materies morbi,* and that its subsequent astringency would check the excessive secretion. The logic is plausible, but erroneous. As the action of its cathartic principles is limited to the lower bowel it has very little influence in cleaning out the smaller bowel which is frequently involved in acute *diarrheas.* In inflammations of the colon, such as *dysentery,* its use might appear more reasonable, but even here it is greatly inferior to less irritant laxatives because it acts chiefly by virtue of its local irritant influence. Rhubarb is also widely prescribed in atonic *dyspepsia* attended with *constipation.* It is frequently combined with an alkali, either magnesia or soda.

It sometimes occasions griping. Its coloring principles is absorbed, and may be detected in the urine. By its long-continued use the perspiration, especially that of the axilla, is said to become yellow, and the milk of nurses cathartic. It gives a yellow color to the alvine discharges.

By the roasting of rhubarb its cathartic property is diminished, probably by the volatilization of the purgative principle, while its astringency remains unaffected. When so treated it is termed *torrefied rhubarb.* This mode of treatment has been sometimes resorted to in cases of *diarrhea.* By long boiling the same effect is said to be produced.

Few medicines are used in a greater variety of forms. It is most effectual in substance either as a pill or powder. It is frequently given in the shape of pill, combined with an equal proportion of soap when its laxative effect is desired. The infusion is much used in cases of delicate stomach, and is peculiarly adapted. The syrup, tincture, and fluidextract are also useful preparations; but the most popular forms are those in which it is combined with an antacid as in mixture of rhubarb and soda or the compound powder of rhubarb and magnesia.

Rhubarb Poisoning.—The stalks of certain species of rhubarb (sometimes called *pie-plant*) are widely used as a food-stuff. Several cases of severe, and even fatal, poisoning have been reported from them. While the acid taste of the stalks is in part due to malic acid it is well established that they contain also considerable quantities of oxalic acid, which is probably the toxic ingredient. The amount of oxalic acid is usually larger in the leaves than in the stems and the former are correspondingly more dangerous. Von Itallie and Lemkes (*Ph. Wb.,* 1917, v, 1234) found the oxalic acid, extractable with 5 per cent. of hydrochloric acid, in the stems of various species to range from 0.4 to 1.0 per cent., and in the leaves from 0.3 to 1.1 per cent. For report of cases of this poisoning, see *J. A. M. A.,* 1919, lxxiii, 926.

Dose, as a purgative, from twenty to thirty grains (1.3–2.0 Gm.); as a laxative and stomachic from five to ten grains (0.32–0.65 Gm.).

RHŒADOS PETALA. Br.

RED POPPY PETALS

"Red-Poppy Petals are the fresh petals of Papaver Rhœas, *Linn.*" *Br.*

Corn Poppy, Corn Rose; Flores Rhœados; Poppy Flowers; Flos Papaveris; Coquelicot, Pavot rouge, *Fr.;* Wilder Mohn, Klapperrose, Llatschrosen, *G.;* Rosolaccio, *It.;* Amapola (Flor de), *Sp.*

The *red* or *corn poppy, Papaver Rhœas,* is distinguished by its hairy stem, which is branched, and rises about a foot in height, by its incised pinnatifid leaves, by its urn-shaped capsule, and by the full, bright, scarlet color of its petals. It is a native of Europe, where it grows wild in great abundance, adorning especially the fields of grain with its brilliant flower and often proving a troublesome weed to the farmer. It has been naturalized in this country.

Its capsules contain the same kind of milky juice as that found in *P. somniferum,* and an extract has been prepared from them having the properties of opium; but the quantity is too small to repay the trouble of its preparation. Filhol has shown that the extract contains morphine, but in a proportion exceedingly minute compared with that in which it exists in opium. The petals are the official portion. They have a characteristic odor, and a mucilaginous, slightly bitter taste. By drying, they lose their odor, and assume a violet-red color.

"Transversely elliptical, about five centimetres wide, bright scarlet, smooth and lustrous; margin entire. Characteristic, somewhat unpleasant odor; taste slightly bitter." *Br.*

Chevallier believed that he had detected a very minute proportion of morphine in an extract obtained from them; but Attfield seems to have determined satisfactorily the non-existence of morphine in the petals, having sought this alkaloid by three different processes, using a pound of the petals in each experiment, and failed to detect the least evidence of its presence. (*P. J.,* 1873.) Hesse, in 1867, found the alkaloid, *rhœadine* $C_{21}H_{21}O_6N$, in the expressed juice of the fresh petals but not in the dried drug. (See *A. J. P.,* 1890, p. 179). According to the same author there is also present a small amount of meconic acid.

Rhœadine is crystallizable, faintly alkaline to litmus, but does not readily form salts with the acids. It is sparingly soluble in water. It melts at 232° C. It is sparingly soluble in ether, alcohol, benzene, chloroform, water, and ammonia. Its solutions in dilute acids acquire an intense purple color on addition of strong hydrochloric or sulphuric acid, due to the formation of a coloring matter. This color is destroyed by alkalies and restored by acids, and is so intense that 1 part of rhœadine will color 10,000 parts of water purple-red, 200,000 deep rose-red, and 800,000 distinctly red, although only a portion of the base is converted into coloring matter. The solution then filtered through bone-black shows the presence of a base, *rhœagenine,* isomeric with rhœadine, but strongly basic. Rhœadine is found also in opium.

The physiological power of poppy petals on the system is exceedingly feeble, and they are valued more for their beautiful scarlet color, which they communicate to water, than for their medicinal virtues. The alkaloid rhœadine appears to be non-toxic. According to Leo Meier, the coloring principles of the flowers are two acids, which he denominates *rhœadic* and *papaveric acids.* (See *A. J. P.,* xviii, 211.) A syrup is prepared from them, which was formerly prescribed as an anodyne in catarrhal affections, but is now little esteemed except for its color.

Off. Prep.—Syrupus Rhœados, *Br.*

RHUS GLABRA. U. S.

RHUS GLABRA Rhus. Glab. [Sumac Berries]

"Rhus Glabra is the dried, ripe fruit of *Rhus glabra* Linné (Fam. *Anacardiaceæ*). Rhus Glabra contains not more than 5 per cent. of stems or other foreign organic matter." *U. S.*

Rhus Glabrum, *U. S.,* 1870; Sleek or Scarlet or White, Sumach; Shoe-make; Vinegar Tree; Sumac, *Fr.;* Sumach, *G.*

Rhus glabra called variously *smooth sumach, Pennsylvania sumach,* and *upland sumach,* is an indigenous shrub from four to twelve feet or more in height. The leaves are pinnately compound with smooth petioles, and blades consisting of numerous opposite leaflets, with an odd one at the extremity, all of which are lanceolate, acuminate, acutely serrate, glabrous, green on their upper surface, and whitish beneath. In the autumn their color changes to a beautiful red. The flowers are greenish red, and disposed in large, erect, terminal compound thyrses. The fruit is in clusters of small crimson drupes.

The shrub is found in Canada and almost all parts of the United States, growing in old neglected fields, along fences, and on the borders of woods. The flowers appear in July, and the fruit ripens in the early part of autumn. The bark and leaves are astringent, and are largely used, especially the leaves, in tanning leather and in dyeing. The sumach for the manufacture of extract for tanners' use is largely cultivated in Virginia, where the annual crop reaches from 7000 to 8000 tons, and is collected at any time between the first of July and the appearance of frost.

The drupes have a sour, astringent, not unpleasant taste, and are often eaten by the country people with impunity.

The fruits of *Rhus glabra* have been replaced by those of the *Stag Horn Sumac* (*Rhus typhina* L.) This shrub is very abundant in the Eastern United States. The fruits resemble those of *Rhus glabra* both in form and size but are distinguished by being covered with needle-like crimson hairs which are frequently over 2 mm. long. For detailed description of the fruits of these two plants see Kraemer. (*A. J. P.,* 1913, p. 398.)

Description and Physical Properties.—"*Unground Rhus Glabra.*—Flattened ovoid, nearly globular or somewhat reniform; from 3.5 to 5.5 mm. in length, nearly as broad, but usually somewhat less in thickness; a raised scar at the apex and the five-parted calyx occasionally with a short pedicel at the base; externally dark red, velvety with short hairs; endocarp smooth, shiny, crimson to yellowish-red; 1-locular, 1-seeded; seed brown, very hard; inodorous; taste acidulous and astringent.

"*Powdered Rhus Glabra.*—Brownish-red; non-glandular hairs numerous, elliptical, ovoid or spatulate, from 0.125 to 0.300 mm. in length and from 0.045 to 0.080 mm. in width, usually several-celled, uniseriate, the cells filled with pink or red dried sap in which occasionally occur rod-shaped crystals; also a few, slender, one-celled, colorless, non-glandular hairs; glandular hairs numerous, brownish or brownish-red with short, 1-celled stalks and multicellular heads, from 0.045 to 0.085 mm. in length; fragments of red-celled epicarp with adhering mesocarp having spiral tracheæ; stone cells of endocarp very small and with irregularly thickened walls; fragments of embryo with small angular cells containing aleurone and fixed oil." *U. S.*

For a paper on the relative proportion of the constituents found in the husk and seed portion of the fruit by Frankforter and Martin, see *A. J. P.,* 1904, 151.

Sumac berries contain malic acid as well as calcium malate, a small quantity of volatile oil, coloring matter, etc., but their therapeutic properties are due to the presence of a tannin, which is probably the same as gallo-tannic acid (see Peacock, *A. J. P.,* 1925, xcvii, 463). Gallic acid, according to Peacock, never occurs naturally but small amounts may be present, resulting from decomposition of the tannin. Much larger proportions of tannin are found in other parts of the plant, the leaves, for example, yielding from 16 to 25 per cent. and Trimble (*A. J. P.,* 1890, p. 564) collected some galls from the leaves that yielded from 61 to 71 per cent. An extract prepared from the sumac has been used in tanning leather.

Uses.—Sumac berries are used in medicine solely for their astringent effect. Because of their not unpleasant flavor they afford an excellent astringent gargle in various forms of *sore throat.* For this purpose the fluidextract may be diluted with from 1 to 3 parts of rose water. Internally the fluidextract is employed in *diarrhea.*

The *dose* of the fluidextract is fifteen to thirty minims (1–2 cc.).

Off. Prep.—Fluidextractum Rhois Glabræ, *U. S.*

ROSA. U. S. (Br.)

ROSE [Rosa Gallica U. S. P. IX]

"Rose is the dried petals of *Rosa gallica* Linné (Fam. *Rosaceæ*), collected just before the expansion of the flowers." *U. S.* "Red Rose petals are the fresh or dried unexpanded petals of Rosa gallica, *Linn.;* obtained from cultivated plants." *Br.*

Rosæ Gallicæ Petala, *Br.;* Red-Rose Petals; Flores Rosarum Rubrarum; Rose rouge, Rose de Provins, *Fr.;* Sammtrose, Zuckerrose, Französische Rose, Essigrosenblatter, *G.;* Rosa rossa, *It.;* Rosa roja (Flor de), *Sp.*

As one time pale rose or *Rosa centifolia* was official in addition to red rose or *Rosa gallica.* There is no uniformity on the subject in the several Pharmacopœias. The Pharmacopœia of the Netherlands and the French Codex still include both species. The German Pharmacopœia, on the other hand, specifies only the petals of *Rosa centifolia.* The British and Austrian Pharmacopœias are in unison with the U. S. Pharmacopœia in restricting the drug to *R. gallica.*

Rosa gallica is a shrub smaller than *R. centifolia* L., but resembling it in the character of its foliage. The stem is beset with short bristly prickles. The flowers are very large, with obcordate widely spreading petals, which are of a rich crimson color, and less numerous than in the *R. centifolia.* The stamens on thread-like filaments, and the villose styles bearing papillary stigmas, are numerous. The fruit is an oval, shining, orange red hip. The red rose is a native of the south of Europe, and is cultivated in gardens throughout the United States. The commercial supplies are obtained from France and Austria.

Description and Physical Properties.—"*Unground Red Rose.*—Petals either separate or imbricated in small cones, broadly ovate, summit rounded and deeply notched, margin entire and somewhat recurved, base obtuse; externally of a purplish-red color except the light brown claw; texture velvety; when dry brittle; odor agreeable; taste astringent and slightly bitter.

"Usually in little cone-like masses, or sometimes separate and more or less crumpled. Petals velvety, deep purplish-red passing into brownish-yellow towards the base. Fragrant odor; taste slightly astringent." *Br.*

The petals should be gathered before the flower has blown, separated from their claws, dried in a warm sun or by the fire, and kept in a dry place. Their odor, which is less fragrant than that of *R. centifolia,* is improved by drying. They have a velvety appearance, a purplish-red color, and a pleasantly astringent and bitterish taste.

An illustrated article, on the structural characteristics of rose petals, whole and powdered, has been published by Hans Kramer in *B. P. G.,* 1907, xvii, p. 354.

Various astringent principles have been suggested as occurring in rose petals. According to Peacock (*Proc. Penna. Pharm. Assn.,* 1920, xlv, 162), they contain no gallic nor gallotannic acids, their astringency is due chiefly to a new tannin for which the name of *rosatannic acid* is suggested. They also contain small amounts of quercitrin.

Their coloring matter is due to the decomposition of a glucoside, *anthocyanin,* a sap pigment which is found in many flowers, and other plant tissues.

The *anthocyanins* are glucosides of three parent bodies named *pelargonidin, cyanidin* and *delphinidin.* The *anthocyanins* are red in acid solution, violet in neutral and reddish brown to purple or blue in acid solution.

In the production of the color the glucosides are hydrolyzed by ferments of the emulsin type, the free chromogen is oxidized by atmospheric oxygen activated by oxydases. The chromogen in rose petals is *cyanin* which forms a chloride of the composition, $C_{27}H_{31}O_{16}Cl$. This hydrolyzes to form cyanidin, $C_{15}H_{11}O_6$ and glucose by the action of acids. Some rose petals contain as much as 10 per cent. of *cyanin.* Their infusion is of a pale reddish color, becoming bright red on the addition of sulphuric acid. As their color is impaired by exposure to light and air, they should be kept in opaque well-closed bottles or canisters.

Uses.—Red rose is at present chiefly employed as an elegant vehicle.

Off. Prep.—Confectio Rosæ Gallicæ, *Br.;* Fluidextractum Rosæ, *U. S.;* Infusum Rosæ Acidum, *Br.* (*N. F.*); Confectio Rosæ, *N. F.;* Syrupus Rosæ (from Fluidextract), *N. F., Br.*

RUBI IDÆI FRUCTUS. N. F.

RASPBERRY Rub. Id. Fruct.

"Raspberry is the fresh, ripe fruit of varieties of *Rubus Idaeus* Linné or of *Rubus Strigosus* Michaux (Fam. *Rosaceæ*)." *N. F.*

Framboise, *Fr.;* Himbeere, *G.;* Lampone, Mora di Rovo, *It.*

The genus *Rubus* is divided into a number of sections. The section *Idæobatus,* or raspberries, are shrubs with compound leaves having an edible fruit composed of pulpy one-seeded coherent little drupes which separate from the dry receptacle. In the blackberries, the receptacle is juicy and coheres with the fruit.

Of the official raspberries, the native species, R. *strigosus,* is a shrubby biennial about three to six feet in height, found in rocky hillsides throughout the North American Continent east of the Rocky Mountains. Its stems are shrubby and densely beset with weak glandular bristles. The European species, *R. Idaeus,* is taller and more erect and has a somewhat larger fruit It is widely cultivated in the United States and is the ordinary garden raspberry. The native purple wild raspberry, *R. neglectus* Peck, whose fruit is purple—or yellowish in cultivation—is also occasionally a commercial article.

Description and Physical Properties.—"An aggregate fruit, globular or hemispherical with a concave depression at the base where separated from the receptacle, composed of twenty or more small, rounded-polygonal, succulent drupelets; pericarps externally red, non-globular hairs numerous up to 0.640 mm. in length; mesocarps fleshy, juice red; parenchyma with rosettes of calcium oxalate up to 0.035 mm. in diameter; endocarps small stones with wrinkled surfaces. Odor characteristic, aromatic; taste pleasant, sweet, acidulous. For pharmaceutical purposes, Black Raspberries, the fresh ripe fruit of varieties of *Rubus occidentalis* Linné (Fam. *Rosaceæ*) may be substituted either in part or wholly for Red Raspberries." *N. F.*

The acids in raspberry juice have been found by Broeksmit to consist of citric acid with a small amount of acetic acid. No tartaric, malic or malonic acid is present (*Ph. Wb.*, 1918, lv, 1410).

The *Rubus occidentalis* L., *black raspberry* or *thimbleberry* of the Northern United States, which is also cultivated, is sometimes employed for the making of a raspberry syrup, but yields a very inferior product.

Rubus Chamœmorus L. (*Cloud Berry, Baked-Apple Berry*) inhabits the northern portions of both continents and is largely employed in northern Russia, in the form of an infusion of the berries or leaves, as a diuretic in *dropsy.* The fruits are about 2 cm. in diameter, of an amber color, and very juicy when ripe. Popoff found in it a crystallizable acid which is an essential diuretic, acting directly upon the renal secreting structures without affecting either cardiac action or arterial tension. (*Vrach.*, iv, 1886.)

Raspberries are used only for their flavor.

Off. Prep.—Syrupus Rubi Idæi, *N. F.*

RUBUS. N. F.

RUBUS [Blackberry Bark]

"Rubus consists of the dried bark of the rhizome and roots of the section *Eubatus* Focke of the genus *Rubus* Linné. Rubus contains not more than 10 per cent. of adhering wood and not more than 2 per cent. of other foreign organic matter." *N. F.*

Blackberry Bark; Bramble; Finger Berry; Ecorce de Ronce Noir, *Fr.;* Brambeeren, Brombeerrinde, *G.*

The N. F. IV recognized only, as the source of blackberry root, three species *Rubus villosus* Ait., *R. cuneifolius* Pursh. and *R. nigrobaccus* Bailey; the last named is not recognized by most botanists being considered identical with the *R. vollosus.* This group of plants is difficult to divide into species because of the occurrence of a great number of intermediate forms. The present edition of the N. F. has not attempted to differentiate between them and has admitted the whole section *Eubatus* of the genus *Rubus.* This section would include a very large number of plants most of which, however, do not grow in this country and probably never appear in American drug markets. The species which are of most importance as sources of the drug are described below.

Formerly the N. F. recognized both the root and the fruit, but only the first named is at present official.

Rubus villosus Ait. is the common blackberry of North America and is widespread in burned-over woodlands and along roadsides from New England to Florida. It is a shrub attaining a height of 4 to 6 feet and further characterized by possessing imparipinnate leaves with 3 to 5 ovate leaflets with serrate margin and hairy on the ribs of the lower surface. Its young, green branches and pedicels bear numerous glandular hairs while its older branches are straight-prickly, purplish and reclining.

The *R. Alleghaniensis* Porter, which is found in the mountainous portions of New England is generally regarded as a variety of this species. It differs from the type in having narrower leaflets and a longer, less succulent, fruit.

Rubus canadensis L. (*R. procumbens* Muhl.) is an upright or ascending shrub growing in sandy soil of many sections of the United States east of the Mississippi river. It attains a height of about 4 feet and differs from the preceding species chiefly by possessing recurved prickles and wedge-ovate leaflets which are serrate above middle and white-tomentose on lower surface.

Rubus villosus Ait. (*R. procumbens* Muhl.) or *dewberry* differs from the foregoing species in being low-growing or prostrate in habit. Its stems bear stout recurved prickles and its leaflets are rhombic-obovate with doubly serrate margins. It is a native of open fields of the northern United States, extending from Maine to Virginia and west to Kansas. The commercial supplies of the drug are obtained chiefly from North Carolina, Virginia, Michigan and Illinois.

Description and Physical Properties.—"*Unground Rubus.*—In elongated, tough, flexible quills or bands, from 3 to 6 mm. in diameter, the bark from 1 to 2 mm. in thickness; outer surface deep red-brown or dark gray-brown, occasionally blackish brown, somewhat scaly; inner surface yellow or pale brown, strongly and coarsely long straight-striate; fracture tough-fibrous; readily splitting. Inodorous; taste strongly astringent and bitter.

"*Powdered Rubus.*—Dark brown; fibers, long, irregular with thick, lignified walls from 0.010 to 0.045 mm. in width; numerous fragments composed of cortical parenchyma containing either rosettes of calcium oxalate the latter from 0.015 to 0.045 mm. in diameter or numerous simple to many-compound starch grains, the individual grains up to 0.015 mm. in diameter; fragments of cork tissue, the cells with light-brownish walls." *N. F.*

Its virtues depend chiefly upon tannin, which is an abundant constituent. The woody part of the roots is inert.

The fruit was described by the N. F. IV as "The fresh, ripe fruit of varieties of *Rubus nigrobaccus* Bailey or *Rubus villosus* Aiton (Fam. *Rosaceæ*). An aggregate fruit, ovate to oblong, rounded or slightly pointed, composed of numerous, shining black drupelets attached to an esculent receptacle; pericarp externally smooth or with only a few hairs (*R. villosus*), mesocarps fleshy, juice purple-red, endocarps hard, black, surfaces deeply wrinkled." *N. F. IV.*

Uses.—Dewberry and blackberry roots have long been a favorite domestic astringent remedy in *diarrheas*. Given in decoction, they are usually acceptacle to the stomach, without being offensive to the taste. The decoction may be prepared by boiling an ounce of the smaller roots, or of the bark of the larger, in a pint and a half of water down to a pint, of which from one to two fluidounces (30 to 60 cc.) may be given to an adult three or four times, or more frequently, during the twenty-four hours.

Dose, from fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Fluidextractum Rubi, *N. F.;* Syrupus Rubi, *N. F.*

RUMEX. N. F.

RUMEX [Yellow Dock, Curled Dock]

"Rumex is the dried root of *Rumex crispus* Linné, or of *Rumex obtusifolius* Linné (Fam. *Polygonaceæ*). Rumex contains not more than 5 per cent. of its stem bases or other foreign organic matter." *N. F.*

Yellow Dock; Curled Dock; Radix Lapathi; Rumex, *Fr.;* Ampferkraut, *G.;* Lapazio, *It.*

The docks are divided into two groups, one with hastate acid foliage and the other, much taller, with leaves which are neither acidulous in taste nor hastate in shape. The first group, sometimes known as the *sour dock,* or more frequently as *sorrel,* includes the *Rumex Acetosa* L. and the *R. Acetosella* L. which have been used as articles of diet in scurvy. They owe their acidity chiefly to acid potassium oxalate, although they also contain some tartaric acid. The amount of oxalic acid present is sometimes sufficient that when taken in large quantities they may produce poisonous effects. G. G. Flemyng (*L. L.,* i, 1896) reported the death of two sisters, aged respectively five and six and a half years, preceded by symptoms of oxalic acid poisoning as the result of the ingestion of sorrel leaves. Of the proper docks the roots of several species, besides those now official, have been employed. *R. Hydrolapathium* Hudson, which is the *R. aquaticus* of the old Dublin Pharmacopœia, is thought to be the *Herba Britannica* of the ancients, held in high esteem as a remedy for *scurvy. R. Britannica* L., *water dock,* was also formerly recognized by the U. S. Pharmacopœia (5th revision).

The official species, when full grown, are tall, (from two to four feet) perennial herbs with large leaves from six to twelve inches in length, the flowers being arranged in loose panicles. They may be readily distinguished from each other by their leaves which in *R. crispus* are lanceolate with strongly wavy-curled margins, whereas in *R. obtusifolius* they vary from ovate-cordate radical leaves to oblong-lanceolate cauline leaves with margins only slightly wavy-curled or frequently without curling. The commercial supplies of the drug used in the United States come chiefly from Virginia, North Carolina, Michigan and Indiana. They are both common in waste places throughout the United States—although they appear to have been naturalized from Europe—and often prove troublesome weeds.

Description and Physical Properties.—"*Unground Rumex.*—Nearly simple, slightly tapering, with few if any rootlets, somewhat twisted, up to 30 cm. in length and 7 cm. in diameter, externally reddish brown or grayish from adhering soil, finely annulate above, deeply wrinkled longitudinally, marked with small indented root scars which are often transversely elongated and with occasional stem scars or remains of stem, the latter being hollow and finely striated; leaf buds few, obconical; fracture short and dusty, somewhat fibrous; usually split longitudinally or cut into transverse pieces about 2 cm. in length. Odor, slight; taste, astringent and somewhat bitter.

"*Structure.*—A yellowish or brownish cortex and a whitish or yellowish wood which is finely radiate in the outer portion; cortex thick, with several layers of cork, beneath which is an interrupted row of lignified cells (*R. crispus*); a distinct cambium; and vascular bundles with few fibers.

"*Powdered Rumex.*—Calcium oxalate crystals in rosettes from 0.020 mm. to 0.065 mm. in diameter; numerous starch grains ellipsoidal or narrowly elongated, sometimes truncate, up to 0.028 mm. in length; lignified cells (in *R. crispus*) from 0.040 mm. to 0.200 mm. in diameter, with walls somewhat lamellated, from 0.008 mm. to 0.025 mm. in thickness and with few simple pores; fibers few, thin-walled with simple pores; tracheæ up to about 0.1 mm. in width with scalariform or reticulate thickenings of the wall; cork cells light brown." *N. F.*

Dock root has an astringent bitter taste with little or no odor.

Constituents.—Rumex contains tannin and a yellowish coloring matter, probably allied to anthocyanin. Beal and Okey (*J. Am. C. S.,* 1919, xli, 693) have found in it emodin (identical with that from cascara), monomethyl ether of emodin and chrysophanic acid; they surmise that these are, at least in part, in the form of glucosides. The total amount of emodin was about 0.17 per cent., of chrysophanic acid somewhat less. Tschirch and Weil (*A. Pharm.,* 1912, ccl, p. 20) find also *lapathinic acid,* $C_{20}H_{18}O_{14}$. According to Gilbert and Lereboulet, the *R. crispus* has the power of taking up iron present in the soil, and by watering plants with a solution of iron salts, roots may be obtained containing 1.5 per cent. of iron. In the sample examined by Tschirch and Weil there was present 0.379 per cent. of this element. From the root of *R. Nepalensis* Wall., which is largely used in Madras as an astringent for medicinal purposes and for dyeing, O. Hesse has separated three crystalline substances to which he gives the names of *rumicin, nepalin,* and *nepodin.* (*P. J.,* lvi; also *Proc. A. Ph. A.,* 1896, 551.) According to Tutin and Clewer (*Trans. Chem. Soc.,* 1910, xcvii), the *R. Eckolianus* Meissner, a South African herb, contains chrysophanic acid, emodin, and allied products, and is mildly purgative.

Dock root is mildly laxative and astringent and has been chiefly employed as an alterative in *syphilis* and chronic *skin diseases,* but its continued use is based on ancient tradition rather than any real therapeutic value. It is also employed locally in indolent skin diseases.

Dose, from thirty to sixty grains (2–4 Gm.).

Off. Prep.—Fluidextractum Rumicis, *N. F.*

SABAL. N. F.

SABAL [Saw Palmetto Berries]

"Sabal is the partially dried, ripe fruit of *Serenoa serrulata* (Michaux), Hooker filius (Fam. *Palmæ*). Sabal contains not more than 1 per cent. of foreign organic matter. Sabal should contain from 10 to 15 per cent. of its natural moisture when used for the manufacture of pharmaceutical preparations." *N. F.*

Saw Palmetto; Dwarf Palmetto.

The *saw palmetto* is a fan palm flourishing on the Atlantic coast from South Carolina to Jupiter Inlet, Florida, where it forms the so-called "palmetto scrub." According to Schneider, it is also found in the southern portions of California. The stem of saw palmetto is from 6 to 10 feet high, has a crown of large leaves, long petioled, with a circular fan-shaped leaf blade split at the edge into from 15 to 30 divisions, which are slightly cleft at their apices. The fruit is a one-sided, blackish-brown superior drupe, from half an inch to one inch long; ovoid-oblong in shape, with a somewhat wrinkled exterior, and a sweetish, not agreeable taste. It occurs in a large panicle which in some cases may weigh as much as nine pounds.

The fruits are gathered when fully mature, partially dried artificially and packed into barrels. To the contents of each barrel a small quantity of alcohol is added as a preservative. The commercial supplies are obtained largely from the Cape Canaveral district of Florida.

Description and Physical Properties.—"*Unground Sabal.*—Ellipsoidal or ovoid, occasionally compressed, from 1.5 to 3 cm. in length and from 1 to 1.5 cm. in diameter; externally brownish black to bluish black, smooth and somewhat oily, with a few large, more or less angular depressions due to the contraction of the sarcocarp, apex marked by the scar of the style, and the base either with a short stalk or stem-scar; epicarp and sarcocarp together forming a thin coriaceous shell enclosing a hard but thin endocarp, which is externally reddish brown and somewhat fibrous as is also the inner layer of the sarcocarp; inner layer of endocarp smooth, enclosing a hard, ellipsoidal or ovoid, somewhat flattened, reddish brown seed. Odor pronounced, aromatic; taste sweetish, aromatic, slightly acrid.

"*Powdered Sabal.*—Yellowish brown; parenchyma cells of sarcocarp containing a yellowish brown or brownish red, amorphous substance; whitish fragments of endosperm, the walls being considerably thickened and with large pores; stone cells occasional, nearly colorless, more or less tabular or irregular in shape, about 0.125 mm. in length, walls about 0.015 mm. in thickness, and with numerous simple or branching pores." *N. F.*

Kraemer gives an illustrated article on the pharmacognosy of the saw palmatto in the *Practical Druggist,* 1910, xxviii, p. 97.

By pressure they yield about 1.5 per cent. of a brownish-yellow to dark-red oil. Shermann and Briggs (*Ph. Archiv.,* 1899, 101, and *Ph. Rev.,* 1900, 217) found this to be composed of about 63 per cent. of free fatty acids and 37 per cent. of ethyl esters of these acids; there was no alkaloid present. Coblentz believed (*Proc. N. J. Ph. Assoc.,* 1895) that he found a volatile oil and an alkaloid, but Mann (*A. J. P.,* 1916, lxxxviii, p. 517) concluded that the so-called volatile oil was a mixture of the ethyl esters of the various fatty acids present due to the combination with the ethyl alcohol which is used as a preservative in shipping them. The fatty acids are caproic, caprylic, capric, lauric, palmitic and oleic.

Vanderkleed and E'we (*Proc. P. Ph. A.,* 1916, p. 284) contribute formulas for syrup of sabal and elixir of sabal with terpin hydrate. The latter is made as follows: Dissolve 1.75 Gm. of terpin hydrate in 40 cc. of fluidextract of sabal and 10 cc. of alcohol. Add 1 cc. of tincture of sweet orange peel, 0.2 cc. of solution of saccharin, 40 cc. of glycerin, and 100 cc. of syrup. This preparation will contain 8 grains of terpin hydrate and 184 grains of sabal in each fluidounce.

Uses.—Saw palmetto appears to exert a stimulant alterative action upon the mucous membrane of the genito-urinary tract, similar to but milder and less stimulant than is cubeb or copaiba, or the oil of sandal-wood. Like these drugs it also has the power of affecting the respiratory mucous membrane, so that it has been used not only in *chronic* and *sub-acute cystitis,* but also in *chronic bronchitis, laryngitis,* and the catarrhs which accompany *asthma, phthisis,* and other more serious diseases of the lungs. It has been affirmed that saw palmetto is capable of increasing the nutrition of the testicles and of the mammæ in functional atony of these organs, but this is very doubtful. It has been especially recommended in cases of *enlarged* *prostate* of old men; it is not probable that it has a direct influence upon the prostatic gland itself but there is much clinical testimony as to its value and it probably acts by reducing the catarrhal irritation and the relaxed condition of the mucous membrane of the bladder and urethra, which are almost universally present in prostatic hypertrophy.

Dose, ten to twenty grains (0.65–1.3 Gm.).

SALICINUM. U. S., Br.

SALICIN Salicin.

" A glucoside [$C_{13}H_{18}O_7$] obtained from several species of *Salix* and *Populus* (Fam. *Salicaceæ*)." *U. S.* " Salicin, $C_{12}H_{18}O_7$, is a crystalline glucoside, which may be obtained from the bark of various species of Salix, and of Populus." *Br.*

Orthohydroxybenzylglucoside; Salicine, *Fr.;* Salicin, *G.;* Salicina, *It.*

The discovery of salicin is claimed by Buchner of Germany, and Fontana and Rigatelli of Italy; but Leroux of France deserves the credit of having first accurately investigated its properties. Salicin is a glucoside of ortho-hydroxybenzyl-alcohol, and is found in the bark of *Salix Helix, S. pentandra, S. præcox* and probably some other species of willow and of the *Populus tremuloides* and *P. tremula* (see *Populi Gemmæ*). *Salix nigra* yields a different principle (see below).

To prepare salicin the ground bark is extracted with boiling water, concentrated in a vacuum still and the extract purified by precipitation with lead acetate. The excess of lead is removed by hydrogen sulphide and the filtrate is neutralized with ammonia and carefully concentrated to the crystallizing point. The crude salicin is decolorized with animal charcoal and recrystallization from water and finally from alcohol. Merck obtained 251 grains from 16 ounces of the bark and young twigs of *Salix Helix,* and Erdmann 300 grains from the same quantity of the bark of *Salix pentandra.* It may probably be obtained from any of the willow barks having a bitter taste. T. Fawssett states that the best material for preparing salicin is undoubtedly the willow peelings, obtained as refuse from a basket factory, and known in Belgium as " rood schors." David Brown states that the peelings are produced from *Salix fragilis,* while Crispo considers the source to be *Salix purpurea.* These peelings should be used soon after they are stripped from the twigs. (*P. J.,* June 6, 1903, 784.) A new glucoside called *salinigrin,* $C_{13}H_{16}O_7$, has been isolated from black willow bark. It has been shown to be a glucoside of metahydroxybenzaldehyde. Its melting point is 195° C. For a paper by Jowett on the percentage of salicin obtained from various kinds of willow bark, see *Y. B. P.,* 1902, 483, and 1903, 474.

Description and Physical Properties.—" Colorless, silky, shining needles or prisms, or a white, crystalline powder. It is odorless and has a very bitter taste. One Gm. of Salicin is soluble in 23.5 cc. of water and in 88.5 cc. of alcohol, at 25° C. One Gm. is soluble in 3.3 cc. of water at 80° C., and in 30 cc. of alcohol at 60° C. It is insoluble in chloroform and in ether.

" Salicin melts between 199° and 202° C. Its aqueous solution (1 in 30) is neutral to litmus paper, and is lævorotatory. Heat a small portion of Salicin in a test tube until it turns brown, add a few cc. of distilled water, and a drop of ferric chloride T.S.: a violet color is produced. With sulphuric acid Salicin gives a red color which disappears on the addition of distilled water. Heat gently about 0.1 Gm. of Salicin with about 0.2 Gm. of potassium dichromate and 2 cc. of diluted sulphuric acid: the fragrant odor of salicylic aldehyde is developed.

" Ash: not more than 0.05 per cent. Ten cc. portions of an aqueous solution of Salicin (1 in 50) yield no precipitate on the addition of 1 cc. of tannic acid T.S., picric acid T.S., or mercuric potassium iodide T.S. (*alkaloids*), and another 10 cc. portion is not colored violet by a drop of ferric chloride T.S. (*salicylic acid*). An aqueous solution of Salicin meets the requirements of the test for *heavy metals.*

" Preserve in well-closed containers." *U. S.*

" Colorless, shining, trimetric, tabular crystals, or white, crystalline powder. Taste very bitter. Soluble in 28 parts of *water,* and in 80 parts of *alcohol* (90 per cent.); insoluble in *ether.* Melting point from 200° to 201° C. Colored red by *sulphuric acid.* When 0.1 gramme is gently heated with 0.2 gramme of *potassium bichromate* and 2 millilitres of *diluted sulphuric acid* an odor recalling meadowsweet is developed. No appreciable ash." *Br.*

Salicin gives with concentrated sulphuric acid a bright red color; this is known as the *rutilin reaction.*

It belongs to the class of glucosides, being resolved by boiling with diluted hydrochloric and sulphuric acids into grape sugar and *saligenin,* according to the reaction:

$$C_{13}H_{18}O_7 + H_2O = C_6H_{12}O_6 + C_7H_8O_2$$

Saligenin, which is ortho-oxybenzyl alcohol, $C_6H_4(OH)CH_2OH$, is converted by further boiling with dilute acids into a resinous body, *saliretin,* $C_{14}H_{14}O_3$; this is a polymerized aldehyde of saligenin. Nitric acid produces with salicin at first two principles called respectively *helicin,* $C_{13}H_{16}O_7$, and *helicoidin,* $C_{26}H_{34}O_{14}$, and afterwards picric and oxalic acids. (*J. P. C.,* xxx, 43.) Distilled with potassium dichromate and sulphuric acid, salicin yields, among other products, a volatile oleaginous liquid, identical with one of the components of oil of spiræa, and recognized as *salicyl aldehyde,* $C_7H_6O_2$ (incorrectly called *salicylous acid*), while *saligenin,* $C_7H_8O_2$, is the alcohol, and *salicylic acid,* $C_7H_6O_3$, the acid corresponding. The synthesis of salicin has been effected by Michael (*A. J. P.,* 1879), who obtained first helicin by the reaction of acetochlorhydrose and salicyl aldehyde, and, by the action of nascent hydrogen upon this, salicin.

Saligenin (*salicyl alcohol*) has recently become a commercial article, a proprietary form being known as *salicaine.* Saligenin occurs as a white crystalline powder permanent in the air, soluble in water, alcohol, ether or the oils, melting at 85° to 86° C. Its taste is at first pungent and followed by a sense of numbness.

Uses.—Salicin acts upon the stomach probably as a simple bitter, and after absorption as a feeble and uncertain form of salicylic acid, since it is rapidly, although not completely, decomposed in the system, the products of its change appearing in the urine fifteen to thirty minutes after the ingestion of a single dose. The elimination is partly as salicin, partly as salicylic acid, partly as a salicyluric acid, and partly as saligenin. It has been highly recommended as a substitute for salicylic acid in *rheumatism* by Maclagan and others, but since it owes its activity to its conversion in the blood into salicylic acid and since this conversion is uncertain, salicin is inferior in power to the salicylates. By some it is believed to be less liable to upset the stomach. Salicin has been used as an antiperiodic. One or two drachms may be given in the intermission. Hirschfelder (*J. A. M. A.,* 1920, lxxv, 1770) has shown that saligenin possesses marked local anesthetic powers and has used it with satisfaction as a clinical anesthetic in strengths of from 4 to 10 per cent. It has the great advantage of being practically non-toxic.

Dose, of salicin, from ten to thirty grains (0.65–2.0 Gm.).

SAMBUCUS. N. F.

SAMBUCUS Sambuc. [Elder Flowers]

" Sambucus is the air-dried flower of *Sambucus canadensis* Linné, or of *Sambucus nigra* Linné (Fam. *Caprifoliaceæ*). Sambucus contains not more than 2 per cent. of foreign organic matter." *N. F.*

Elder; Sambuci Flores, *Br.,* 1898; Sweet Elder; Black Elder; Sureau, Fleurs de Sureau, *Fr.;* Flores Sambuci, *P. G.;* Holunder, Fliederblumen, *G.;* Sambuco, *It.;* Sauco, *Sp.*

The indigenous *common elder, Sambucus canadensis,* is a shrub from six to twelve feet high, with a branching stem, covered with a rough gray bark, and containing a large spongy pith. The small branches and leaf-stalks are very smooth. The leaves are opposite, and pinnately-compound with usually seven leaflets The flowers are small, white, and disposed in loose cymes; the cream-colored corolla is wheel-shaped, with five stamens on the tube. The fruits are small, globular, black berry-like drupes which are edible when mature. The shrubs grow in low, moist grounds, along fences, and on the borders of small streams, throughout the United States, from Canada to the Carolinas, and westward as far as Arizona and Texas. It flowers from May to July, and ripens its fruit early in autumn.

The *Sambucus nigra,* of Europe, differs from the American most obviously in its size, approaching in height that of a small tree. The stem is much branched towards the top, and has a rough whitish bark. The leaves may show 3–7 leaflets but usually possess 5. The flowers are small, whitish and in five-parted cymes. The ovary consists of but three carpels, there being usually four cells in *S. canadensis* L. The berries are large in the European elder, globular, and blackish-purple when ripe. G. De Sanctis (*Gazz. Chim. Ital.,* 1895, xxv, 1, vol. xlix) obtained coniine from the leaves and stems of *Sambucus nigra.*

The flowers have an aromatic though rather heavy odor. The berries as well as other parts of the plant are employed in domestic practice.

Description and Physical Properties.—" Small, from 2 to 3 mm. in width, shriveled; calyx superior, five-lobed; corolla cream colored to brownish yellow, rotate, flat or slightly campanulate, regularly five-lobed; stamens five, inserted at the base of the corolla and alternating with its lobes, filaments lender, anthers oblong, yellow; pollen ellipsoidal or tetrahedral and rounded, covered with finely punctate markings, having three pores and up to 0.23 mm. in diameter, Odor faintly sweet and aromatic; taste slightly bitter." *N. F.*

The flowers yield their active properties to water by infusion, and when distilled give over a small proportion of volatile oil, which on cooling assumes a butyraceous consistence and contains an appreciable portion of ammonia. The *berries* are nearly inodorous, but have a sweetish, acidulous taste, dependent on the presence of saccharine matter and malic acid. Their expressed juice is susceptible of fermentation, and forms a vinous liquor used in northern Europe. It is colored violet by alkalies, and bright red by acids, and the coloring matter is precipitated blue by lead acetate. The *inner bark* is without odor. The *bark* of the elder contains tannin, valeric (*viburnic*) acid, resin, etc. (Traub, *A. J. P.,* 1881, p. 392). The resin, according to Simon (*Ann. Pharm.,* xxxi, p. 262), in doses of twenty grains is cathartic and emetic. Lloyd found in the flowers a white substance—*eldrin,* which turned a deep yellow on the addition of alkalies which he believed to be the coloring matter of white flowers (*A. J. P.,* 1921, xciii, p. 40). As far as we know, no substance has been found in the flowers suggesting any physiologically active principle. J. B. Metzgar made a partial examination of the fruit and found sugar, gum, tannin, fat, and a resinous body. (*A. J. P.,* 1881, p. 553.) It was also examined by F. F. Lyons (*A. J. P.,* 1892, p. 1), who found 0.5 per cent. of a volatile oil, an amorphous yellow compound of a glucosidal character, and a tannin. The volatile oil of elder flowers was examined by W. J. Bush & Co. (*C. D.,* 1897, 53.) It has the sp. gr. 0.827, and is solid at ordinary temperatures like oil of rose. The liquid portion possesses the fragrance of fresh elder blossoms.

Uses.—Elder flowers have been esteemed diaphoretic and diuretic and used in febrile complaints and also as an alterative in *syphilis* and *rheumatism.* There is, however, no reason to suspect that they possess any real curative properties. The berries, bark and root, however, appear to possess some laxative principles and especially the last named has been used as a hydragogue in *dropsy.*

Dose, from thirty to sixty grains (2–4 Gm.).

Off. Prep.—Fluidextractum Stillingiæ Compositum, *N. F.;* Species Laxativæ, *N. F.;* Syrupus Stillingiæ Compositus, *N. F.*

SANGUINARIA. N. F.

SANGUINARIA Sanguin. [Bloodroot]

"Sanguinaria consists of the dried rhizome and roots of *Sanguinaria canadensis* Linné (Fam. *Papaveraceæ*). Sanguinaria contains not more than 2 per cent. of foreign organic matter." *N. F.*

Blood-root, Red-root, Puccoon, Red Indian-plant, Puccoon-root, Coon-root, White puccoon, Pauson, Snakebite, Sweet-slumber, Red Puccoon, Tetterwort, Red Indian Paint; Sanguinaire, *Fr.;* Blutwurzel, *G.*

Sanguinaria canadensis, or, as it is sometimes called, *red puccoon,* is a perennial herb native to the rich open woods of North America. The rhizome is horizontal, abrupt, often contorted, about as thick as the finger, two or three inches long, fleshy, of a reddish-brown color on the outside, and emitting a reddish latex, when broken in the recent state. It is furnished with numerous slender roots, and makes offsets from the sides, which succeed the old plant. From the end of the rhizome arise the scape and leafstalks, surrounded by the large sheaths of the bud. These spring up together, the folded leaf enveloping the flower-bud, and rolling back as the latter expands. The leaf, which stands upon a long channelled petiole, is reniform, somewhat heart-shaped, palmately 7- to 9-lobed, smooth, yellowish green on the upper surface, paler or glaucous on the under, and strongly marked by orange-colored veins. The scape is erect, round, and smooth, rising from a few inches to a foot, and terminating in a single white flower. The calyx is two-leaved and deciduous. The petals, varying from seven to fourteen, but usually about eight in number, are spreading, ovate, obtuse, concave, mostly white, but sometimes slightly tinged with rose or purple. The stamens are numerous, with yellow filaments shorter than the corolla, and orange oblong anthers. The ovary is oblong and compressed, with a sessile, persistent stigma. The capsule is oblong, acute at both ends, one-celled, two-valved, and contains numerous oval, reddish-brown seeds. The whole plant is pervaded by an orange-colored sap, which flows from every part when broken, but is of the deepest color in the rhizome. The bloodroot is one of the earliest and most beautiful spring flowers of the northern United States, growing abundantly in loose, rich soils and shady situations. After the fall of the flower the leaves continue to grow, and by the middle of summer have become so large as to give the plant an entirely different aspect. Except the seeds, all parts of the plant are active.

The rhizome should be collected at the time of, or immediately subsequent to the flowering of the plant, for it is at this time that it possesses the largest amount of alkaloids.

Description and Physical Properties.—"*Unground Sanguinaria.*—Of horizontal growth, occasionally branching, more or less cylindrical, somewhat flattened, from 2 to 7 cm. in length and from 5 to 15 mm. in diameter; externally dark brown, slightly annulate, with a few stem-scars on the upper surface and numerous root-scars or more or less broken filiform roots on the lower surface; fracture short, most of the rhizomes showing a brownish red internal color, somewhat waxy and with numerous small circular, yellowish fibrovascular bundles within about 1 mm. of the epidermis and a very large pith. Odor slight; taste persistently acrid and bitter.

"*Structure.*—Rhizome; an outer layer of a single row of thin-walled epidermal cells; a cortex of from 10 to 15 rows of thin-walled parenchyma cells containing numerous starch grains, or a small amount of fixed oil; a zone of cambium, most of which is interfascicular; a narrow circular zone of small collateral fibrovascular bundles, bearing parenchyma cells; latex cells containing a red or orange colored secretion, either isolated or connected into irregular chains and distributed among the parenchymatous cells of the middle bark and pith; sections treated with glycerin for twenty-four hours show spheroidal aggregates of crystals in the secretion cells or latex tubes.

"*Powdered Sanguinaria.*—Brownish red, sternutatory; exhibits numerous starch grains, from 0.003 to 0.020 mm. in diameter, being mostly single, seldom 2- to 3-compound, the individual grains nearly spherical or ovoid, sometimes more or less plano-convex, somewhat resembling those of wheat starch in outline but polarizing light more strongly; numerous fragments of short latex cells with reddish brown resinous masses; tracheal fragments few, having numerous slit-like pores." *N. F.*

For an interesting microscopical description of the rhizome by E. S. Bastin, see *Pharm.,* 1885, p. 201. Sanguinaria has a faint odor, and a bitter, very acrid taste, the pungency of which remains long in the mouth and fauces. Lloyd states that sanguinaria is both a contamination and an adulterant of hydrastis. (*Pharm. Rev.,* 1905, xxiii, p. 332.) It yields its virtues to water and alcohol.

Constituents.—G. König (*A. J. P.*, 1891, p. 457) found *chelerythrine*, $C_{21}H_{17}O_4N$, which is present in greatest quantity, *sanguinarine*, $C_{21}H_{15}O_4N$, *β- and γ-homochelidonine*, $C_{21}H_{23}O_5N$, and *protopine*, $C_{20}H_{19}O_5N$. Chelerythrine crystallizes with a molecule of alcohol which is not separated at 150° C. It is identical with the alkaloid extracted from *Chelidonium majus* and *Stylophorum diphyllum.* (See Part II.) The salts are lemon-yellow. Sanguinarine is very similar to chelerythrine in its properties. It crystallizes with one molecule of H_2O, and melts at 211° C. It also crystallizes with one molecule of alcohol. Its salts are red. The base named γ-homochelidonine is probably identical with that separated by Selle from *Chelidonium majus.* The fourth alkaloid, protopine, has been prepared from *Chelidonium majus,* from *Sanguinaria canadensis,* and from opium, all three of the specimens being identical. It melts at 204° C. Beringer and Homerberg (*A. J. P.*, 1915, p. 97) found the alkaloidal content of the rhizome to range from 4.7 to 7.0 per cent. and of the rootlets to be about 1.8 per cent.; it was highest in the rhizome at the time of flowering. The virtues of the root are said to be rapidly deteriorated by time. *Sanguinarinic acid* L. C. Hopp has shown to be a solution of impure citric and malic acids.

Schlotterbeck (*Ph. Rev.*, 1900, 358) examined sanguinarine nitrate of commerce and found it to consist mainly of chelerythrine, with some sanguinarine and traces of protopine and homochelidonine; he believes that chelerythrine should be called sanguinarine. For methods of assay of sanguinaria, see *A. J. P.*, 1896, 305; *M. R.*, 1900, 451; *Proc. A. Ph. A.*, 1903, 284; *A. J. P.*, 1913, p. 395.

Uses.—Sanguinaria is an active local irritant, in large doses producing nausea and vomiting. When snuffed up the nostrils it excites much irritation and sneezing. According to the investigations of Meyer (*A. E. P. P.*, 1892, xxix, p. 397), sanguinarine is an active stimulant to the spinal cord producing in frogs strychnine-like convulsions followed, after very large doses, by complete paralysis. It also stimulates the respiratory center, increasing both the depth and rate of the breathing. By virtue of a stimulant action upon the vasomotor center it causes a rise in blood pressure which, with toxic doses, is followed by a fall in the blood pressure, due to weakening of the heart action. It also excites the flow of saliva and increases intestinal peristalsis. In toxic doses it acts as a poison to the voluntary muscles. When locally applied it causes at first pain, followed by a local anesthesia.

Chelerythrine, although present in larger amounts in sanguinaria, is a much less poisonous alkaloid than sanguinarine and it is probable that it plays a rôle of relatively small importance in the action of the whole drug. The physiological action of chelidonine has been studied by Meyer (*A. E. P. P.*, 1892, xxix, 397) and by Hanzlik (*J. A. M. A.*, 1920, lxxv, 1324 and *J. P. Ex. T.*, 1921, xviii, 63). It is feebly narcotic, according to Hanzlik having less narcotic power than papaverine. Its toxic action is comparatively low, the minimal lethal dose for the lower animals being between 0.3 and 0.4 Gm. per kilo. Its most important action is a depressant effect on the involuntary muscles; Hanzlik found that it not only produced a relaxation in normal involuntary muscles but antagonized the effect of such stimulants of these muscles as barium, pilocarpine, etc. Because of this action on muscle tissue it lowers blood pressure by relaxing the arteries and weakening the cardiac contractions. Beta-homochelidonine, the third most important alkaloid, has a feeble narcotic effect, produces cerebral convulsions, but does not increase reflex activity. It is an active local anesthetic without the irritant effect of sanguinarine.

Sanguinaria is used chiefly as an expectorant, especially in the treatment of subacute or *chronic bronchitis.* Whether it possesses any beneficial action for this purpose except that which may be attributed to its nauseating effect,—due largely to irritation of the gastric mucosa—seems doubtful. It has also been recommended by Graber (*J. A. M. A.*, 1907, xlix, p. 705) as a local application in chronic *eczema,* especially when secondary to *varicose ulcers.*

In toxic quantities sanguinaria produces burning in the epigastrium with vomiting, tormenting thirst, faintness, vertigo, dimness of vision, and alarming prostration. Twenty grains (1.3 Gm.) are said to usually act as a violent emetic. (For fatal cases see *Am. J. M. S.*, N.S., ii, p. 506.)

The alkaloid sanguinarine has been used in doses of from one-twelfth to one-sixth of a grain (0.005–0.01 Gm.). Sanguinaria is rarely given in substance.

Dose, two grains (0.13 Gm.).

SANTALUM ALBUM. N. F.

SANDAL WOOD Santal Alb. [White Sandalwood]

"Sandalwood is the heartwood of *Santalum album,* Linné (Fam. *Santalaceæ*). Sandalwood yields not less than 3.5 per cent. of volatile oil, and contains not more than 1 per cent. of foreign organic matter." *N. F.*

Lignum Santali Citrinum; Yellow Sandalwood; Santal Citrin, Bois de Santal blanc, *Fr.;* Gelbes Sandelholz, *G.;* Sandalo Cetrino (Leno de), *Sp.*

For description of this tree see under *Oleum Santali.*

Description and Physical Properties.—"In billets, pieces or chips of varying shapes and sizes, heavy, hard but splitting easily, color light yellow to light brown. Odor characteristic, aromatic, persistent; taste peculiar, strongly aromatic.

"*Structure.*—Transverse sections yellow to light reddish brown, with alternating light and dark concentric zones nearly equal in width, with numerous tracheæ and traversed by many very narrow medullary rays; the medullary rays from two to four cells wide, the cells thick-walled and radially marked; the wood wedges consisting largely of wood fibers with pointed ends and containing a few starch grains, large parenchyma and thick-walled oil secretion vessels and cells containing single crystals of calcium oxalate up to 0.030 mm. in length; the oil in globules adhering to the walls of the ducts and parenchyma cells and especially rich in the medullary ray cells." *N. F.*

Sandal wood owes its therapeutic virtues solely to its volatile oil (see *Oleum Santali*). It is not used in substance.

Dose, sixty grains (4 Gm.).

Off. Prep.—Fluidextractum Santali Albi, *N. F.;* Elixir Sabal et Santali Compositum, *N. F.;* Tinctura Sabal et Santali, *N. F.*

SANTALUM RUBRUM. U. S. (Br.)

RED SAUNDERS Santal. Rub.

"Red Saunders is the heart-wood of *Pterocarpus santalinus* Linné filius (Fam. *Leguminosæ*)." *U. S.* "Red Sanders Wood is the heart-wood of Pterocarpus santalinus, *Linn. f.*" *Br.*

Pterocarpi Lignum, *Br.;* Red Sanders Wood; Lignum Santali Rubri; Rasura Santalum Ligni; Red Sandal Wood; Red Santal Wood; Ruby Wood; Santal rouge, *Fr.;* Santelholz, Rothes Santelholz, *G.;* Sandalo rojo (Leno de), *Sp.*

Pterocarpus santalinus is a large tree, with alternate branches, and trifoliate leaves, each leaflet being ovate, somewhat notched at the apex, smooth on the upper surface, and hoary beneath. The flowers are yellow in axillary spikes, and have a papilionaceous corolla, of which the vexillum is obcordate, erect, somewhat reflexed at the sides, toothed and waved, the alæ spreading with their edges apparently toothed, and the carina oblong, short, and somewhat inflated. The fruit is a 2-seeded legume. The tree is a native of India, attaining the highest perfection in mountainous districts, and inhabiting especially the mountains of Coromandel and Ceylon. It is cultivated in Southern India and in the Philippine Islands.

The wood comes in heavy, irregular, roundish or angular billets of various size and thickness, externally brown from exposure, internally of a deep blood-red color, on transverse section variegated with zones of a lighter red. The structure is heavy, compact, and fibrous. In the pharmacies red saunders is usually kept in the shape of small chips, or raspings, or coarse powder, of a deep reddish-brown color, slightly astringent taste, and when rubbed of a faint peculiar odor. It has little odor or taste.

Description and Physical Properties.—"*Unground Red Saunders.*—Usually in the form of a coarse powder, of a purplish to brownish-red color and nearly odorless and tasteless.

"*Powdered Red Saunders.*—Wood-fibers numerous, mostly irregular in outline, with sharply pointed and occasionally forked ends, from 0.30 to 0.75 mm. in length, walls very thick, porous, yellowish, unevenly thickened and strongly lignified, and the lumina filled with a fine, granular, content; tracheæ few with simple or bordered pores and filled with light lemon-yellow, resinous masses; occasionally fragments showing medullary ray cells in narrow elliptical groups 1-cell wide and from 3- to 6-cells deep; crystal-fibers few with calcium oxalate in the form of monoclinic prisms, from 0.008 to 0.020 mm. in length. Mounts in chloral hydrate T.S. are of a deep, rich red color.

"Add 0.5 Gm. of Red Saunders to 10 cc. of alcohol: the solution becomes distinctly red. Add 0.5 Gm. of Red Saunders to 10 cc. of ether: the solution assumes an orange-yellow color and when held in a bright light shows a distinct greenish fluorescence.

"Add 0.5 Gm. of Red Saunders to 10 cc. of water: the solution remains clear and colorless." *U. S.*

"Imported in irregular logs or billets, freed from the pale sapwood; reddish-brown or blackish-brown externally, deep blood-red internally; hard, but easily split longitudinally. In transverse section, narrow, closely approximated, reddish medullary rays traversing a nearly black wood with scattered, large, isolated vessels. Coloring matter readily soluble in *alcohol* (90 per cent.), but almost insoluble in *water*. Odor of the warmed Wood faintly aromatic; taste very slightly astringent." *Br.*

It imparts a red color to alcohol, ether, and alkaline solutions, but not to water, and a test is thus afforded by which it may be distinguished from some other coloring woods. The alcoholic tincture produces a deep violet precipitate with ferrous sulphate, a scarlet with mercuric chloride, and a violet with the soluble salts of lead. The coloring principle, which was separated by Pelletier and called by him *santalin,* is of a resinous character, scarcely soluble in cold water, more so in boiling water, very soluble in alcohol, ether, acetic acid, and alkaline solutions, but slightly in the fixed and volatile oils, with the exception of those of lavender and rosemary, which readily dissolve it. It is precipitated when acids are added to the infusion of the wood, prepared with an alkaline solution. It is also called *santalic acid* and has the formula $C_{17}H_{16}O_6$. The formula $C_{23}H_{18}O_6(OCH_3)_2$ has also been given to it. (*Ann. Ch. Ph.,* lxxiv, p. 226.) Weidel (*Wien. Akad. Ber. Ph.,* lx, p. 388), by extracting the red saunders with potassium hydroxide, precipitating with hydrochloric acid, and again extracting from the purified precipitate with ether, obtained a colorless crystalline principle, which he calls *santal,* $C_8H_6O_3 + \frac{1}{2}H_2O$.

Cazeneuve and Hugonneng (*C. R. A. S.,* civ, 1725) have described two crystalline principles which they have extracted from red saunders, *pterocarpin*, $C_{20}H_{16}O_6$, and *homopterocarpin*, $C_{24}H_{24}O_6$, of which the former fuses at 152° C., and the latter at from 82° to 86° C.

The wood has no medicinal virtues, and is employed solely for the purpose of imparting color.

SANTONINUM. U. S., Br.

SANTONIN Santonin.

"The inner anhydride [$C_{15}H_{18}O_3$] of santoninic acid." *U. S.* "Santonin, $C_{15}H_{18}O_3$, is a crystalline principle which may be obtained from santonica, the dried unexpanded flowerheads of Artemisia maritima, *var.* Stechmanniana, *Besser.*" *Br.*

Santonine, Anhydride Santonique, *Fr. Cod.;* Santoninum, *P. G.;* Santonin, *G.;* Santonina, *It., Sp.*

The U. S. X no longer gives the botanical source of santonin. The U. S. IX gave it as *Artemisia pauciflora* (Ledebour) Weber (*A. Cina* Berger) but the Br. gives it from the *A. Maritima* var. *Stechmanniana* Besser. As a matter of fact santonin is found in several species of the genus *Artemisia;* Greenish and Pearson have found it in the *A. brevifolia* which grows in western Thibet (*P. J.*, 1921, cvi, p. 2) and Viehœver and Capen (*A. J. P.*, 1922, xciv, p. 446) in the *A. Mexicana* and *A. Neo Mexicana* which grow in Mexico and southwestern United States. It is probable even that several plants have served as a commercial source of the drug.

Formerly the flowers were largely exported from the Levant and were official in the U. S. VIII and also in the Br. 1867 under the name of *Santonica.* This was commonly called *wormseed,* or *Levant wormseed,* although it is not the seeds but the unexpanded flower heads from which the drug is derived. The *A. Cina* is a small semi-shrubby perennial, from whose oblique, knotted rootstalks arise numerous leafy shoots and flowering stems. The glabrous and woody stems bear on their many branches numerous small (one inch long) bi- to multi-pinnatifid leaves, while the leaves of the flowering stems are very minute, the upper ones simple. The flower heads are small, numerous, one-tenth of an inch long, with from twelve to eighteen involucral scales, and from three to five tubular flowers. The plant varies very greatly, and several species have been made out of its varieties. The plant grows in Persia and Turkestan and the flower-buds are collected in July and August. The Levant wormseed was officially described as "heads 2 to 4 mm. long, oblong-ovoid, slightly flattened, obtuse, consisting of an involucre of about 12 to 18 closely imbricated, glandular scales with broad midribs, enclosing 4 to 5 rudimentary florets. Santonica has the appearance of a granular, yellowish-green or greenish-brown, somewhat glossy powder; odor strong, peculiar, somewhat camphoraceous; taste aromatic and bitter." *U. S. VIII.* Astolfi (*Ph. Ztg.*, 1893, 333) gives the following test for recognizing adulteration of santonica. 1 Gm. of the suspected drug is finely pulverized and then agitated with 10 cc. of absolute alcohol; the whole is heated to boiling, filtered, a piece of potassium hydroxide is added to the filtrate, which is then heated. If the drug is pure, the liquid will acquire a pronounced red color; if falsified, the color will be yellow; and if no santonica be present, the liquid will be colored but faintly, if at all.

Attention was called by C. H. LaWall (*J. A. Ph. A.*, 1913, p. 596) to a variety of santonica that has appeared upon the market, which seems to be devoid of santonin or to contain not more than traces. He proposes a simple test which may be applied directly to the drug as a preliminary procedure and thus avoid the necessity of going through the long assay process if the sample is valueless: Place 5 Gm. of santonica (whole or ground) in a test tube, add 5 cc. of spirit of nitrous ether and boil gently. No color should be developed, or not more than a slight greenish yellow color due to the solvent action of the spirit on the resins of the drug. Now add 10 drops of alcoholic solution of potassium hydroxide. In an active drug a rose red color is developed in direct proportion to the amount of santonin present. A similar report has been made by van Itallie (*Ph. Wb.*, 1917, liv, 304). For a method of valuing santonica, by Dragendorff, see *Proc. A. Ph. A.*, xxvi, 229. For Ehling's process for valuing santonica, see *U. S. D.*, 19th ed., page 1085.

Wormseed contains, besides its chief principle santonin, a volatile oil—which consists chiefly of cineol with some dipentene—and, according to Merck (*P. J.*, 1896, 484), another crystalline principle, *artemisin,* $C_{15}H_{18}O_4$, which is apparently a *hydroxy-santonin.* The proportion of santonin reaches its maximum of from 2.5 to 3.5 per cent., just before the flower begins to open. After blooming the flowers rapidly lose this principle.

The present U. S. P. and the Br. Ph., 1898, very properly omit processes for the preparation of santonin. (See *U. S. D.*, 17th ed., 1191; also 19th ed., p. 1085.)

It has been intimated that the large manufacturers of santonin, abroad, first distil off from the santonica its volatile oil, which has some commercial value in Europe, and that the process for preparing santonin is probably facilitated thereby, the affinity of the oil for the santonin making the latter more difficult of purification.

Santonin was lowered in price after the erection of a factory in Tschimkent, Turkestan, where the Levant wormseed can be furnished cheaply; the process used there is to treat the wormseed with milk of lime; the calcium santoninate formed is next treated with sodium hydroxide and carbon dioxide; the sodium santonate is then decomposed by sulphuric acid.

The acid liquid, on refrigeration, deposits the santonin in crystals.

Crude santonin or calcium santoninate is usually shipped from the Levant to the countries where it is purified and marketed.

Description and Physical Properties.—"Colorless, shining, flattened rhombic prisms or a white, crystalline powder. It is colorless, and nearly tasteless at first, but afterwards develops a bitter taste. It is stable in the air, but rapidly becomes yellow on exposure to light. Santonin is almost insoluble in cold water, and only slightly soluble in boiling water. One Gm. of Santonin is soluble in 43 cc. of alcohol, 1.7 cc. of chloroform, and in 110 cc. of ether, at 25° C. One Gm. is soluble in 6.5 cc. of boiling alcohol.

"Santonin melts between 169° and 171° C. Its solution in alcohol (1 in 50) is neutral to litmus paper. Its solutions are lævorotatory. Heat about 0.2 Gm. of Santonin with 2 cc. of alcoholic potassium hydroxide T.S.: a red color is developed. Shake about 0.01 Gm. of Santonin with a cool mixture of 1 cc. each of sulphuric acid and distilled water, heat the solution to 100° C., and add a drop of dilute ferric chloride solution (1 volume of ferric chloride T.S. to 10 volumes of distilled water): a violet color results.

"Ash: not more than 0.1 per cent. The solution of 0.1 Gm. of Santonin in 2 cc. of sulphuric acid is not darker than pale yellow (*readily carbonizable substances*). Boil 0.5 Gm. of Santonin with 20 cc. of distilled water and 2 cc. of diluted sulphuric acid, cool, and filter: the addition of mercuric potassium iodide T.S. or of iodine T.S. to 10 cc. of the filtrate, mixed with 10 cc. of distilled water, produces no cloudiness even after standing for three hours (*alkaloids*).

"Preserve in well-closed containers protected from light." *U. S.*

"Colorless, flat, rhombic prisms. Taste slightly bitter. Almost insoluble in *water;* soluble in 2.5 parts of *chloroform,* and in 50 parts of *alcohol* (90 per cent.). Melting point 170° C. Sunlight renders it yellow. Added to warm *alcoholic solution of potassium hydroxide* it yields a violet-red color. Insoluble in diluted mineral acids. No appreciable ash." *Br.*

For a test for santonin, see *Ph. Era,* 1898, 210. The air has no effect upon it, but it becomes yellow on exposure to sunlight. According to Sestini, the santonin is changed, through the influence of light, into formic acid, and an uncrystallizable substance, much more soluble in alcohol and ether than santonin itself, which he calls *photosantonic acid,* $C_{15}H_{22}O_5$, and a red resinous substance. If the santonin be in alcoholic solution, after several months of exposure to sunlight it is changed into the ethyl ether of photosantonic acid. In its relations to polarized light it is very strongly lævogyrate, and retains this property with acids, though losing it entirely when combined with salifiable bases.

When warmed with alkalies, santonin is changed into monobasic *santoninic acid,* $C_{15}H_{20}O_4$, while concentrated baryta water changes it on prolonged boiling into the isomeric *santonic acid;* but Hesse (*B. Chem. G.,* vi, 1280) has shown santonin to be the anhydride of *santoninic acid,* and prepared this acid by adding an excess of diluted hydrochloric acid to an aqueous solution of the sodium salt, and adding ether, from which the acid may be recovered by evaporation. When santoninic acid is heated to 120° C., it is resolved into santonin and water. It has a strongly acid reaction, and decomposes sodium and calcium carbonate.

Sodium santoninate (*Sodii Santoninas*) was official in the *Pharmacopœia Germanica* of 1872, and was recognized in the U. S. P., 1880. It is a colorless crystalline substance freely soluble in water. It was very properly dropped at the U. S. P., 1890 revision, because it is more easily absorbed than santonin in crystals, and therefore much more dangerous to the patient and much less destructive to intestinal worms. For method of preparation and tests of purity, see *U. S. D.,* 19th ed., p. 1243.

For a history with a review of the chemical constituents and decomposition products of santonin see *Y. B. P.,* 1901, 487.

Cannizzaro and Carnelutti (*B. Chem. G.,* xvi, 2685) have shown that santoninic acid, an isomer, breaks up on high heating into *propionic acid,* $C_3H_6O_2$, and *dihydrodimethylnaphthol,* $C_{10}H_7(CH_3)_2.OH$, and distilled over zinc dust it gives a mixture of dimethylnaphthol, $C_{10}H_5(CH_3)_2.OH$, dimethylnaphthalene, $C_{10}H_6(CH_3)_2$, and propylene. *Santonone,* $(C_{15}H_{17}O_2)_2$, a decomposition product of santonin, is made by gradually adding zinc dust to a hot solution of santonin in acetic acid, preferably in the presence of a little platinum tetrachloride. It forms silky white needles, is very soluble in benzene, less so in hot alcohol, ether or diluted acetic acid, and insoluble in water.

Uses.—Santonin is used chiefly as a vermifuge. Against the *round worm* it is generally esteemed as one of the most efficient remedies we possess, its ease of administration as well as its certainty of action making it peculiarly valuable. The coarse crystals should be preferred to the powder as being less readily dissolved, and therefore less likely to be absorbed from the stomach. It may be well administered to children in the form of lozenges made with sugar and tragacanth (for formula, see *A. J. P.,* vi, 124), which if the unbroken crystals are used, can be rendered very pleasant to the taste, so that children will eat them as candy. The dose of santonin for a child two years old is from one-fourth to one-half grain (0.016–0.032 Gm.). To older patients it is best given by enclosing in gelatin capsules. It should always be followed by a cathartic, calomel being perhaps best; although castor oil is sometimes used it should be avoided as likely to increase the absorption. The santoninates, or any combination of santonin with alkali carbonates or hydroxides, should be sedulously avoided as vermifuges, because of the liability of their being absorbed.

Santonin has been recommended internally in a large variety of conditions, but has failed to establish itself in any of them. It was at one time used as a stimulant to the optic nerve in *amaurosis,* especially due to *nicotinism.* Drake (*S. M.,* 1907, p. 550) reports favorably on its use in *dysentery,* and Negro has used it as an analgesic in *tabes* and various forms of *neuralgia.* The statements of Sejournet that it would diminish the output of sugar in *diabetes* have been contradicted by the observations of Walterhoefer. (*B. K. W.,* 1911).

According to Walter G. Smith, the yellow color imparted to urine by santonin is distinguished from that produced by other substances by becoming purplish-red on the addition of ammonia or other alkali. (*P. J.,* Dec., 1870.) For researches upon the character of the urinary coloring matter, consult the same paper.

In overdose santonin produces a poisoning whose symptoms are giddiness, mental apathy or stupor, great paleness and coldness of the surface, vomiting, profuse sweating, trembling, mydriasis, and finally loss of consciousness, with convulsions, often violent and accompanied by opisthotonos and emprosthotonos and failure of respiration. Xanthopsia is an early and characteristic symptom. All objects appear discolored, generally yellow, but frequently green, and sometimes blue. At the same time the urine is tinged of a yellow or a green color. These effects were formerly thought to be due to the staining of the aqueous humor but are more probably to be attributed to a direct action on the retina. In regard to the minimum fatal dose, two grains are said to have killed a feeble child five years old, and a child of seven years is said to have suffered death from six grains after development of hematuria (*B. G. T.,* lxxiv, 362); four grains produced very serious symptoms in a child four years old. (*P. J.,* ix, 696.) The xanthopsia and discolored urine make the diagnosis of santonin poisoning easy. According to Crouzel the addition of alkalies to the urine will demonstrate the presence of santonin, before the coloration is pronounced, by the development of a characteristic carmine-red tint.

Dose, two to four grains (0.13–0.26 Gm.).

Off. Prep.—Tabellæ Santonini, *Br.;* Tabellæ Santonini Compositi, *N. F.*

SAPO. U. S. (Br.)

SOAP [Olive Oil Castile Soap]

"Soap prepared from olive oil and sodium hydroxide." *U. S.* "Hard Soap is soap made from sodium hydroxide and olive oil; it contains not more than 30 per cent. of water." *Br.*

Sapo Durus, *Br.;* Hard Soap, Castile Soap; Sapo Amygdalinus; Sapo Medicinalis, *Fr. Cod.;* Savon medicinal, Savon blanc, *Fr.;* Sapo medicatus, *P. G.;* Medizinische Seife, Oel-Sodaseife, Seife, Spanische Seife, *G.;* Sapone medicinale, S. amigdalino, Sapone duro, *It.;* Jabon de aceite de olivas, Jabon, *Sp.*

Soap is believed to have been discovered by the Gauls shortly after the beginning of the Christian Era. For a history of soap and of cleansing methods used by ancient races, see papers by Abraham (*J. A. Ph. A.,* 1916, v, 205) and by Cook (*A. J. P.,* 1925, xcvii, 398).

Soaps embrace all those compounds which result from the reaction of salifiable bases with fats and oils. Fats and oils, as has been explained under the titles *Adeps* and *Olea,* consist generally of three glyceryl esters, two solid, differing in fusibility, called stearin and palmitin, and one liquid, called olein. Stearin is found most abundantly in fats which are firm and solid, as suet and tallow, and palmitin and olein in the oils. When the fats and oils undergo saponification by reaction with a salifiable base, these three esters are decomposed into the fatty acids called stearic, palmitic, and oleic acids, which unite with the base to form the soap, and into glycerin (glycerol), which is set free. Hence, it is obvious that soaps are mixed stearates, palmitates, and oleates of certain bases.

Soaps are divided into the soluble and the insoluble. The soluble soaps are combinations of the fatty acids with sodium, potassium or ammonium hydroxides; the insoluble consist of the same acids united with other earths or metallic oxides. It is the soluble soaps only that are detergent, and to which the name *soap* is usually applied. Several of the insoluble soaps are employed in pharmacy, as, for example, the lead monoxide soap, or lead plaster, and the lime soap, or lime liniment. (See *Emplastrum Plumbi Oleatis* and *Linimentum Calcis.*) The two official soaps are of the soluble kind. One is a soda soap, made with olive oil (Castile soap), the other a potassium soap (soft soap). (See *Sapo Mollis.*)

The consistence of the fixed alkaline soaps depends partly on the nature of the oil or fat, and partly on the alkali present. Soaps are harder the more stearate and palmitate they contain, and softer when the oleate predominates, and, as regards the alkali present, they are harder when formed with sodium hydroxide, and softer when containing potassium hydroxide. Hence it is that of pure soaps, considered as salts, sodium stearate is the hardest and least soluble, and potassium oleate the softest and most soluble.

Liquid soaps are largely coming into use as economical and sanitary substitutes for soap in public lavatories. Several good formulas have been proposed by E. R. Jones (*J. A. Ph. A.,* 1914, 1537) for use with soft, medium and hard waters, respectively.

Preparation.—The following is an outline of the process for making soap. The oil or fat is boiled with a solution of caustic alkali, beginning with a weak solution, and as saponification proceeds using a stronger lye until the whole forms a thick mass, which can be drawn out into long clear threads. After the soap is completely formed, the next step is to separate it from the excess of alkali, the glycerin, and the redundant water. This is effected by adding common salt, or a very strong alkaline lye, in either of which the soap is insoluble. The same end may be attained by boiling down the solution until the excess of the alkali forms a strong alkaline solution, which acts the same part in separating the soap as the addition of a similar solution. As soon as the soap is completely separated, it rises to the surface, and, when it has ceased to froth in boiling, it is ladled out into wooden frames to congeal, after which it is cut into bars by means of a wire. The soap, as first separated, is called *grain soap.* It may be purified by dissolving it in an alkaline lye and separating it by common salt. During this process the impurities subside, and the soap combines with more water, and hence it becomes weaker, although purer and whiter. If the grain soap be not purified, it will form *marbled soap*—the colored streaks arising principally from an insoluble soap of oxidized iron. Sometimes the marbled appearance is produced by adding to the soap, as soon as it is completely separated, a fresh portion of lye, and immediately afterwards a solution of ferrous sulphate. The greenish-black ferrous hydroxide is precipitated, and gives rise to dark-colored streaks, which, by exposure to the air, become red in consequence of the conversion of the black hydroxide into the ferric hydroxide.

When commercial toilet soap is required, the *grained* soap, or, as it is sometimes called, *boiled* soap, is often remelted, perfumed, and worked over by the process of *milling, plotting,* and *moulding,* whereby the soap is brought into the desired shape for popular use. The *cold process* is also used, and is preferred by many because of its simplicity and economy. The following (from Sadtler's *Industrial Organic Chemistry,* 1906, 64) gives the outlines of the process. The so-called "cold process" requires the use of exact weights of well-refined fats and of caustic soda of a given specific gravity (from 32° to 36° B.), the quantities being such that only just enough soda is present to completely saponify the fat. The materials are allowed to stand together for a short time and then thoroughly mixed in a kettle provided with steam agitating paddles, and kept at a temperature of not over 48.9° C. The reaction proceeds rapidly, and after some fifteen minutes the materials have so far united that they will not separate on standing, although the complete saponification of the charge may require days. They are then run out into the cooling frames. It is obvious that soaps made in this way retain all the glycerin originally combined with the fatty acids disseminated through the particles of soap, and belong to the class of "filled" or "padded" soaps. When cocoanut oil alone is used, the temperature of working in this cold process need not be higher than 23.9° C. in summer and 32.2° C. in winter; if one-half tallow, from 40° to 42.2° C., and if two-thirds tallow, from 45° to 48.9° C. is necessary. A well-refined tallow can be saponified in this way, too, and rosin may be added. For a practical process for making soap in small quantities without boiling, see *U. S. D.,* 19th edition, page 1089.

The official *soap* (*Sapo,* U. S.; *Sapo Durus,* Br.) is an olive oil soda soap, made on the same general plan as that just explained.

Common soap is also a soda soap; but instead of olive oil it is made from various vegetable or animal fats. This soap corresponds with the white soap of northern European countries and of the United States.

Besides the official soaps of the U. S. and Br. Pharmacopœias, there are many other varieties, more or less used for medicinal or economical purposes. *Starkey's soap* is prepared by uniting, by trituration, equal parts of potassium carbonate, oil of turpentine, and Venice turpentine. *Beef marrow soap* is a fine animal oil soap, also included in the French standard. *Windsor soap* is a scented soda soap, made of one part of olive oil and nine parts of tallow. *Eau de luce* (*aqua luciæ*) is a kind of liquid soap, formed by mixing a tincture of oil of amber and balsam of Gilead with ammonia water. *Transparent soap* is prepared by several methods. In one process, glycerin is added which makes a clear transparent mass upon solidification; soap containing glycerin, however, is very hygroscopic. The German transparent soap always contains a large quantity of cocoanut-oil soap. Modern transparent soaps owe their transparency usually to their having been made into an alcoholic solution and then the alcohol carefully recovered, which leaves the mass transparent. Cheap grades of transparent soaps often owe this property to the presence of sugar which communicates the desired property when present to the extent of 5 or 10 per cent. *Marine soaps,* or *hard water soaps,* are soaps which possess the property of lathering freely with hard water. They are usually manufactured from cocoanut oil. *Palm soap* is prepared from sodium hydroxide and palm oil, to which tallow is added to increase its firmness. If it be wanted white, the palm oil may be bleached by heat, potassium dichromate with sulphuric acid, chlorine, or exposure to the sun. This soap has a yellowish color, and the agreeable odor of violets derived from the oil. *Soap balls* are prepared by dissolving soap in a little water and then forming it with starch into a mass of the proper consistence. *Common yellow soap* (*rosin soap*) derives its character from an admixture of rosin with the fats, rosin being saponifiable and yielding a detergent soap. Sodium silicate is largely used as a filler which adds to the detergent properties of the soap. It is too harshly alkaline for use in toilet soaps or soaps intended for anything but the crudest purposes.

Borax soap is soap containing borax as an added detergent ingredient.

Cereals such as cornmeal, oatmeal, etc., are sometimes added to soap for special purposes. Their mechanical presence is sometimes of value, though they are frequently added for cheapening purposes.

Soaps with fancy descriptive names are usually deceptive in their character. *Lemon juice, buttermilk, seaweed,* etc., are only of advertising value as soap constituents.

Floating soaps are those in which minute air bubbles have been incorporated in the soap mass before cooling. This makes the cakes buoyant.

All varieties of soap are now manufactured in the United States. Large amounts of olive oil soaps and very fine toilet soaps are, however, imported from France, Italy, and Spain.

SPECIFICATIONS FOR SOAPS.—The following standards and specifications have been adopted by the U. S. Bureau of Standards for various types of soaps, and have been published in Circular No. 62 of the Department of Commerce, June, 1919. In these specifications matter volatile at 105° C. is considered as moisture although volatile oils, when present as perfumes, are driven off at this temperature. *Milled Toilet Soap.*—Matter volatile at 105° C., not over 15 per cent.; free alkali as sodium hydroxide, not over 0.1 per cent.; alkaline salts as sodium carbonate, not over 0.3 per cent.; sodium sulphate, not over 0.1 per cent.; sodium chloride, not over 0.3 per cent.; material insoluble in water, not over 0.1 per cent.; unsaponifiable matter, not over 0.1 per cent.; rosin, sugar, and other foreign matter must be absent. *White Floating Soap* has the same standards as milled toilet soap, except that the matter volatile at 105° C. may reach 34 per cent. and the alkaline salts 0.5 per cent. *Liquid Soap* must contain not less than 20 per cent. of anhydrous soap, not more than 0.3 per cent. of alkaline salts, not more than 0.3 per cent. of potassium chloride, and no sulphates nor sugar. *Shaving Soap* must meet the following requirements: Matter volatile at 105° C., not over 15 per cent.; free alkali, not over 0.3 per cent.; potassium chloride, not over 0.3 per cent.; matter insoluble in water, not over 0.1 per cent.; unsaponifiable matter, not over 0.1 per cent.; rosin, sugar and other foreign matters must be absent, and at least 50 per cent. of the total alkali must be potash.

The following are the specifications for *salt water soap,* which is a cocoanut oil soap capable of lathering in brine: Matter volatile at 105° C., not over 55 per cent.; free alkali, not over 0.5 per cent.; alkaline salts, as sodium carbonate, not less than 2 per cent. nor more than 3 per cent.; chlorides, not less than 2.5 per cent. nor more than 3.5 per cent.; rosin, sugar, and other foreign matters must be absent. *Special Grade Laundry Soap.*—Matter volatile at 105° C., not over 34 per cent.; free alkali as sodium hydroxide, not over 0.2 per cent.; alkaline salts, not over 1 per cent.; sodium chloride and sulphate, not over 1 per cent.; matter insoluble in water, not over 0.1 per cent.; rosin, not over 15 per cent. *Ordinary Grade Laundry Soap.*—Matter volatile at 105° C., not over 34 per cent.; free alkali as sodium hydroxide, not over 0.5 per cent.; alkaline salts, not less than 2 per cent. nor more than 6 per cent.; sodium chloride, not over 1 per cent.; sodium sulphate, not over 1 per cent.; matter insoluble in water, not over 0.5 per cent.; rosin, not over 25 per cent. *Chip Soap.*—Matter volatile at 105° C., not over 15 per cent.; free alkali as sodium hydroxide, not over 0.5 per cent.; alkaline salts, not over 0.5 per cent.; sodium chloride, not over 0.5 per cent.; matter insoluble in water, not over 0.1 per cent. *Soap Powder.*—Anhydrous soap, not less than 30 per cent. nor more than 35 per cent.; sodium carbonate, not less than 40 per cent. *Hand Grit Soap.*—Matter volatile at 105° C., not over 15 per cent.; free alkali as sodium hydroxide, not over 0.1 per cent.; alkaline salts, not over 0.3 per cent.; insoluble siliceous material, not less than 30 per cent. nor more than 35 per cent.; 98 per cent. of the siliceous material must pass through a sieve having 200 meshes to the linear inch; rosin, sugar, and other foreign matters must be absent. *Scouring Soap A.*—Matter volatile at 105° C., not over 5 per cent.; free alkali as sodium hydroxide, not over 0.1 per cent.; alkaline salts, not over 1 per cent.; insoluble siliceous material, not less than 88 per cent. nor more than 93 per cent.; all of the siliceous material must pass through a sieve having 100 meshes to the linear inch, and at least 95 per cent. must pass through a sieve having 200 meshes to the linear inch, and it must not scratch glass. Rosin, sugar, and other foreign matters must be absent. *Scouring Soap B.*—Matter volatile at 105° C., not over 5 per cent.; free alkali as sodium hydroxide, not over 0.1 per cent.; alkaline salts, not over 3 per cent.; insoluble siliceous material, not less than 75 per cent. nor more than 85 per cent. The insoluble siliceous material should mainly consist of quartz, and it must all pass through a sieve having 100 meshes to the linear inch, and at least 75 per cent. must pass through a sieve having 200 meshes to the linear inch. Rosin, sugar, and other foreign matters must be absent. *Automobile Soap.*—Matter volatile at 105° C., not over 55 per cent.; free alkali as sodium hydroxide, not over 0.05 per cent.; free oleic acid, not over 0.1 per cent.; matter insoluble in water, not over 0.1 per cent.; alkaline salts, not over 0.5 per cent.

Properties.—Soap, whatever may be its variety, has the same general properties. Its aspect and consistence are familiar to every one. Its odor is peculiar, and its taste slightly alkaline. It is usually somewhat heavier than water, and therefore sinks in that liquid. Exposed to heat it quickly fuses, swells up, and is decomposed. It is soluble in water, and more readily in hot than in cold. Acids added to an aqueous solution of soap combine with the alkali, and set free the fatty acids, which, being diffused through the water give it a milky appearance. Its decomposition is also produced by metallic salts, which invariably give rise to insoluble soaps. Soap is soluble in cold and abundantly in boiling alcohol. This solution constitutes the *tincture of soap.* The efficacy of soap as a detergent depends probably in chief part on its power of emulsifying fats, although also in part upon its hydrolytic decomposition when in solution, whereby alkali is liberated which saponifies and emulsifies grease and fatty substances rendering them readily removable in the washing processes. The chief adulterations in soap are lime, silica, gypsum, heavy spar, steatite, pipe-clay, and sodium sulphate. Some of these constituents, however, are normal ingredients of soaps intended for special purposes as for scouring. When adulterated with these substances, it will not be entirely soluble in alcohol.

Description and Physical Properties.—"A white or whitish solid, in the form of bars, hard, yet easily cut when fresh, or a fine, yellowish-white powder. It has a faint, characteristic odor, free from rancidity and a disagreeable, alkaline taste. Soap is soluble in water and in alcohol, more readily, however, with the aid of heat. An aqueous solution of Soap is alkaline to indicators.

"Dissolve about 0.5 Gm. of Soap, accurately weighed, in 10 cc. of alcohol, evaporate the mixture to dryness in a tared beaker containing 1 Gm. of clean sand, which has been previously dried at 110° C., and dry the residue to constant weight at 110° C.: the loss does not exceed 36 per cent for unpowdered Soap or 10 per cent. for powdered Soap (*water*). A solution of a quantity of Soap corresponding to 0.64 Gm. of dried Soap in 25 cc. of hot alcohol does not gelatinize on cooling to 20° C. (*soap from animal fats*). Ten cc. of an aqueous solution of Soap (1 in 20) remains unchanged in color upon the addition of ammonium sulphide T.S., and upon acidulating another portion of 10 cc. of the solution with hydrochloric acid and filtering, the filtrate remains unchanged in color when an equal volume of hydrogen sulphide T.S. is added and the mixture allowed to stand well-stoppered, in a warm place, for half an hour (*heavy metals*). Dissolve about 10 Gm. of Soap, accurately weighed, in 100 cc. of neutralized alcohol, with the aid of heat. Transfer the undissolved residue, if any, to a tared filter which has been dried at 100° C., and wash it thoroughly with boiling neutralized alcohol. The weight of the residue after drying at 100° C. does not exceed 1 per cent. of the weight of dry Soap taken (*sodium chloride, carbonate, silica, or other alcohol-insoluble substances*). This residue, thoroughly washed with distilled water and dried at 100° C., does not yield a residue exceeding 0.15 per cent. of the weight of dry Soap taken (*silica or other water-insoluble substances*). The alcoholic filtrate and washings from the preceding test are not reddened by 3 drops of phenolphthalein T.S. (*sodium hydroxide*). Dissolve about 10 Gm. of Soap in 200 cc. of hot distilled water, add 2 drops of methyl orange T.S. and then diluted sulphuric acid with constant stirring until the aqueous layer becomes red. Boil the mixture until the supernatant layer of the fatty acids is clear and free from solid particles. Separate the aqueous layer with the aid of a siphon and wash the fatty acids by decantation with hot distilled water, until a 10 cc. portion of the washings, acidulated with a drop of hydrochloric acid, no longer gives a precipitate on the addition of barium chloride T.S. Place the dish containing the fatty acids on a water bath and heat until they are completely liquefied, filter the warm acids through a dry filter in a hot-water funnel into a flat dish, and dry over sulphuric acid. The iodine number of the acids thus obtained is not less than 84 and not more than 90.

"Preserve in well-closed containers." *U. S.*

"Greyish-white, yellowish-white, or greenish-white, becoming horny and pulverisable when dried. Nearly inodorous. Soluble in 20 parts of cold *water,* and in 1.5 parts of hot *water;* soluble in *alcohol* (90 per cent.), more readily when warmed. Responds to the tests for alkaline hydroxides and carbonates and for free fatty acids described under 'Sapo Animalis.' Does not impart a greasy stain to white unglazed paper (absence of free oil). Loses not more than 30 per cent. of its weight when dried at 110° C. Ash not deliquescent (absence of potassium soap). The absence of fatty acids derived from oils other than Olive Oil is determined by the following process:—Dissolve the Soap in hot *water,* add a slight excess of *hydrochloric acid* and heat on a water-bath until the liberated fatty acids form a transparent layer. Separate the fatty acids on a wet filter-paper, and wash with hot *water* until the washings are neutral to *solution of methyl orange.* Filter the oily layer through a dry filter-paper in a warm oven. The fatty acids thus separated possess the following characters:—*Iodine value,* 83 to 92; *acid value,* 195 to 205; melting point 21° to 28° C.; *refractive index* at 40° C., 1.4540 to 1.4580." *Br.*

Olive oil soda soap (*Sapo*), otherwise called *Castile* or *Spanish soap,* is a hard soap, and is presented under two principal varieties, the white and the marbled. *White Castile soap,* when good, is of a pale yellowish-white color, incapable of giving an oily stain to paper, devoid of rancid odor or strong alkaline qualities, and entirely soluble both in water and in alcohol. It should not feel greasy, nor grow moist, but, on the contrary, should become dry by exposure to the air, without exhibiting any saline efflorescence. This variety of soap contains about 21 per cent. of water. Sometimes it contains a larger proportion of water, with which the soap is made to combine by the manufacturer, with the fraudulent intention of increasing its weight. Soap thus adulterated is known by its unusual whiteness, and by its suffering a great loss of weight in a dry air. *Marbled Castile soap* is harder, more alkaline, and more constant in its composition than the other variety. It contains about 14 per cent. of water. Having less water than the white Castile, it is a stronger and more economical soap, but at the same time is less pure. The impurity arises from the veins of marbling, consisting of ferruginous matters, as already explained, and from various substances added as make-weights.

Soap bubbles have played an important part in the investigations of the subject of surface tension. Sir James Dewar has kept soap bubbles intact for more than a year in an atmosphere free from foreign particles or vibrations.

Soap is an emulsifying agent of peculiar value in certain cases. Scoville has prepared a stiff jelly-like emulsion of olive oil containing 97 per cent. of oil and only 0.15 Gm. of sodium oleate. (*Bull. Pharm.*, 1915, 141.)

The emulsifying action of soap, in connection with its detergent qualities, is due to the hydrolytic effect of water and the colloidal dispersion of the fatty acids.

A *soap substitute* for detergent purposes, which in some respects is superior to soap as a cleansing agent has been proposed by Schneider (*D. C.*, 1916, lx, 407). It is made as follows: One hundred grammes of soap bark are heated on a water-bath for a half hour with 300 grammes of water, the mixture strained, the liquid mixed with 400 grammes of kaolin and 400 grammes of powdered talcum, and the resulting paste perfumed with any suitable substance. The paste does not froth, but cleanses the hands, it is said, better than ordinary soap.

Incompatibles.—Soap is decomposed by all the acids, earths, and earthy and metallic salts. Acids combine with the alkali, and set free the fatty acids of the soap; the earths unite with the fatty acids, and separate the alkali, while the earthy and metallic salts give rise, by double decomposition, to an insoluble soap of their base and a saline combination between their acid and the alkali of the soap. Hard waters, in consequence of their containing salts of lime, decompose and curdle soap. They may be rendered soft, and fit for washing, by adding alkali carbonates, hydroxides or borates.

Uses.—Soap is laxative and antacid. It acts like an alkaline base and was formerly used to some extent internally, but has been entirely superseded by more elegant alkaline compounds, except in laxative preparations. In *constipation,* particularly when arising from hardened feces in the rectum, a strong solution of soap, especially of soft soap, forms a useful enema. When the latter is used, two tablespoonfuls may be dissolved in a pint of warm water. Externally soap is used in various *skin diseases,* not merely for its detergent effect, but also to soften the horny layer of the epiderm. Soap has a distinct if not very powerful antiseptic action. According to Hamilton (*J. I. E. C.,* 1911, iii, 582), it is practically impossible to get a strong enough solution of a hard neutral soap to exercise any distinct germicidal effect, but if free alkali be present it is much more active. Davis and Swartz (*J. A. M. A.,* December 11, 1921, lxxvii) find that sodium oleate has a definite value against the gonococcus. Attempts have been made to increase the germicidal value of soap by the addition of various disinfecting agents, especially cresol and mercuric iodide. The practical value of these soaps, however, is open to question; Wildman (*Ph. Era,* 1919, lii, p. 123) after bacteriological tests came to the conclusion that although the mercuric iodide soap had a distinct disinfectant action, for practical purposes the tincture of green soap had a greater sterilizing effect upon the hands.

In pharmacy, soap is frequently employed for the purpose of giving a proper consistence to pills; but care must be taken not to associate it with a substance which may be decomposed by it. It is an excellent emulsifying agent when the mixture is intended for external use. It is also an ingredient in some liniments and plasters. In toxicology it is used as a chemical antidote for the mineral acids and the caustic salts of iron, and should always be resorted to in poisoning by these agents, without a moment's delay, and its use continued until magnesia, chalk, or sodium or potassium bicarbonate can be obtained. The mode of administration, in these cases, is to give a teacupful of a strong solution of soap every three or four minutes, until the patient has taken as much as he can swallow.

Dose, five grains to half a drachm (0.32–2.0 Gm.), given in pill.

Off. Prep.—Emplastrum Saponis, *Br., N. F.;* Linimentum Saponis, *U. S., Br.;* Linimentum Chloroformi (from Soap Liniment), *U. S.;* Pilulæ Aloes, *U. S.;* Pilulæ Aloes et Asafetidæ, *N. F.;* Dentifricium, *N. F.;* Lavatio Ori, *N. F.*

SAPO ANIMALIS. Br.

CURD SOAP

"Curd Soap is soap made from sodium hydroxide and purified animal fats consisting principally of stearin; it contains not more than 30 per cent. of water." *Br.*

Sapo sebacinus; Sapo domesticus; Sapo Vulgaris; Animal Soap, Tallow Soap, Stearin Soap; Savon animal, *Fr.;* Hausseife, Talgseife, Stearinseife, *G.;* Sapone animale, *It.;* Jabon animal, *Sp.*

The British Pharmacopœia, 1914, has retained curd soap in its list, and thus describes it: "Yellowish-white or greyish-white; nearly inodorous; easily moulded when heated, becoming horny and pulverisable when dried. Sparingly soluble in cold *water;* completely soluble in hot *water;* soluble in *alcohol* (90 per cent.). When 5 grammes of the dried and powdered Soap are dissolved in 50 millilitres of boiling *alcohol* (90 per cent.), and the solution filtered while hot, the filter being thoroughly washed with more of the boiling *alcohol,* the filtrate is neutral to *solution of phenolphthalein* (absence of alkaline hydroxides and free fatty acids), and if the filter is then washed with hot *water,* the washings require for neutralisation not more than 5 millilitres of *N/10 solution of sulphuric acid, solution of methyl orange* being used as indicator (limit of alkaline carbonates). Does not impart a greasy stain to white unglazed paper (absence of free fats). Loses not more than 30 per cent. of its weight when dried at 110° C. Ash not deliquescent (absence of potassium soap)." *Br.*

Soap made from animal oils and fats is very largely used for all domestic purposes; it was long used for making *solid opodeldoc,* but is now replaced by sodium stearate. (See *Linimentum Saponato-Camphoratum,* N. F., Part III.)

Off. Prep.—Linimentum Potassii Iodidi cum Sapone, *Br.*

SAPO MOLLIS. U. S., Br.

SOFT SOAP Sapo Moll. [Green Soap]

"Soft Soap is soap made from potassium hydroxide and olive oil." *Br.*

Sapo Viridis, *U. S. P.* 1880; Savon Noir, Savon mou, *Fr.;* Sapo Kalinus, *P. G.;* Kaliseife, Schmierseife, *G.;* Sapone di potassa, *It.*

"Linseed Oil, 400 Gm.; Dekanormal Solution of Potassium Hydroxide, 29 cc.; Dekanormal Solution of Sodium Hydroxide, 110 cc.; Glycerin, 50 cc.; Water, a sufficient quantity, to make 1000 Gm. Mix the dekanormal solutions, pages and , with the oil and enough water to make the product weigh 925 Gm. Heat the mixture to boiling with frequent stirring, add the glycerin and continue the boiling until the mixture becomes transparent and a portion dissolves completely in hot water, producing a clear solution. Then add sufficient hot water to make the Soap weigh 1000 Gm. and allow to stand with little stirring until the water is absorbed.

"NOTE.—The 29 cc. of dekanormal solution of potassium hydroxide directed above may be replaced by 19.14 Gm. of 85 per cent. potassium hydroxide and the 110 cc. of dekanormal solution of sodium hydroxide may be replaced by 48.89 Gm. of 90 per cent. sodium hydroxide, dissolving the hydroxides in 100 cc. of water. If upon assay the potassium and the sodium hydroxides are found to be of any other strength, a proportionately larger or smaller quantity should be taken." *U. S.*

For more than one hundred years, under the name of *"green soap,"* there has been used in Europe a soap made by saponifying linseed, rape seed, or other vegetable oils with various refuse oils, usually including fish oils, an excess of potassium hydroxide, and a little sodium hydroxide. The green color of this soap was probably due to the presence of chlorophyll in the impure vegetable oils used. This green soap, or so-called "German soap," was formerly imported into America, but at present has been almost entirely superseded by soft soap made in this country, from which it does not differ in the nature of its active constituents or in its therapeutic properties.

Both the British and U. S. Pharmacopœias differ with the common practice and with each other in the formulas for soft soap. The Br. has for many years employed olive oil. The U. S., 1890 and VIII employed linseed oil, but in the 9th Revision experiment was made of using cottonseed oil. This, however, not proving satisfactory, the present U. S. has returned to linseed.

If a green soap be wanted, it may be made by the process given in the *U. S. D.,* 19th edition, p. 1093. The soft soap of France, formerly the *savon vert* of the French Codex, has a greenish color, and usually the consistence of a soft ointment. It is made of hemp seed oil, or sometimes of the dregs of olive oil, and potassium hydroxide. G. M. Beringer (*Proc. A. Ph. A.,* 1903, 420) prefers to use Malaga olive oil in making green soap, and M. I. Wilbert (*Proc. A. Ph. A.,* 1904, 228) extracts the green coloring matter from hemp seed by macerating 25 parts of ground hemp seed with alcohol and obtains 100 parts of a tincture; by substituting an equal measure of this tincture for the quantity of alcohol used in the official process, a green soap can be made, which will have the color which is regarded by some as a very important characteristic.

Description and Physical Properties.—"A soft, unctuous, yellowish-white to brownish-yellow mass, having a slight, characteristic odor and an alkaline taste. An aqueous solution of Soft Soap is alkaline to litmus paper and phenolphthalein T.S.

"Dissolve about 5 Gm. of Soft Soap, accurately weighed, in 100 cc. of hot neutralized alcohol, collect the residue, if any, on a filter, thoroughly wash it with hot neutralized alcohol, and dry it to constant weight at 100° C. The weight of the residue does not exceed 3 per cent. of the weight of Soap taken. The combined filtrate and washings, on the addition of 0.5 cc. of phenolphthalein T.S. and titration with tenth-normal sulphuric acid, shows not less than 0.1 per cent. and not more than 0.25 per cent of KOH. Each cc. of tenth-normal sulphuric acid corresponds to 0.00561 Gm. of KOH. A solution of Soft Soap in hot distilled water (1 in 20) is nearly clear. Soft Soap loses not more than 52 per cent. in weight when tested for water as directed under *Sapo.*" *U. S.*

"Yellowish-white to green; of an unctuous consistence. Nearly inodorous. Readily soluble in *alcohol* (90 per cent.), leaving not more than 3 per cent. of insoluble residue. Responds to the tests for alkaline hydroxides and carbonates and for free fatty acids described under 'Sapo Animalis.' Does not impart a greasy stain to white unglazed paper (absence of free oil). Ash very deliquescent, and yields no characteristic *reactions* for copper. The mixed fatty acids, liberated and treated as described under 'Sapo Durus,' possess the characters there specified." *Br.*

Uses.—Soft soap possesses not only the detergent properties of neutral soaps, but because of the excess of alkali has active medical virtues, especially as a topical remedy. In the first place it removes the fat more thoroughly from the skin and is therefore of service in those forms of *skin diseases* accompanied with disturbances of sebaceous secretion, such as *seborrhea* or *comedo.* It has also the property of softening the keratin elements of the epiderm, and is therefore useful in conditions accompanied with crusts and scales, such as *psoriasis* and *chronic eczema.* Because of its local irritating action it may also be used as a stimulant in *acne vulgaris* and *rosacea.* It is also asserted to be of adjuvant service in the treatment of various parasitic skin diseases.

Kappesser (*Fort. Med.,* 1912) has reported favorable results from the use of inunctions of one-half to one drachm (2–3.9 Gm.) of soft soap in *scrofulous lymphadenitis.* Kuelbes (*Th. M.,* 1914, xxviii) has found it of occasional benefit also in a large variety of other conditions, especially *cardiac neuroses* and *migraine.* In *chronic bronchitis* and *dyspepsia* he asserts the inunctions often improve the general condition of the patient, but in *asthma* they usually were without influence.

SAPPAN. Br.

SAPPAN

"Sappan is the heart-wood of Cæsalpinia Sappan, *Linn.*" *Br.*

Sappan wood, Sampfen wood, Bakam, Tairi, Patang, Teri, Verzino, *It.;* False Sandalwood, Indian Redwood, Samfen.

Cæsalpinia Sappan is a small thorny tree indigenous to the Eastern and Western Asiatic Peninsulas, Pegu and Tenasserim, and is also cultivated in Central India. The leaves are large and abruptly bi-pinnate; the flowers being yellow and in axillary racemes; and the pods are oblong, flattened, nearly smooth and dehiscent or indehiscent. The wood yields a valuable red dye which is also prepared from the pods and from the bark. The commercial samples vary considerably. There are two commercial varieties, viz., (1) Singapore or Dhansari, and (2) Ceylon sappan, the former being preferred. According to Dymock, the freshly cut wood is whitish, but becomes red on exposure to the air. He also states that the addition of alkalies increases the yield of coloring matter, turning it a reddish-violet.

According to the British Pharmacopœia, it occurs in "hard, heavy pieces of variable size, or in orange-red chips. In transverse section, well-marked concentric rings, numerous narrow medullary rays, and large vessels. No odor; taste slightly astringent. It communicates to *alcohol* (90 per cent.) and to *water* a red color, which becomes carmine-red, but not purple, upon the addition of *solution of sodium hydroxide* (distinction from Logwood)." *Br.*

According to the investigations of Bolley, sappan wood contains *brasilin,* $C_{16}H_{14}O_5$, identical with that of Brazil wood. (See Part II.)

Sappan, as it is sometimes called, has been an article of commerce for at least five hundred years. It is employed in the arts as a substitute for logwood in dyeing. Medicinally it is used as an astringent in the treatment of *diarrhea.* It may be given in the form of a decoction.

Dose, from fifteen to forty-five grains (1–3 Gm.).

Off. Prep.—Decoctum Sappan, *Br.*

SARSAPARILLA. U. S.

SARSAPARILLA Sarsap.

"Sarsaparilla is the dried root of *Smilax medica* Chamisso and Schlechtendal, known in commerce as Mexican Sarsaparilla; or of *Smilax officinalis* Kunth, or of an undetermined species of *Smilax* known in commerce as Honduras Sarsaparilla; or of *Smilax ornata* Hooker filius known in commerce as Central American or Jamaica Sarsaparilla (Fam. *Liliaceæ*). Sarsaparilla contains not more than 2 per cent. of foreign organic matter, excepting the rhizome and crown portion, which must be removed before the root is ground and powdered. Mexican Sarsaparilla yields not more than 4 per cent. of acid-insoluble ash. The other official varieties conform to the standards for acid-insoluble ash under Vegetable Drugs." *U. S.*

Sarsæ Radix, *Br.,* 1898; Jamaica Sarsaparilla; Salsepareille du Mexique, *Fr.;* Radix Sarsaparillæ, *P. G.;* Sarsaparille, Sarsaparilla, *G.;* Salsapariglia, *It.;* Zarzaparrilla (Raiz de), *Sp.*

The plants comprising the genus *Smilax* are climbing or trailing vines or shrubs, with a pair of tendrils arising as modified stipules from the bases of their petioles, 3- to 7-nerved and strongly reticulate leaf blades and prickly stems. The last mentioned character is expressed in the name of the drug, which is derived from two Spanish words (*zarza* and *parilla*), signifying a small, thorny vine.

The official sarsaparilla-yielding plants are all climbing evergreen shrubs with prickly stems, alternate, coriaceous leaves which vary from cordate, cordate-ovate, auriculo-hastate to ovate-oblong in outline, small flowers, arranged in axillary umbels, and berry fruits. They are indigenous to Mexico, Central America, and the warm latitudes of South America. The roots are very long and slender, and originate in great numbers from a common head or rhizome, from which the stems of the plant rise. The whole root with the rhizome is usually dug up, and as brought into market exhibits not unfrequently portions of the stems attached, sometimes several inches in length. The commercial sarsaparillas are conveniently divided into the mealy and non-mealy sarsaparillas. The first class comprises especially the Honduras, Guatemala, and Brazilian varieties; the second the Jamaica, Mexican and Guayaquil sarsaparillas. A very convenient key for distinguishing the commercial sarsaparillas by certain anatomical characters has been devised by Luerssen in his *Handbuch der Medicinpharm. Botanik*, ii, 404.

Smilax medica yields the variety known commercially as *Mexican, Vera Cruz, Tampico* or *Gray Sarsaparilla.* It occurs as clusters of long roots attached to a knotty crown (portion of the rhizome) or as rootlets deprived of the crown. These are packed, commonly, in large, rather loose bales weighing about 200 pounds. The roots are grayish-brown to dark brown, nearly devoid of fibrous rootlets and possess deep furrows to which a blackish earth frequently adheres. Histologically, they are characterized by their hypodermal and endodermal cells. The former show their outer and radial walls more thickened than the inner walls while the latter show the inner and radial walls more thickened than the outer walls. Mexican sarsaparilla is imported from Vera Cruz and Mexico City.

Smilax officinalis or an undetermined species of *Smilax* yields the commercial variety known as *Honduras* or *Brown Sarsaparilla.* It occurs in cylindrical bundles from 2 to 3 feet in length which are composed of long roots folded lengthwise. Each bundle is closely tied around with a long root usually of the same plant. The roots are externally of a reddish-brown or dark brown color and show occasional fibrous rootlets. Histologically they are characterized by their uniformly thickened hypodermal and endodermal cells. This variety is imported from Honduras in serons containing a number of bundles.

Smilax ornata yields the commercial variety known as Jamaica, Costa Rica or Red Sarsaparilla. It is collected in Central America, especially in Costa Rica, and it owes its name to the fact that it has been largely exported to London through the island of Jamaica. It is the most highly prized variety used in Great Britain. As found in commerce it is in rolls from twelve to eighteen inches long by four or five in thickness, composed exclusively of long slender many-radicled roots very loosely held together by a few turns. Sometimes it is pressed into large bales. It is further to be distinguished from Honduras sarsaparilla by its dark color, the greater abundance of coarse rootlets, the less quantity of starch, its relatively thick cortex, and its less sharp taste. Externally it is also redder than is commonly the case with Honduras sarsaparilla. Kobert (*P. J.*, 1912, lxxxviii, p. 779) has found that the *S. ornata* has only one-eighth of the hemolytic power of the Vera Cruz sarsaparilla, which he takes as a test of its saponin content. He believes the plant is unfit for medical use.

Cultivated Jamaica Sarsaparilla (*Roja Inglesa*) occurs in thick short rolls and is especially characterized by its yellow-brown or orange color. According to W. B. Hemsley, Hooker's I. P. pl. 2589, it is the product of *S. utilis* Hemsley, a species related to *S. ornata*, from which it differs by its long pediculated simple umbels.

Several other varieties of sarsaparilla occasionally occur on the world's markets, the most important of which are Guayaquil and Lima sarsaparillas.

Guayaquil Sarsaparilla, according to Spruce grows in valleys on the western slopes of the equatorial Andes. It is usually imported in rectangular shaped bales which contain a number of flattened bundles of rhizomes and roots, or roots only. The rhizome and a portion of the stem are often present, the latter being round and prickly. The root is mahogany brown, large, and coarse-looking, with a good deal of fiber. The bark is furrowed, rather thick, and not mealy in the slenderer portions of the root, which is near the rootstalk; but, as the root becomes stout, so its bark becomes smoother, thicker, and amylaceous, exhibiting when cut a fawn-colored or pale yellow interior. It is thought to be yielded by a variety of *S. papyracea.*

Lima or *Lima Jamaica Sarsaparilla* comes from Panama. It bears a close resemblance to Jamaica sarsaparilla but occurs in longer bundles and is packed in layer bales.

Carácas Sarsaparilla was formerly brought in large quantities from La Guayra but is now off the market.

Brazilian, Para or *Lisbon Sarsaparilla* which formerly came from Para, Brazil, has practically disappeared from North America and European commerce but is said to be still used in South American countries. It occurred in cylindrical bundles from three to five feet in length by about a foot in thickness, bound about by close circular turns of a very flexible stem, and consisting of unfolded roots, destitute of caudex (rhizome) and stems, and having a few radical fibers. It is distinguished by the thinness of its cortex, the large amount of starch that it contains and its large, radially elongated endodermal cells.

The rhizome of *Smilax China,* a native of China and Japan, has been employed under the name of *China Root* for similar purposes with the official sarsaparilla. As it occurs in commerce, it is in pieces from three to eight inches long and an inch or two thick, usually somewhat flattened, more or less knotty, often branched, of a brownish or grayish-brown color externally, whitish or of a light flesh-color internally, without odor, and of a taste flat at first, but afterwards very slightly bitterish and somewhat acrid, like that of sarsaparilla. The root of *Smilax aspera* is said to be employed in the south of Europe as a substitute for sarsaparilla; but it has little reputation. The East India sarsaparilla, which was at one time referred to this species of smilax, is the product of *Hemidesmus indicus*. (See *Hemidesmus.*)

The chief adulterants of Sarsaparilla roots have been aerial stems of similar plants, excessive rhizomes, roots of various species of *Philodendron* and rhizomes of *Pteris* species.

Description and Physical Properties.—"Sarsaparilla is nearly odorless; taste mucilaginous, somewhat sweetish and acrid.

"*Unground Mexican Sarsaparilla.*—Long roots from 3.5 to 6 mm. in diameter, frequently attached to a crown having one or more stout stems; usually shrunken, forming sharp longitudinal ridges and broad furrows; externally light grayish-brown to dark brown; the furrows may contain more or less blackish earth; finely hairy; nearly devoid of branches or fibrous rootlets; fracture of cortex brittle, of central cylinder tough and fibrous; cortex mealy and whitish or brownish and horny; woody zone yellow and porous; pith whitish and distinct.

"*Unground Honduras Sarsaparilla.*—Long roots from 2 to 5 mm., rarely 6 mm. in diameter and bound together by roots of the same plant into compact cylindrical bundles from 8 to 15 cm. in diameter; externally reddish-brown or dark brown, longitudinally wrinkled or finely furrowed with occasional fibrous rootlets; fracture short, sometimes tough and fibrous in the central cylinder; internally a reddish-brown, dark brown, or occasionally light gray cortex, a light yellow and porous woody zone and a whitish pith.

"*Unground Central American Sarsaparilla.*—Roots long, from 1 to 4, rarely 5 mm. in diameter; externally light brown or reddish-brown, longitudinally wrinkled, occasionally nearly smooth, rarely furrowed and bearing numerous coarse fibrous rootlets; fracture short or tough and fibrous in the central cylinder; internally a white or dark brown cortex, a yellow, porous woody zone and a yellow or white pith.

"*Structure.*—An epidermal layer with basal portions of root hairs; a hypodermis of several layers of strongly lignified cells, the walls being uniformly thickened, except in Mexican Sarsaparilla in which the inner walls are only slightly thickened; a cortex composed of parenchyma cells mostly containing starch, some containing resin or raphides of calcium oxalate, and an endodermis of a single layer of strongly lignified cells, the walls being uniformly thickened except in Mexican Sarsaparilla in which the outer walls are only slightly thickened; a central cylinder composed of a many-rayed vascular bundle and a pith of starch-bearing parenchyma cells; tracheæ large, oval in transverse section and the phloem in small groups near the periphery of the bundle.

"*Powdered Sarsaparilla.*—Light grayish-brown to dark grayish-brown; starch grains numerous, single or compound, the individual grains from 0.003 to 0.023 mm. in diameter, spherical, or biconvex or spherical-tetrahedral and frequently with a central elliptical cleft; calcium oxalate in raphides occurring singly or in groups up to 0.15 mm. in length; cells of the hypodermis and endodermis with lemon-yellow or reddish-yellow porous walls and in Mexican sarsaparilla showing an uneven or irregular thickening, the cells being from 0.08 to 0.50 mm. in length; fragments of tracheæ with simple and bordered pores or scalariform or reticulate thickenings, associated with fibers having rather thin, very slightly lignified and porous walls." *U. S.*

According to Tunmann (*Apoth. Zeit.*, xxv, p. 475), the consumption of sarsaparilla in Europe has decreased materially, and the chief market for this drug at the present time appears to be the United States. While the U. S. Pharmacopœia recognizes three commercial varieties, most of the drug which is used is the Mexican variety, a relatively small quantity of Honduras sarsaparilla being imported. The *Red Jamaica, Orange* or *Native Jamaica* varieties are used chiefly in England. Hartwich has pointed out that the varieties of sarsaparilla on the market are more numerous than are generally supposed. He also states that the greatest emphasis should be placed on the structural characteristics in order to distinguish the several varieties, rather than the form of packing and the supposed botanical origin. He has contributed numerous papers on the subject. (*S. W. P.*, 1897, 1898 and 1909; *A. Pharm.*, 1902; *B. P. G.*, 1907.) Rusby reports finding lots of Mexican sarsaparilla which consisted entirely of "butts" or rhizomes. (*Proc. A. Ph. A.*, 1908, lvi, p. 773.) Kraemer reports finding nineteen ounces of dirt in a bundle of Mexican sarsaparilla weighing four and a half pounds. (*Proc. A. Ph. A.*, 1906, liv, p. 345.) Rusby has reported the presence of a thick, blackish, woody and decidedly astringent root in several shipments of Vera Cruz sarsaparilla. (*J. A. Ph. A.*, 1913, p. 1104.)

Sarsaparilla is efficient in proportion as it is acrid to the taste, which is said by some authors to be confined to the cortical portion, while the ligneous fiber and medullary matter are insipid and inert. Hancock avers that all parts are equally acrid and efficacious. The truth is probably between the two extremes, and, as in most medicinal roots it must be admitted that the bark is more powerful than the interior portions, while these are not wholly inactive.

Constituents.—The most important principles in sarsaparilla are three glucosidal saponins: *smila-saponin*, $C_{20}H_{32}O_{10}$, *sarsa-saponin*, $C_{22}H_{36}O_{10}$, and *parillin*, $C_{26}H_{44}O_{10}$. These principles have been given various names by different chemists, thus smila-saponin has been known as *smilacin* and *sarsaparill-saponin*, and parillin has been known as *pariglin, parillinic acid* and *salseparin*. When the sugar radical is split off by hydrolysis, they yield products which are at least isomeric, and probably identical, and known as *sarsasapogenin* or *parigenin* ($C_{28}H_{46}O_4$). Because of the uncertainty of the botanical material with which many of the chemical investigations have been made, it is impossible to state definitely which of these glucosides occur in each of the plants known commercially as sarsaparilla, but it is probable that the varieties of this drug differ in their composition. Power and Salway (*Tr. Chem. Soc.*, 1914, cv, p. 201) found in the Jamaica sarsaparilla only one of these, sarsaponin, and are inclined to doubt the separateness of smilacin. They also found a new dicarboxylic acid, *sarsapic acid*, $C_6H_4O_6$.

For further details on chemistry, see Schulz (*P. J.*, 1892, p. 6), Kobert (*A. J. P.*, 1892, p. 465), and Apt (*B. P. G.*, 1921, xxxi, p. 155).

The sarsaparilla of commerce is apt to be nearly if not quite inert, either from age, or from having been obtained from inferior species of Smilax. This inequality of the medicine, with the improper modes of preparing it long in vogue, has probably contributed to its variable reputation. The only criterion of good sarsaparilla to be relied on is the taste. If it leave a decidedly acrid impression in the mouth after having been chewed for a short time, it may be considered efficient; if otherwise, it is probably inert. Various false sarsaparillas have been sent into commerce from South America. For description by C. Hartwich see *A. Pharm.*, July, 1902.

Uses.—The use of sarsaparilla in medicine is an interesting example of the power of superstition to survive the attacks of truth and reason. It was introduced into Europe about the middle of the 16th century as a remedy for *syphilis*, but soon fell into disrepute until revived by Fordyce in 1757. Subsequently it came to be used as an alterative in various other chronic diseases, especially *chronic rheumatism* and *scrofula*. There is, however, no reason to believe that it possesses any virtues except as a mild gastric irritant through its saponin content. Its most popular employment is in the form of its compound syrup which is used as a vehicle especially for mercury and potassium iodide.

Sarsaparilla may be administered in the form of infusion, compound decoction, compound syrup, or fluidextract. A beer made by fermenting an infusion of the drug with molasses is said to be a popular remedy in South America. The smoke of sarsaparilla has been recommended in *asthma*. (*J. P. C.*, xviii, 221.)

Dose, thirty to sixty grains (2–3.9 Gm.).

SASSAFRAS. N. F.

SASSAFRAS Sassaf.

"Sassafras is the dried bark of the root of *Sassafras variifolium* (Salisbury) O. Kuntz (Fam. *Lauraceæ*). Sassafras contains not more than 4 per cent. of adhering wood, outer corky tissues or other foreign organic matter and yields not more than 5 per cent. of acid-insoluble ash." *N. F.*

Sassafras Radix; *Br.*; Sassafras Bark, Sassafrax; Radix Sassafras; Cortex Sassafras; Lignum Sassafras, *P. G.*; Sassafras, Fenchelholz, *G.*; Sassafrasso, *It.*; Sasafras (Leño de), *Sp.*

Sassafras is an indigenous tree, of medium size, rising in favorable situations to a height of 35 feet. The bark of the stem and large branches is rough, deeply furrowed, and grayish; that of the extreme branches of twigs is smooth and beautifully green. The leaves, which are alternate, petiolate, and downy when young, vary much in their form and size even upon the same tree. Some are oval and entire, others have a lobe on one side, but the greater number are three-lobed. The flowers, which appear before the leaves, are small, of a pale greenish-yellow color, and disposed in racemes which arise from the branches below the leaves and have linear bracts at their base. The fruit is an oval drupe, about as large as a pea, of a deep blue color when ripe, and supported on a red pedicel, enlarged at the extremity into a cup for its reception. For the microscopical character of the root and bark, see E. S. Bastin, *A. J. P.*, June, 1895. See also *Ph. Rev.*, 1899, 450.

The sassafras is common throughout the eastern United States, extending west into Kansas and south into Mexico. The fresh flowers have a slightly fragrant odor, and almost all parts of the plant are more or less aromatic. The bark of the root is gathered in early spring and autumn, deprived of the outer cork and dried. The commercial supplies are obtained from Mississippi and North Carolina.

The living root-bark is nearly white, but becomes colored, on exposure, immediately after collection.

Description and Physical Properties.—"*Unground Sassafras.*—In irregular, transversely curved or quilled pieces, from 1 to 15 cm. in length and from 1 to 4 mm. in thickness; outer surface orange-brown, nearly smooth and marked with more or less irregular ridges; inner surface light to dark reddish brown, obscurely short-striate; fracture short with a thin reddish brown corky layer and a yellowish white inner bark. Odor aromatic; taste slightly mucilaginous, astringent, aromatic and somewhat pungent.

"*Powdered Sassafras.*—Light reddish brown; exhibits numerous starch grains either single or 2- to 4-compound, the individual grains being more or less spherical or polygonal and frequently with a distinct cleft, from 0.003 to 0.020 mm. in diameter, some of the swollen or altered grains attaining a diameter of 0.030 mm.; characteristic bast-fibers, spindle-shaped, occasionally very irregular in outline, with sharply pointed ends, from 0.150 to 0.400 mm. in length, about 0.025 mm. in diameter, and with very thick, strongly lignified walls, the lumina being frequently nearly obliterated; parenchyma cells containing either starch grains or irregular yellowish red masses of tannin and becoming bluish black upon the addition of ferric chloride T.S.; fragments of wood few, with large, thin-walled tracheæ marked by simple pores and associated with rather thin-walled wood-fibers." *N. F.*

According to Reinsch, the bark contains a heavy and light volatile oil, camphorous matter, fatty matter, resin, wax, a peculiar decomposition product of tannic acid called *sassafrid,* tannic acid, gum, albumen, starch, lignin, and salts. (See *Oleum Sassafras.*) The sassafrid bears some analogy to cinchonic red, and, like it, appears to be a derivative of the tannin, which exists in much larger proportion in the fresh bark than in that long kept. (Procter, *A. J. P.,* 1866, p. 490.)

Uses.—Sassafras owes whatever therapeutic virtue it possesses to its volatile oil. The hot infusion of the bark is a popular domestic remedy as a sudorific for *colds* and also attributed in the popular superstition with peculiar alterative virtues.

Off. Prep.—Fluidextractum Sarsaparillæ Compositum, *N. F.;* Syrupus Pini Albæ Compositus, *N. F.;* Syrupus Pini Albæ Compositus Cum Morphina, *N. F.*

SASSAFRAS MEDULLA. N. F.

SASSAFRAS PITH Sassaf. Med.

"Sassafras Pith is the dried pith of *Sassafras variifolium* (Salisbury), O. Kuntz (Fam. *Lauraceæ*). Sassafras Pith contains not more than 1 per cent. of foreign organic matter and yields not more than 0.5 per cent. of acid-insoluble ash." *N. F.*

Description and Physical Properties.—"In sub-cylindrical, often curved or coiled pieces, from 2 to 10 cm. in length and from 2 to 5 mm. in diameter; very light in weight, externally whitish, occasionally with small fragments of adhering wood; fracture short. Odor slight, sassafras-like; taste mucilaginous.

"*Structure.*—Sections mounted in phloroglucinol T.S. and hydrochloric acid, show nearly isodiametric cells with large intercellular spaces, the walls being more or less lignified and provided with numerous, simple pores; mounts made in water show the separation of a thin layer of mucilage from the inner walls of the cells characterized by the gradual disappearance of the pores.

"Macerate 0.5 Gm. of Sassafras Pith with 25 cc. of cold distilled water for several hours and filter it through purified cotton; a mucilaginous solution is obtained which does not give a precipitate upon the addition of an equal volume of alcohol; if an excess of alcohol is added precipitation takes place." *N. F.*

Sassafras pith should be collected after frost in autumn.

It abounds in a gummy matter, which it readily imparts to water, forming a limpid mucilage, which is not precipitated by alcohol, but has much less tenacity than that of gum arabic and will not answer as a substitute in the suspension of insoluble substances. J. C. and B. L. DeG. Peacock (*Proc. Penna. Ph. A.,* 1917, p. 171) report an investigation of several methods of preparing mucilage of sassafras pith in which the conclusion was reached that maceration of 3 Gm. of sassafras pith with 150 cc. of cold sterile water for ten minutes and subsequent filtration through a pledget of moistened cotton yielded a mucilage superior in characters and keeping quality to that made in any other manner.

Uses.—This mucilage is much employed as a soothing application in inflammation of the eyes, and forms an agreeable and useful drink in *dysenteric, catarrhal,* and *nephritic diseases.* It may be prepared by adding a drachm of the pith to a pint of boiling water.

SCAMMONIÆ RADIX. Br.

SCAMMONY ROOT Scam. Rad.

"Scammony Root is the dried root of Convolvulus Scammonia, *Linn.*" *Br.*

Radix Scammiæ; Levant Scammony; Aleppo Scammony; Scammonée d'Alep, *Fr.;* Scammonium, *Fr. Cod.;* Escaminœa, *Sp.*

Scammony root has been replaced in the U. S. by Ipomœa, but in the Br. is still official, although the substitution of Ipomœa is permitted in the preparation of the resin.

The true scammony is a twining perennial herb indigenous to the region around the eastern end of the Mediterranean, especially Syria.

Scammony root is officially described as: "Brownish-grey or yellowish-grey, tapering or nearly cylindrical, varying usually from two to eight centimetres, or more, in diameter. Frequently contorted and longitudinally furrowed; enlarged at the crown, and bearing the remains of slender aerial stems. Fracture very coarsely fibrous; internally light or dark grey. In transverse section, numerous rounded wood-bundles distributed throughout a paler ground-tissue in which dark resin cells can be distinguished with a lens; in the parenchymatous tissue abundant, characteristic starch grains. Characteristic odor; taste at first somewhat sweet, afterwards slightly acrid. Yields to *alcohol* (90 per cent.)

a resin which has the properties described under 'Scammoniæ Resina.'" *Br.*

The wood consists of compressed pale brown, coarsely porous, usually subdivided fibers in a parenchymatous tissue similar to the bark.

"Under the microscope, sections of Scammony Root show a corky layer consisting of from 2 to 10 rows of cells with thin, yellowish-brown lignified walls; an outer cortex with numerous stone cells occurring singly or in small groups, the walls being moderately thick, porous and not strongly lignified; parenchyma with numerous starch grains and monoclinic prisms of calcium oxalate; fibro-vascular bundles numerous, circular or elliptical with a well developed wood consisting of large tracheæ surrounded by slightly lignified wood-fibers; phloem or sieve prominent in which are included large resin ducts; the parenchyma, both in and surrounding the bundles more or less collapsed and containing either starch or calcium oxalate crystals. The powder is light grayish-brown; when examined under the microscope it exhibits starch grains from 0.003 to 0.018 mm. in diameter, mostly single, occasionally 2- to 4-compound, the grain showing occasionally a central cleft; calcium oxalate crystals numerous, in monoclinic prisms from 0.01 to 0.045 mm. in length; fragments of leptomes or sieve with accompanying yellowish-brown resin cells; tracheæ mostly with reticulate thickenings and simple or bordered pores and associated with short wood-fibers having prominent oblique pores; stone cells of variable shape and varying from 0.04 to 0.11 mm. in length, the walls being from 0.006 to 0.012 mm. in thickness, slightly lignified and traversed with prominent, often branching pores; lignified cork cells relatively few." *U. S. IX.*

The Levant or true scammony root, it is said, averages a little under 9 per cent. of resin, while the Mexican (Ipomœa) root usually yields over 15 per cent. For account of the chemistry and uses of Scammony root, see under *Ipomœa.*

Off. Prep.—Resina Scammoniæ, *Br.;* Tinctura Jalapæ Composita (from Resin), *Br.*

SCILLA. U. S., Br.

SQUILL. Scill.

"Squill is the cut and dried fleshy inner bulb scale of the white variety of *Urginea maritima* (Linné) Baker (Fam. *Liliaceæ*). Squill, in the form of the tincture, properly diluted and injected into the ventral lymph sac of a frog, has a minimum systolic dose (minimum dose producing in one hour a stoppage of the ventricle of the heart in systole) not exceeding 0.006 cc. of tincture, equivalent to 0.000,000,5 Gm. of ouabain, for each Gm. of body weight of frog." *U. S.* "Squill is the bulb of Urginea Scilla, *Steinh.*, divested of its dry membranous outer scales, cut into slices, and dried. When powdered should be kept quite dry over quicklime." *Br.*

Squills; Scille, *Fr.;* Bulbus Scillæ, *P. G.;* Meerzwiebel, *G.;* Scilla, *It.;* Escila (Bulbo de), Cebolla albarrana, *Sp.*

Urginea maritima (*Urginea Scilla* Steinh.) is a perennial herb, with fibrous roots proceeding from the base of a large bulb, which sends forth several long, lanceolate, pointed, somewhat undulated, shining, deep-green leaves. From the midst of the leaves a round, smooth, succulent flower-stem rises, from one to three feet high, terminating in a long, close spike of whitish flowers. The fruit is an oblong, 3-lobed capsule. The squill grows in sandy soil along the sea coast of Spain, France, Italy, Greece, and the other countries bordering on the Mediterranean. The bulbs are collected in August, deprived of their roots and dry membranous outer scales, cut into slices transversely dried in the sun and packed in casks for shipment. The drug is imported from Leghorn, Italy and Amsterdam, Holland.

Properties.—The fresh bulb is pear-shaped, from 15 to 30 cm. in diameter, weighing as much as 5 or 6 pounds, and consists of fleshy scales attenuated at their edges, closely applied over each other, and invested by exterior scales so thin and dry as to appear to constitute a membranous coat. There are two varieties, distinguished as the *red* and the *white squill.* In the former variety which is collected in Algeria and shipped to France, the exterior coating is of a deep reddish-brown color, and the inner scales have a whitish rosy or very light pink epidermis, with a yellowish-white parenchyma; in the latter the whole bulb is white. They do not differ in medicinal virtue. The bulb abounds in a viscid, very acrid juice, which causes it to inflame and even excoriate the skin when much handled. By drying, this acrimony is very much diminished, with little loss of medicinal power. The bulb loses about four-fifths of its weight in the process. The process is somewhat difficult, in consequence of the mucilaginous character of the juice. The bulb is cut into thin transverse slices, and the pieces dried separately by artificial or solar heat. The outer and central scales are rejected, the former being dry and destitute of activity, the latter too fleshy and mucilaginous.

Description and Physical Properties.—"*Unground Squill.*—Irregular, curved or flattened pieces, from 0.5 to 5 cm. in length; yellowish-white, somewhat translucent; brittle when dry, and tough and flexible when damp; odor slight; taste bitter, mucilaginous and acrid.

"*Structure.*—Upper and lower epidermal layers of thin-walled cells with few stomata; mesophyll of slightly elongated thin-walled cells, sometimes containing spheroidal aggregates of a sugar; occasional bundles of spiral and reticulate tracheæ; numerous, elongated mucilage cells containing raphides of calcium oxalate; few spheroidal starch grains in the parenchyma.

"*Powdered Squill.*—Light yellowish-brown; very hygroscopic, caking in moist atmosphere; raphides of calcium oxalate numerous, up to 1 mm. in length, isolated and in bundles imbedded in mucilage; fragments of thin-walled parenchyma with occasionally spiral and reticulate tracheæ; very few starch grains. Preserve in tightly closed containers in a cool place.

"**Assay.**—Prepare a tincture according to the official process and proceed as directed under *Tinctura Digitalis.*" *U. S.*

"In curved, yellowish-white, somewhat translucent strips, from about two and a half to five centimetres long, frequently tapering towards both ends; tough and slightly flexible while moist, but brittle and easily pulverisable when dry. Almost inodorous; taste disagreeably bitter. Ash not more than 5 per cent." *Br.*

Examined by the microscope, each bulb scale, representing a modified leaf, is seen to be pervaded by innumerable minute acicular crystals of calcium oxalate. Some of these attain a length of a millimeter. According to Hartwich, the mucilage occurs either in the form of large drops, filling the parenchymatous cells, or as masses enclosing the raphides. For an elaborate microscopic study, with plates, see *A. Pharm.*, July, 1889. When kept in a dry place, squill retains its virtues for a long time; but if exposed to moisture it soon becomes mouldy.

The virtues of squill are extracted by alcohol, but apparently only in part by water.

Constituents.—The chemistry of squill has been studied by Jarmersted (*A. E. P. P.*, 1879, xi, 22), Merck (*Ph. Ztg.*, 1879), Wanizewski (*A. J. P.*, 1893, 498), Buschmann (*A. Pharm.*, 1920) and Ewins (*J. P. Ex. T.*, 1911, iii, 155), but none of these investigators have isolated any active principles in a pure form. The substances described as *scillitoxin, scillipicrine,* and *scillin,* while more or less active, are apparently none of them even approximately pure. *Scillain* is apparently identical with scillitoxin. Although Wanizewski claimed to have separated three crystallizable substances—*scillinine, scillipicrine* and *scillimarine*—there is no sufficient experimental proof to substantiate this claim.

Ewins separated from the squill two active principles, although neither of them in crystallizable form. The first is water soluble glucoside, which is fatal to the frog in doses of 0.03 Gm. for a 25 gramme frog. The second is a resinous body, very slightly soluble in water, but readily so in alcohol. Fatal dose for a frog is 0.06. Besides these they found a trace of caffeine.

Schmiedeberg found a peculiar mucilage, analogous to dextrin, which he calls *sinistrin,* $(C_6H_{10}O_5)_n$. It is white, easily soluble in water, insoluble in alcohol, lævo-rotatory; on boiling with dilute sulphuric acid it yields levulose and an inactive sugar of reducing properties. The mucilage is not affected by saliva or diastase. This last statement, however, was contradicted by F. Kurtz (*A. J. P.*, 1894, 246), who says that diastase acts upon it, producing a reducing sugar. Kurtz also obtained a reducing sugar (probably dextrose) along with the gum direct by extracting the bulb with hot alcohol.

Uses.—Squill belongs to that series of drugs, commonly known as the digitalis group, which have for their characteristic properties the power of slowing and strengthening the pulse, of contracting the blood vessels, and in toxic doses causing systolic spasm of the frog's heart. (See *Digitalis.*) While it in many regards closely resembles digitalis in its physiological action, it is notable for the strong degree of vasomotor action and for its local irritant effect.

The medical reputation of squill was originally as a diuretic. The older authorities attributed its diuretic action to a direct stimulant effect upon the kidney, but White and Balboni (*J. A. M. A.*, 1920, lxxv, p. 971) who made careful studies on cardiac cases, were unable to perceive any diuretic action which could not be explained through the effects upon the circulation.

While squill is capable of exercising the characteristic effects of the digitalis group on the heart, and might therefore be useful in chronic *heart disease,* it is certainly a much less reliable drug for this purpose than digitalis. Physicians of the past generation, believing it had a direct diuretic action, favored it especially in cases which were associated with *dropsy.* When given in large dose, partly because of the central emetic effect which is characteristic of the digitalis group, but largely because of its local irritant influence upon the stomach, it produces severe nausea and even vomiting. In overdoses it has been known to cause hypercatharsis, strangury, bloody urine, and fatal inflammation of the stomach and bowels.

Like other emetic drugs, if given in sufficient doses to nauseate it tends to increase the bronchial secretions and is occasionally used as an expectorant in *bronchitis* and *spasmodic croup.* Because of its potent action upon the circulation its use for this purpose, however, is not to be encouraged.

Neither water nor dilute acetic acid entirely extract the activity of squill. The only liquid preparations, therefore, which thoroughly represent the drug are those made with alcohol, of which the tincture is probably the better.

When given in substance it is most conveniently administered in the form of pill.

Dose, of squill, from one to two grains (0.065–0.13 Gm.).

SCOPARII. N. F., Br.

SCOPARIUS Scopar. [Broom Tops]

"Scoparius consists of the dried tops of *Cytisus scoparius* (Linné) Link (Fam. *Leguminosæ*). Scoparius contains not more than 5 per cent. of stems over 3 mm. in diameter and not more than 2 per cent. of other foreign organic matter." *N. F.*

"Broom Tops are the fresh and the dried tops of Cytisus scoparius, *Link.*" *Br.*

Scoparius Cacumina, *Br.;* Herba Scoparii; Spartium; Irish or Scotch Broom; Besom; Genêt à balais, *Fr.;* Gemeine Besenginster, Besenginster, Besenkraut, Pfriemenkraut, *G.*

Cytisus scoparius is a common European shrub, cultivated as a sand-binder and locally naturalized on the Atlantic Coast at Nova Scotia and from northern Massachusetts to Virginia. It is a low, densely branched, glabrous shrub, from three to eight feet high, with numerous straight, pentangular, bright green, very flexible branches, and small, oblong leaves, usually trifoliate, but on the upper part of the plant sometimes simple. The flowers are numerous, papilionaceous, large, showy, of a golden-yellow color, and solitary or in pairs upon short axillary peduncles. The seeds are contained in a compressed legume, which is hairy at the sutures. It is essential that true broom be carefully distinguished from *Spanish broom* (*Spartium Junceum*), since a number of cases of poisoning have occurred from the substitution of the dried flowers of Spartium for those of broom. (See Part II.)

The whole plant has a bitter, nauseous taste, and, when bruised, a strong, peculiar odor. The tops of the branches are used in medicine.

Description and Physical Properties.—"*Unground Scoparius.*—Stems thin, flexible, with branched twigs, from 1 to 3 mm. in thickness, more or less angled and winged; externally dark green, nearly glabrous, with numerous reddish brown cork patches; internally yellowish, fracture short-fibrous, that of thicker pieces tough and splintery; leaves present in small amount or absent, upper leaves sessile, with often only one obovate leaflet. Odor slight, on bruising more distinct and peculiar; taste disagreeable, bitter.

"*Powdered Scoparius.*—Dark green; non-glandular, non-lignified hairs, unicellular, pointed, very long and more or less curved with thick walls over which are numerous small projections; fragments of leaf and stem tissue composed of chlorenchyma or epidermis, broadly elliptical stomata from 0.022 to 0.035 mm. in length; fibers with thin walls and simple pores, the fibers from 0.006 to 0.025 mm. in diameter and associated with pith and wood parenchyma and tracheæ with spiral thickenings; starch grains occasional, from 0.007 to 0.020 mm. in diameter; pollen grains few." *N. F.*

"Stem dark green, with long, straight, slender, alternate branches; the latter, like the upper part of the stem, winged, tough, flexible and glabrous. Leaves, when present, small, sessile, and simple above, stalked and trifoliate below. Odor of the fresh tops, especially when bruised, characteristic; the dry tops almost inodorous." *Br.*

The seeds are reported to be used sometimes, and to be as active as the tops. Farwell (*A. J. P.,* 1922, xciv, 429) says that the *Osyrius alba* is common in the market as a substitute for, or an adulterant of, Scoparius. There is considerable resemblance between the two but in the crude drug they can be distinguished by the fact that in the osyrius the stems are many striated, instead of five-angled as in the scoparius, and that the leaf buds are at the apex of the angles, instead of in the channels between them, and that the wood of the osyrius is white instead of yellowish. The powder of the osyrius is of much lighter color than that of the scoparius.

Constituents.—According to Cadet de Gassicourt, the flowers contain volatile oil, fatty matter, wax, chlorophyll, yellow coloring matter, tannin, a sweet substance, mucilage, albumen, and lignin. Stenhouse has separated from them two principles, *scoparin* and an alkaloid *sparteine.* Scoparin is a neutral substance. Stenhouse gives its composition as $C_{21}H_{22}O_{10}$, but Goldschmidt and Himmelmayer (*Ap. Ztg.,* 1893, 566) give the following formula: $C_{10}H_{16}O_8(OH)(OCH_3)$. It is in stellate crystals, only slightly soluble in cold water, more readily in hot water with greenish light yellow color, easily soluble in alkaline solutions or in alcohol. It is decomposed by heat. When fused with potassium hydroxide it yields, according to Hlasiwetz, phloroglucin and protocatechuic acid. *Sparteine,* $C_{15}H_{26}N_2$, was first obtained by distillation from the mother waters of the scoparin. Broom tops yield from 0.23 to 0.68 per cent. of sparteine, according to the time of collection, being richest in spring and poorest in summer at the flowering time of the plant. It is a colorless liquid having a peculiar bitter taste, and all the properties of a volatile alkaloid. Its sulphate occurs in colorless crystals, and is freely soluble in water. (See *Sparteine Sulphate,* Part II). For the commercial extraction of sparteine the ground drug is macerated for several days in a weak solution of sulphuric acid. This infusion is neutralized and evaporated to a syrupy consistency. It is then made alkaline and subjected to steam distillation. The volatilized sparteine is converted into the sulphate and purified by crystallization from water and finally from alcohol.

By the action of potassium dichromate and sulphuric acid, *oxysparteine,* $C_{15}H_{24}N_2O$, is formed, which has been used in medicine (see Part II). For further chemistry of sparteine and its derivatives see Schmidt, *Pharmaceutische Chemie,* 3te Auf., Bd. ii, 1276 and Henry, *Plant Alkaloids,* 2nd ed., 1924, p. 120. Yaleur (*C. R. A. S.,* 1918, clxvii, p. 163) has reported two other alkaloids, one volatile and one non-volatile; the former he calls *Genisteine* and gives it the formula $C_{16}H_{28}N_2$; the second he names *Sarothamnine,* $C_{15}H_{24}N_2$.

Uses.—Scoparius is diuretic and cathartic, and in large doses emetic, and has been employed with advantage in *dropsy.* Cullen prescribed it in the form of decoction, made by boiling half an ounce of the fresh tops in a pint of water down to half a pint, of which he gave a fluidounce (30 cc.) every hour until it operated by stool or urine. The seeds may be given in powder, in the dose of from ten to fifteen grains (0.65–1.0 Gm.).

Scoparin probably represents the diuretic and purgative influences of scoparius, although its physiological and therapeutic properties have not as yet been sufficiently investigated. For description of the effects of sparteine, see *Sparteine Sulphate.*

Dose, of scoparius, ten to fifteen grains (0.65–1.0 Gm.).

Off. Prep.—Fluidextractum Scoparii, *N. F.;* Infusum Scoparii, *Br.;* Succus Scoparii, *Br.*

SCOPOLAMINÆ HYDROBROMIDUM.
U. S. (Br.)

SCOPOLAMINE HYDROBROMIDE Scopolamin. Hydrobrom. [Hyoscine Hydrobromide]

"The hydrobromide [$C_{17}H_{21}O_4NHBr.3H_2O$] of lævorotatory scopolamine obtained from plants of the *Solanaceæ.*" *U. S.* "Hyoscine Hydrobromide, $C_{17}H_{21}NO_4$, HBr,$3H_2O$, is the hydrobromide of an alkaloid, hyoscine or scopolamine, obtained from various plants of the natural order Solanaceæ." *Br.*

Hyoscinæ Hydrobromidum, *Br., U. S. VIII;* Hyoscine Hydrobromide; Bromhydrate d'Hyoscine, *Fr.;* Scopolaminum Hydrobromicum, *P. G.;* Skopolaminhydrobromid, *G.;* Hyoscinum Hydrobromicum; Hydrobromate of Hyoscine.

Scopolamine, $C_{17}H_{21}O_4N$, is found in the leaves and seeds of *Hyoscyamus niger, Duboisia myoporoides, Scopola japonica, Atropa Belladonna* and other solanaceous plants. The term hyoscine, although originally applied to the substance now known as tropine, was used by Ladenburg for an alkaloid that he obtained from hyoscyamine which he believed to be isomeric with atropine. It is now generally held that he was mistaken in his statement concerning the composition of this alkaloid and that the substance with which he was dealing was in reality the alkaloid scopolamine, which however was not discovered until some years later by Schmidt (*A. Pharm.,* 1890, ccviii, 139, and 1892, ccxxx, 207). At present the terms hyoscine and scopolamine are used interchangeably, the Br. Pharmacopœia giving the preference to hyoscine by virtue of its priority, while the American and most of the European Pharmacopœias give a preference to scopolamine because of a greater accuracy. There is, however, in some parts a tendency to apply the word scopolamine to the optically inert alkaloid (analogous to atropine) which Hesse has called *atroscine,* and to save the word hyoscine to indicate lævo-scopolamine. When pure, it forms a syrupy liquid. The best salt for practical use is the hydrobromide.

Description and Physical Properties.—"Colorless, transparent, rhombic crystals, sometimes of large size. It is odorless, and slightly efflorescent. *Caution—Scopolamine Hydrobromide is extremely poisonous.* One Gm. of Scopolamine Hydrobromide is soluble in 1.5 cc. of water and in 20 cc. of alcohol, at 25° C. It is slightly soluble in chloroform, but insoluble in ether.

"When anhydrous, Scopolamine Hydrobromide melts between 190° and 192° C. The specific rotation $[\alpha]_D$ of the salt, determined at 25° C., in an aqueous solution containing the equivalent of 5 Gm. of anhydrous Scopolamine Hydrobromide in 100 cc. of solution, and using a 100 mm. tube, is not less than −22° and not more than −25.75°. Add 5 drops of nitric acid to about 0.01 Gm. of the salt, and evaporate the solution to dryness in a porcelain dish on a water bath: the residue yields a violet color upon the addition of alcoholic potassium hydroxide T.S. Add a few drops of chlorine T.S. to 1 cc. of an aqueous solution of the salt (1 in 20), and shake the mixture with 1 cc. of chloroform: the latter assumes a brownish color. Silver nitrate produces in an aqueous solution of the salt (1 in 20) a yellowish-white precipitate insoluble in nitric acid but soluble in ammonia T.S.

"Its aqueous solution (1 in 20) is neutral, or at most only slightly acid to litmus paper." *U. S.*

"Small, colorless, transparent, non-deliquescent rhombic crystals. Soluble in 4 parts of *water.* Loses about 12 per cent. of its weight when dried at 100° C. Yields the *reactions* characteristic of bromides. An aqueous solution (5 in 100) yields with *solution of sodium hydroxide* a white precipitate soluble in excess of the reagent, but no precipitate with *solution of ammonia.* The alkaloid removed from the ammoniacal solution by shaking with *chloroform,* separating and evaporating the chloroformic solution, when dissolved in *diluted hydrochloric acid,* yields with *solution of auric chloride* a yellow precipitate, which, recrystallised from *water* acidified with *hydrochloric acid* and dried, melts at 198° to 200° C. Treated with *nitric acid* as described under 'Atropina' a violet color is developed. No appreciable ash." *Br.*

Scopolamine when boiled in dilute alkali solution is hydrolyzed into tropic acid (see under *Atropina*) and a new base called *oscine* or *scopoline* $C_8H_{13}O_2N$. According to Cushny (*J. P. Ex. T.,* 1921, xvii, 41), both tropic acid and oscine contain asymmetric carbon atoms and are therefore optically active. It is, therefore, theoretically possible to have four combinations of these optical isomers, but only two have actually been prepared, namely—the l- and d-tropyl esters of dl-oscine; these are the products commonly referred to as lævo- and dextro-scopolamine.

Although the alkaloid scopolamine occurs like hyoscyamine in an optically inert and in a lævo-rotatory form, there is no such common distinction made in its nomenclature as is made in the case of hyoscyamine. While the Br. makes no distinction, except by melting point, the U. S. specifies an optical rotation of not less than 22.

Schmidt (*A. Pharm.*, 1915, pp. 497, 604) has stated that scopolamine is an alcohol $C_8H_{12}(NO)(OH)$ and that upon heating with hydrobromic acid it yields hydroscopolamine bromide $C_{18}H_{12}BrN(OH)_2$ and this upon reduction with zinc and sulphuric acid yields hydroscopolamine $C_{18}H_{13}N(OH)_2$. *Hydroscopolamine* when oxidized is converted into methyl-piperidine-dicarbonic acid. This is a derivative of *pimelenic* acid. For further information on the chemistry of solanaceous alkaloids, see *Belladonnæ Radix.*

Straub has stated that stable solutions of scopolamine may be made by using a 10 per cent. solution of mannitol and then sterilizing. (*Bull. Chim. Farm.* through *Chem. Abst.*, 1918, xii, 1103.)

Uses.—The older investigations into the effects of scopolamine upon the bodily functions are in many regards confusingly contradictory because of the failure to realize the difference in the physiological effects of *racemic* and *lævo-scopolamine.* While these two varieties of the alkaloid possess qualitatively the same physiological properties their actions are quantitatively so different that it is not to be wondered that different pharmacologists obtain such varying results. Lævo-scopolamine (the variety recognized by the U. S. P.) is paralyzant to the peripheral ends of the so-called autonomic, or parasympathetic, nerves acting in this regard precisely like atropine, although less powerful. By virtue of this action it dilates the pupil, causes dryness of the throat and of the skin, accelerates the heart's action, etc. It differs strikingly from atropine, however, in that it is not stimulant to the medullary centers and therefore does not increase the respiration nor elevate the blood pressure; and also in that it appears to act frequently as a cerebral depressant and tends to promote sleep. In some persons the sleep which it produces is interrupted by, or attended with, a kind of low muttering delirium, recalling the mental confusion of atropine poisoning. A striking feature of the effects of large doses of scopolamine is the loss of memory for events which happened while under its influence. It has slight analgesic properties, but according to the researches of Hauchold (*Z. E. P. T.*, 1910, vii, p. 743) greatly enhances the effect of other narcotics such as morphine or urethane. In large dose it is depressant to the respiratory center and apparently also in some degree to the motor ganglia of the spinal cord. The *racemic scopolamine*—sometimes known as atroscine—according to the studies of Cushny (*A. E. P. P.*, 1912, lxx, p. 433), differs from the optically active alkaloid only in being much less powerful in its effects upon the autonomic nerves. When locally applied it will cause dilatation of the pupil, but except in very large doses, it has no effect upon the pulse rate and scarcely any upon the secretions. Its action upon the central nervous system is about equal to that of the lævo-scopolamine.

The most important use of scopolamine is as a cerebral sedative. In ordinary *insomnias* it is usually much less efficient than the narcotics of the aliphatic group but is often useful as an adjuvant in the severer types of sleeplessness, such as seen in *delirium tremens.* In the *manias* it often acts most happily and in some cases even seems to exercise some curative influence. For the relief of *pain* it is rarely useful by itself, but may be advantageously combined with morphine. It is often of value as a symptomatic remedy in various forms of nervous excitement, such as is seen in *hysteria* or *neurasthenia.* It is probably its action upon the intellectual centers which make it so useful a drug in the treatment of *alcoholic* and other *drug habits.*

In a variety of other conditions of nervous excitement scopolamine has been found clinically useful, although its mode of action is not always clear; thus in *epilepsy,* while by itself of little avail, it greatly increases the effects of bromides; in *paralysis agitans* it is one of the most valuable drugs we possess; it is also useful to allay *sexual excitement* as *nymphomania* and *spermatorrhea,* and Hotz (*D. M. W.*, 1908) reports good results even in *tetanus.* As a mydriatic it is much quicker and less permanent in its effects than atropine and is therefore often used to paralyze accommodation in correcting errors of refraction.

In 1900 Schneiderlin, under the misapprehension that scopolamine was stimulating to the respiratory center and would therefore antagonize depressant effects of morphine, introduced the use of a combination of these alkaloids as a means of producing surgical anesthesia. Under the catchy name of "*Twilight Sleep*" this method of anesthesia has been used to a large extent not only for surgical operations, but in obstetrics, either by itself or as a preliminary to the use of chloroform or ether. As the sole means of producing unconsciousness for surgical operations the *scopolamine-morphine anesthesia* is certainly not to be recommended as a routine measure. Not only is the anesthesia unsatisfactory in a very large proportion of cases, but the method has given an extraordinarily high mortality. In 1906, H. C. Wood, Jr. (*Amer. Med.*, xii, p. 544), collected statistics of two thousand cases showing a mortality of 1 in 221 anesthesias, and Avarffi subsequently (*J. A. M. A.*, 1910, liv) in six thousand anesthesias found a mortality of 1 in 150. In obstetrical practice, however, it has been widely applauded and is apparently much less dangerous, at least to the mother, than in general surgery. Schwarz and Krebs (*J. A. M. A.*, 1923, lxxxi, 1083) report on 3000 cases of labor in which scopolamine-morphine anesthesia was successfully used, but conclude that the method to be safe for both child and mother requires such constant observation of the patient as is only possible in hospitals, and the treatment should therefore not be recommended for private practice. The question, however, of whether the use of scopolamine as a preliminary to ether anesthesia is advantageous or not is, as yet, a matter of great difference of opinion. While it is undoubted that the quantity of ether under such circumstances is less than that ordinarily required, it is not certain whether the danger is consequently diminished or not.

The ordinary dose of scopolamine ranges from 1/200 to 1/100 of a grain and occasionally even somewhat more. Many persons, however, are excessively susceptible to its influence and even these quantities may cause toxic symptoms. While scopolamine poisoning very rarely ends fatally the symptoms are often extremely alarming. There are marked disturbances of intellection, sometimes an active delirium resembling that of atropine poisoning and at others simply complete disorientation. Many cases present marked somnolence, but in others this may be lacking. At times the pupils are dilated, the pulse rate accelerated and there is dryness of the mouth with a peculiar husky character to the voice apparently due to laryngeal paralysis, but these symptoms are often absent or very mild, presumably dependent upon the variety of the alkaloid. The condition rarely requires active treatment but if there is serious embarrassment of the respiration strychnine may be used; it is usually better not to employ any drugs for the relief of the delirium, although if very active small doses of paraldehyde and bromides may be employed.

Dose, one two-hundredth to one-eightieth of a grain (0.0003–0.0008 Gm.).

SCUTELLARIA. N. F.

SCUTELLARIA Scutellar. [Skullcap]

"Scutellaria is the dried overground portion of *Scutellaria lateriflora* Linné (Fam. *Labiatæ*). Scutellaria contains not more than 3 per cent. of foreign organic matter." *N. F.*

Skullcap; Scullcap; Quaker Bonnet; Hoodwort; Madweed; Mad-dog or Sideflowering Scullcap; Blue Pimpernel; Hooded Willow-herb; Helmet Flower; Scutellaire, *Fr.;* Helmkraut, Schildkraut, *G.*

Several species of *Scutellaria* have attracted attention. *Scutellaria galericulata* L., which grows in wet places from Newfoundland to North Carolina and west to Nebraska, has a feeble, somewhat alliaceous odor, and a bitterish taste. It has been employed in intermittents, and externally in old *ulcers. S. integrifolia* L. is intensely bitter, and might probably be found useful as a tonic.

Scutellaria lateriflora is an indigenous, perennial herb, with a stem erect, much branched, quadrangular, smooth, and one or two feet high. The leaves are ovate, acute, dentate, subcordate upon the stem, opposite, and supported upon long petioles. The flowers are small, of a pale blue color, and disposed in long, lateral, 1-sided, leafy racemes. The fruit consists of four brown nutlets, enclosed by a persistent calyx having a shape quite similar to the head covering formerly worn by the women of the Quaker sect. The plant grows in wet shaded places in the United States and Canada. It is collected in summer when in flower and dried. The commercial supplies are largely obtained from the Southern and Western States.

Scutellaria has been one of the most substituted and adulterated drugs in the Materia Medica. While the *S. lateriflora* Linné is alone officially recognized as the source of the drug, various other native species of *Scutellaria* have more frequently represented the article of commerce than the officially specified herb. Chief among these have been *S. canescens* Nutt. or *Western Scullcap, S. cordifolia* Muehl. or *Southern Scullcap* and *S. galericulata* L.

Description and Physical Properties.—"*Unground Scutellaria.*—About 50 cm. in length or in shorter broken pieces, smooth; stem quadrangular, branched; leaves opposite, smooth, petiolate, about 5 cm. in length, ovate-lanceolate or ovate-oblong, serrate; flowers about 6 mm. in length, in axillary one sided racemes, with a pale blue corolla and bilabiate calyx, closed in fruit, the upper lip helmet-shaped. Odor slight; taste slightly bitter.

"*Powdered Scutellaria.*—Dark green; non-glandular hairs numerous, long, 1- to 3-celled with walls having numerous small centrifugal projections, the basal cell large, broadly cylindrical, the apical cell narrowly tapering, often recurved; glandular hairs with 1- to 2-celled stalks and 4-celled heads, the latter from 0.015 to 0.045 mm. in diameter; pollen grains smooth, nearly spheroidal from 0.015 to 0.025 mm. in diameter; fragments composed of chlorenchyma, epidermal cells and stomata, the latter broadly elliptical, about 0.020 mm. in length; long lignified fibers with simple pores and walls about 0.005 mm. in thickness; tracheæ narrow, mostly with scalariform or reticulate thickenings; occasional fragments composed of distinctly striated epidermal cells of corolla, the fragments often colored pink in chloral hydrate T.S." *N. F.*

H. Molisch and G. Goldschmidt (*Ph. Ztg.,* Dec. 4, 1901, 965) obtained from scutellaria and a number of other labiates an identical body, to which they gave the name *scutellarin.* It is present in all of the different scutellarias, being most abundant in the upper epidermis of the leaf, but found also in the roots, stems and flowers of the plant. It was further obtained from the leaves of *Galeopis Tetrahit* L., and of *Teucrium Chamaedrys* L. Scutellarin is obtained by boiling freshly gathered leaves for fifteen minutes in ten times their weight of water, filtering the decoction and adding from 1 to 2 per cent. of hydrochloric acid, which causes an abundant precipitate of scutellarin. If precipitation is effected from the hot solution, the scutellarin separates in the form of light yellow crystals. The formula $C_{10}H_8O_3$ has been assigned to scutellarin. Its alcoholic solution gives a red precipitate with lead acetate and an intense green color with ferric chloride, changing on heating to a red color if the reagent is not present in great excess; alcoholic potassium or sodium hydroxides, as also alkali acetates, produce reddish-yellow precipitates, which change to green on exposure to the air. Solution of barium hydroxide has the same effect. The green color is produced immediately if an oxidizing agent, such as chlorine or bromine water, is added.

Uses.—Scullcap is as destitute of medicinal properties as a plant may well be, not even being aromatic. When taken internally, it produces no very obvious effects, and probably is of no remedial value, although at one time it was esteemed as a remedy in *hydrophobia.* It has also been used in *neuralgia* and *epilepsy, chorea, delirium tremens,* and *nervous exhaustion* from fatigue or over-excitement. (See Bramwell, *B. M. J.*, 1916.) Dr. P. E. Hommell proposes formulas for various pharmaceutical preparations of scutellaria in an article in the *Druggists' Circular,* 1915, 797.

Dose, thirty to ninety grains (2.0–5.8 Gm.).

Off. Prep.—Fluidextractum Scutellariæ, *N. F.;* Tinctura Viburni Opuli Composita, *N. F.*

SENECIO. N. F.

SENECIO [Life Root Plant]

"Senecio is the dried plant of *Senecio aureus* Linné (Fam. *Compositæ*). Senecio contains not more than 10 per cent. of foreign organic matter." *N. F.*

Life-root, Golden Life-root, Ragwort, Golden Ragwort.

Several of the species of *Senecio* have been used in medicine. Among them are *S. vulgaris* L. (*Groundsel, Jacobskraut* G.) and the *S. Jacobœa* L. The official species, *S. aureus,* is a common indigenous perennial herb found in swamps and wet meadows, about 1 or 2 feet in height, bearing several floral heads, both the disk and ray flowers being of a golden yellow color. The commercial supplies of the drug are obtained chiefly from the central states.

Description and Physical Properties.—"*Unground Senecio.*—Stems from 3 to 6 dm. in length, if entire bearing a basal rosette of leaves; sparingly clothed with successively smaller leaves and bearing at the summit several yellow heads in a loose corymb, white floccose when young, but mostly glabrous when expanded, radical leaves on long, slender petioles, mostly of rounded form from 5 to 7 cm. in breadth, the base often cordate, the summit rounded, the margin crenate-dentate; stem-leaves gradually changing from the shape of the radical leaves to lyrately pinnate, then pinnatifid and sessile, and at length clasping, oblong and incised; heads slender peduncled from 12 to 25 mm. in width, the lance-linear involucral scales in about two series, closely appressed, rays about ten, bright-yellow, disk flowers very numerous, small, bearing a glabrous achene and a white pappus. Odor characteristically aromatic; taste bitter, slightly astringent and distinctly acrid and pungent.

"*Powdered Senecio.*—Dark green; numerous very long, much twisted or bent multicellular non-glandular hairs with thin walls and some with an oily content; fragments of leaf tissue composed of chlorenchyma, epidermal cells and elliptical stomata, the latter from 0.020 to 0.035 mm. in length; stem tissue composed of wood parenchyma and long thin-walled lignified fibers and tracheæ, the latter with spiral thickenings or simple pores; pollen grains few, or wanting, from 0.020 to 0.035 mm. in diameter." *N. F.*

Toxic alkaloids have been found in several species of Senecio, thus Watt (*Tr. Chem. Soc.*, 1909, xcv, 466) has found *senecifoline,* $C_{18}H_{27}O_8N$, and *senecifolidine,* $C_{18}H_{25}O_7N$, in the *S. latifolius.* We know of no chemical studies, however, of the official species.

In *S. vulgaris,* Grandval and Lajoux (*C. R. A. S.*, 1895, cxx, 1120) found two alkaloids, *senecionine,* $C_{18}H_{25}O_6N$, which is slightly, and *senecine,* which is readily, soluble in ether. According to Wiet, senecionine is a paralyzant of the peripheral motor and sensory nerves, while Bunch has found that the alcoholic extract of *Senecio Jacobœa* is capable of producing a rise of the arterial pressure due to contraction of the arterioles, followed, if the dose has been large enough, by arterial dilatation with fall of pressure. (*B. M. J.*, 1900, ii, 212.)

The rhizomes of the Mexican species, *Senecio grayanus* Hemsl. and *S. cervariæfolius* Sch., constitute *maturin,* the plants being known as *matarique, maturin,* or *guerena.* They produce rise of temperature, dilatation of the pupil, and violent tetanic spasms. Henckel states that they contain a glucoside resembling digitalin. (*A. J. P.*, Jan., 1891; also *Nouv. Rem.*, 1888, and *P. J.*, March, 1889.)

Uses.—Ragwort was formerly believed to exercise some peculiar influence upon the female generative organs and was used in such opposite conditions as *amenorrhea* and *menorrhagia,* as well as in various other uterine and in urinary diseases. It is, however, scarcely ever prescribed by regular physicians, and there is no reason to suspect it of therapeutic virtues.

The *S. vulgaris* and *S. Jacobœa* are of importance because of their toxic effects and have given rise to a peculiar type of poisoning in cattle and horses in South Africa. Cushny investigated the two alkaloids, *senecifoline* and *senecifolidine,* which are actively poisonous, causing symptoms similar to those which have occurred in animals after eating the compound. The most characteristic pathological lesion was cirrhosis of the liver.

Dose, of the fluidextract, one fluidrachm (4 cc.).

Off. Prep.—Fluidextractum Senecionis, *N. F.*

SENEGA. U. S. (Br.)

SENEGA Seneg. [Senega Snakeroot]

"Senega is the dried root of *Polygala Senega* Linné (Fam. *Polygalaceæ*). Senega contains not more than 5 per cent. of stems and other foreign organic matter." *U. S.* "Senega Root is the dried root of Polygala Senega *Linn.*" *Br.*

Senegæ Radix, *Br.;* Rattlesnake Root, Mountain Flax, Senega or Seneca Root, Radix Polygalæ Virginianæ; Polygala de Virginie, *Fr.;* Radix Senegæ, *P. G.;* Senegawurzel, Klapper-Schlangenwurzel, *G.;* Poligala Virginiana, *It.;* Poligala de virginia (Raiz de), *Sp.*

Polygala Senega is an indigenous herb with a perennial branching root, from which several erect, simple, smooth, round, leafy stems annually rise, from nine inches to a foot in height. The stems are occasionally tinged with red or purple below, but are green near the top. The leaves are alternate or scattered, lanceolate, pointed, smooth, bright green on the upper surface, paler beneath, and sessile or short petiolate. The flowers are small and white, and form a close spike at the summit of the stem. The calyx is their most conspicuous part. It consists of five sepals, two of which are wing-shaped, white, and larger than the others. The corolla is small and closed. The capsules are small, much compressed, obcordate, two-valved and two-locular, with two oblong-ovate, blackish, hairy seeds, slightly longer than the lobes of the caruncle.

This plant is found in woods and rocky soil of southern Canada and the eastern United States, south to Georgia and west to Wisconsin, Minnesota and Missouri. At one time it was largely collected in eastern Canada and the north-eastern Atlantic states; when this supply was exhausted, Kentucky and the States west and southwest of it were invaded; then Wisconsin and the northwestern states, from which with western Canada the commerce at present derives its chief supply. There are two varieties of the plant, the typical *P. Senega,* the form found in the Northern United States, and the variety *latifolia* (T. and G.) which extends from Maryland and Pennsylvania to the Dakotas and Tennessee. This variety is distinguished by its height (from ten to twenty inches) and its very large, ovate or ovate-lanceolate leaves, which taper towards each end and attain a length of four inches. The root of commerce is obtained from both varieties. It is brought into market in bales weighing from fifty to four hundred pounds. See True (*Ph. Era,* 1913, xlvi, p. 68).

Owing to the extensive use of senega considerable interest is manifested in the cultivation of the plant. Hood reports to have demonstrated that it can be successfully cultivated. (*Vermont Sta. Rept.,* 1907, p. 371.) It has also been grown by the Bureau of Plant Industry, U. S. Dept. of Agriculture.

Senega root varies somewhat in appearance according to the locality from which it is derived, and local varieties are recognized in commerce. Two varieties of senega occur in commerce, *viz.,* Northern and Southern Senega.

Northern or *Manitoba Senega* has the larger roots, being up to 15 cm. long and 12 mm. in thickness. Externally, it is dark brown and purplish near the crown. This variety is the more highly esteemed and is largely collected at present in Manitoba, Saskatchewan and Minnesota. *Southern* or *Small Senega* consists of roots up to 8 cm. long and 7 mm. in thickness, with a brownish-yellow color. A large percentage of rootlets are usually found in this variety. Most of it is shipped from South Carolina and Georgia.

Description and Physical Properties.—"*Unground Senega.*—Usually in pieces; when entire, slenderly conical, with an enlarged crown; from 3 to 15 cm. in length and from 2 to 10 mm. in thickness; tortuous, somewhat branched and bearing a few rootlets; crown knotty with numerous buds and short stem-bases; externally brownish-yellow, the crown darker and rose-tinted; longitudinally wrinkled, frequently with a distinct ridge or keel; fracture short, wood pale yellow; odor suggesting methyl salicylate; taste sweetish, afterwards strongly acrid.

"*Structure.*—A corky layer of several rows of tangentially elongated, light yellowish or yellowish-brown cells; outer bark of tangentially elongated parenchyma; inner bark of small groups of sieve tissue associated with parenchyma and alternating with medullary rays 1 to 3 cells wide; cortical cells somewhat collenchymatously thickened and with amorphous contents which form oily drops upon the addition of potassium hydroxide T.S. or of chloral hydrate T.S.; wood usually eccentrically developed, varying in outline, in transverse section, from circular or elliptical to reniform or irregularly fan-shaped or even separated by broad parenchyma rays into two or more masses; the inner bark adjacent to the radially longer wood-wedges thickened proportionally to their increased length and the outer bark opposite the radially shorter or absent wood-wedges also thickened proportionally to their shortness or absence.

"*Powdered Senega.*—Grayish-yellow to light yellowish-brown; somewhat sternutatory; consisting of scattered fragments of cork; fragments of parenchyma and sieve tissue developing oily globules; fragments of tracheæ and short, pointed tracheids with numerous, simple and bordered pores associated with short wood-fibers with oblique slit-like pores and lignified medullary ray cells with large simple pores." *U. S.*

"Greyish or brownish-yellow, slender, usually from five to ten centimetres long, with a knotty crown bearing the bases of numerous, slender, aerial stems; frequently curved or contorted, sparingly branched, keeled, sometimes transversely wrinkled. Fracture short. In transverse section, a horny translucent cortex free from starch grains and a white, often irregularly developed, wood. Characteristic odor; taste at first sweet, afterwards acrid." *Br.*

Holm describes the pharmacognosy of senega root and the morphology of the plant in *M. R.*, 1907, xvi, p. 155. Hartwich has made a very interesting observation in that he has found starch occasionally present in official senega. (*Apoth. Ztg.*, xxvi, p. 84.) Hartwich has also described two false senegas. (*S. W. P.*, xlvi, pp. 537 and 749.) The pharmacognosy of the drug has been well elaborated by Tunmann in *Ph. Zentralh.*, xlix, p. 61. Muller describes and figures senega and a number of the drugs that have been used as adulterants of this drug or as occasional contaminations. (*Pharm. Praxis.*, vii, p. 309.)

The roots of *Panax quinquefolium* L., or ginseng, were at one period frequently mixed with those of senega, but are easily distinguishable by their shape and taste. The roots of *Gillenia trifoliata* (L.) Moench., and *Asclepias Vincetoxicum* L. (*P. J.*, ix, 411), and of *Triosteum perfoliatum* L. (see Part II), have been noted as occurring in commercial senega; they are readily detected by the absence of the keel-like line.

For description of the roots of a number of species of Polygala see *Flora*, Jan., 1886, and *D. C.*, 1901, 26. The properties of senega as well as the medicinal virtues of the root, are extracted by boiling water and by alcohol. Diluted alcohol is an excellent solvent.

Constituents.—Senega owes its activity to two acrid principles called *senegin*, $C_{17}H_{28}O_{10}$, and *polygalic acid*, $C_{19}H_{30}O_{10}$. These substances belong to the group of saponins. *Polygalic acid* is a feebly acidic glucoside which on hydrolysis yields glucose and sapogenin. (For method of its preparation, see *U. S. D.*, 20th ed., p. 989.) It is a white odorless powder, whose taste is at first slight but becomes extremely pungent and acrid. It is soluble in water and in boiling alcohol, which precipitates it on cooling; it is insoluble in ether. It is precipitated from its aqueous solution by both neutral and basic lead acetate. *Senegin*, according to Atlass (*In. Dis.*, 1887), differs from polygalic acid in that it is not acid in reaction and is not precipitated from its aqueous solution by neutral lead acetate although it is by the basic.

Senega also contains, like most of the species of Polygala, small quantities of methyl salicylate which amounts to about 0.25 to 0.30 per cent. (see Reuter, *A. Pharm.*, 1889, 452; and Schroeder, *A. J. P.*, 1896, p. 178).

According to the researches of Trommsdorff and Schneider, saponin is contained solely in the bark, the woody tissues being inert. Kain (*Ph. Ztg.*, 1898, 562) states that he has discovered a lævo-rotatory glucoside distinguished from saponin by its mild taste, solubility in absolute alcohol, and in its not giving a precipitate with barium hydroxide.

Senega yields its virtues to water, cold or hot, but under the influence of heat a portion of the acrid principle unites with the coloring matter and coagulated albumen, and thus becomes insoluble in water. In forming an aqueous extract, the infusion should be prepared by percolation, as it is thus most concentrated, and consequently requires less heat in its evaporation. In preparing the infusion, the temperature of the water should not exceed 40° C. Experience has thoroughly proved the value of the use of an alkali in small proportion in making galenical preparations of senega, it prevents gelatinization and combines with the active principles. (See *Fluidextractum Senegæ.*)

Uses.—Senega owes what therapeutic virtues it possesses to its saponins. (See *Quillaia.*) These by their local irritant action upon the mucous membrane of the stomach tend to cause nausea, thereby increasing the secretions of the sweat glands and especially of the bronchial glands. For this reason the drug has been used as an expectorant in various forms of *bronchitis* and in *asthma.* In overdose it is capable of acting as an irritant poison producing violent vomiting and purging. Polygalic acid may be employed in doses of from one-fourth to one grain (0.016–0.65 Gm.), administered in the form of either pill or capsule.

Dose, of senega, from fifteen to twenty grains (1.0–1.3 Gm.).

SENNA. U. S. (Br.)

SENNA Senn.

"Senna consists of the dried leaflets of *Cassia Senna* Linné, known in commerce as Alexandria Senna, or of *Cassia angustifolia* Vahl, known in commerce as Tinnevelly Senna (Fam. *Leguminosæ*). Senna contains not more than 10 per cent. of its stems, and not more than 2 per cent. of its pods or other foreign organic matter, and yields not more than 3 per cent. of acid-insoluble ash." *U. S.* "Senna Leaves are the dried leaflets of Cassia acutifolia, *Delile*, and of Cassia angustifolia, *Vahl.* Known in commerce as Alexandrian senna, and Tinnevelly senna." *Br.*

Sennæ Folia, *Br.;* Senna Leaves; Séné; Feuilles de Séné, *Fr.;* Folia Sennæ, *P. G.;* Sennesblätter, *G.;* Sena, *It.;* Sen, *Sp.*

The plants which yield *senna* belong to the genus *Cassia*, several species of which have contributed commercial senna of the past. Only two of these, however, are now recognized in the United States and British Pharmacopœias, *viz.*, the *Cassia Senna* L. (*C. acutifolia* Delile) and the *C. angustifolia* Vahl. The leaves of a number of species of Cassia are utilized like senna leaves in the respective countries in which they grow, among which may be mentioned *C. marilandica* L.; *C. cathartica* Mart.; *C. rugosa* Don.; *C. splendida* Vog.; *C. lævigata* Willd.; *C. multijuja* Rich.; *C. Chamæcrista* L.; and *C. montana*

Hayne. Farwell asserts that *Cassia marilandica* and other American species of Cassia have been offered in large lots and sold as senna. (*M. R.*, xvii, p. 35.)

Cassia Senna, which furnishes the Alexandria Senna, is a shrub indigenous to the Anglo-Egyptian Soudan but found growing wild in other parts of Africa and in Hejaz. It has recently been introduced into India where it is now cultivated for the drug. It possesses a straight, branched whitish stem attaining a height of from two to ten feet, depending upon the locality of growth. The leaves are alternate and pinnate, with glandless petioles, and two small narrow pointed stipules at the base. The leaflets, of which from four to six pairs belong to each leaf, are almost sessile, ovate lanceolate, acute, oblique at their base, from half an inch to an inch long, and of a grayish-green color. The flowers are yellow, and in axillary racemes. The fruit is a flat, elliptical, obtuse, membranous, smooth, grayish-brown legume, about an inch long and half an inch broad, and divided into six or seven cells, each containing a hard, heart-shaped, ash-colored seed.

Cassia angustifolia is a low shrub having a habit somewhat similar to *C. Senna.* It is native to Arabia and probably Africa and is found growing in the wild condition in southern Arabia, northern India, Somaliland and the Anglo-Egyptian Soudan. It is cultivated extensively in southern India for medicinal use. It has an erect, smooth stem, and pinnate leaves, with from four to eight pairs of leaflets. These are nearly sessile, lanceolate, obscurely mucronate, oblique at the base, smooth above and somewhat downy beneath, with the veins turned inward so as to form a wavy line immediately within the edge of the leaflet. The most striking character of the leaflet is its length, which varies from 2 to 5 cm. The petioles are without glands; the stipules minute, spreading and semi-hastate. The flowers are bright yellow, and arranged in axillary and terminal racemes rather longer than the leaves. The legume is oblong, membranous, tapering abruptly at the base, rounded at the summit, and 4 to 5 cm. long by about 1.5 cm. broad.

Cassia obovata Colladon, the source of the formerly recognized *Dog Senna* or *Italian Senna*, possesses a rather shorter stem than that of *C. acutifolia*, rising to the height of only a foot and a half. The leaves have from five to seven pairs of leaflets, which are obovate, very obtuse, sometimes mucronate. The flowers are in axillary spikes, of which the peduncles are longer than the leaves of the plant. The legumes are very much compressed, curved almost into the kidney form, of a greenish-brown color, and covered with a very short down, which is perceptible only by the aid of a magnifying glass. They contain from eight to ten seeds. This species grows wild in Syria, the Anglo-Egyptian Soudan and Senegambia. It has been cultivated successfully in Italy, Spain, and the West Indies. It is said to be no longer gathered for senna, although its cut leaflets have been found in cut Alexandria Senna.

Description and Physical Properties.—"*Unground Alexandria Senna.*—Inequilaterally lanceolate or lance-ovate, frequently broken; from 2 to 3.5 cm. in length and from 6 to 10 mm. in width, unequal at the base, with very short, stout petiolules; acutely cuspidate, entire, brittle, subcoriaceous; hairs short and somewhat appressed, few on the upper surface, more numerous on the lower surface, where they occur spreading on the midrib, especially on the lower part; color light grayish-green; odor characteristic; taste mucilaginous, slightly bitter.

"*Unground Tinnevelly Senna.*—Usually unbroken, from 2 to 5 cm. in length, from 6 to 15 mm. in width; broadly acute at the apex, slightly hairy; light yellowish-green and otherwise resembling Alexandria Senna.

"*Structure.*—Epidermal cells polygonal, with straight walls and frequently containing mucilage; stomata numerous, broadly elliptical, mostly from 0.020 to 0.035 mm. in length, usually bordered by 2 neighbor-cells with their long axes parallel with that of the stoma, and rarely, though more frequently in Alexandria Senna, a third epidermal cell at the end of the stoma; hairs non-glandular, 1-celled, conical, often curved, with thick papillose walls, from 0.10 to 0.35 mm. in length; palisade cells in a single layer underlying both surfaces; calcium oxalate in rosettes, in the loose mesophyll parenchyma and in 6- to 8-sided prisms in crystal fibers, surrounding the conducting tissues of the veins.

"*Powdered Senna.*—Light green; displaying fragments of veins bearing lignified tracheæ and crystal fibers, isolated hairs, masses of palisade and mesophyll parenchyma, fragments of epidermis with stomata, free calcium oxalate rosettes and prisms from 0.01 to 0.02 mm. in length. In powdered Alexandria Senna the hairs are more numerous than in powdered Tinnevelly Senna.

"Mix 0.5 Gm. of powdered Senna with 10 cc. of an alcoholic solution of potassium hydroxide (1 in 10), boil the mixture for about two minutes, dilute it with 10 cc. of water, and filter. Acidify the filtrate with hydrochloric acid, shake it with ether, remove the ethereal layer, and shake it with 5 cc. of ammonia T.S.: the latter is colored pinkish-red or bluish-red." *U. S.*

"Pale grayish-green or yellowish-green, thin, brittle; usually from two to four centimetres long, the leaflets of Alexandrian senna being usually smaller than those of Tinnevelly senna; lanceolate, or oval-lanceolate, acute, entire, and unequal at the base. Surface finely pubescent or nearly glabrous; veins on the under surface distinct. Epidermis of both surfaces consisting of polygonal cells and bearing one-celled, thick-walled, warty hairs together with stomata, each stoma being enclosed between two cells with their long axes parallel to the ostiole. The powdered Leaves greenish-yellow, exhibiting, in addition to the characteristic epidermis, stomata, and hairs, elongated palisade cells and grouped sclerenchymatous fibres accompanied by prismatic crystals of calcium oxalate. Ash not more than 12 per cent." *Br.*

1. *Alexandria Senna.*—This variety is the product of *Cassia Senna* Linné. It is gathered from wild plants growing in El Hejaz, from wild and cultivated plants growing in the Soudan below Egypt and to a small extent from plants which have recently been cultivated in India. The Soudan Senna is claimed by Amin to be worthless, although used to adulterate the valuable supplies coming from the Hejaz. The leaflets are usually gathered during the winter months by the natives, dried in the sun and packed in hampers weighing about 225 pounds. Three of these are placed on the back of each camel and carried to Port Soudan and other convenient shipping points, whence the drug is shipped to Alexandria, Port Said or Cairo. Here it is claimed the worthless Soudan Senna has frequently been admixed with senna from Hejaz. About 75 per cent. of the Alexandria Senna imported into the United States comes from Cairo, Alexandria and Port Said, the remaining 25 per cent. comes indirectly through London. C. J. Zufall (*J. A. Ph. A.*, 1921, x, 185) reports that samples of a superior quality of Alexandria Senna which were imported by way of London were found to have been grown by a New York drug importer on his plantation in India. The leaves were hand picked, unbroken and free from stems and dirt, something not true of the senna coming from Soudan.

The chief adulterants of Alexandria Senna have been stems, midribs, dirt, the leaflets and fruits of *Tephrosia apollinea* DC., *Cassia obovata, C. angustifolia, C. auriculata,* worthless Soudan Senna and *Tephrosia apollinea.* The latter is a leguminous plant native to Egypt and Nubia. Its leaflets are averagely smaller than senna, of an obovate-oblong or obcordate outline, with an emarginate apex, downy lower surface and parallel, unbranched, lateral nerves. They are frequently folded longitudinally, which fact often aids their detection. The legumes of this species are 1 to 1½ inches long and up to ⅙ of an inch broad. Examination of recent senna importations at New York revealed considerable adulteration with *Tephrosia apollinea* (*C. D.*, 1917, lxxxix, 385). The leaflets of *C. obovata* are obovate, with obtuse to mucronate apex, 12 to 22 mm. long and about half as wide. The legumes are somewhat reniform, downy and contain 8 to 10 seeds.

A. Joenssen (*C. D.*, 1917, lxxxix, 47) finds that the broken leaflets of *"Arabian" Senna* (*Cassia angustifolia*) and *"dog" Senna* (*C. obovata*) have recently been used to adulterate commercial *"Alexandrian" Senna.* Casparis reports that *"Folia sennæ Palthe,"* a substitute appearing in Austria, is derived from *Cassia auriculata.* A similar substitute appearing in Switzerland and devoid of activity, is probably identical with it. (*Schweiz. Apoth. Ztg.* through *Chem. Abst.*, 1917, xi, 2020.) The leaflets of *Coriaria myrtifolia* L. (see Part II) have been detected occasionally as an admixture in commercial senna, especially the cut Alexandria variety. They are usually cut in several pieces for this purpose. In the entire condition they are ovate-lanceolate, grayish-green with a bluish tint, and are readily known, when not too much broken up, by their strongly-marked midrib and two lateral nerves running from the base nearly to the summit. They are free from hairs and do not contain crystals of calcium oxalate. Surface sections of their lower epidermis, when examined microscopically, show cells with rectilinear vertical walls, scattered among which are stomata, each with two parallel neighboring cells which are strikingly wrinkled.

Formerly *Argel leaves,* the leaves of *Solenostemma Argel* Hayne (Fam. *Asclepiadaceæ*), a native of Africa, were regularly mixed with Alexandria Senna but are now rarely seen in this variety. They somewhat resemble this senna but can readily be distinguished by their thicker texture, curved or curled margins, absence of conspicuous veins, outside of the midrib, and by their 3- to 4-celled, non-glandular hairs.

2. *Indian Senna.*—This variety is the product of *Cassia angustifolia* Vahl. which, while native to southern Arabia, is cultivated in the Anglo-Egyptian Soudan and to a larger extent in southern India, where, especially in the southeastern district of Tinnevelly, the plant produces larger leaves and leaflets than in its native home. The leaflets differ from those of the Alexandria Senna in being yellowish-green, in attaining a larger size, frequently up to 5 and occasionally 5.5 cm. in length, in having a less noticeable asymetrical outline, and in showing fewer hairs. They are collected for the market chiefly in southern India, dried in the sun and packed in bags or pressed into bales for shipment.

The finest grade of Indian Senna is that grown in the district of Tinnevelly and commercially known as *Tinnevelly Senna.* It is gathered from cultivated plants and usually represents leaflets of excellent appearance and free from pods, stems or other foreign matters. Before the World War the purity, high quality and low price of the Tinnevelly Senna placed it in the front rank on the purchasing markets. In 1914, however, its cultivation in Tinnevelly had been almost entirely discontinued due to the low price offered on the European market because of its indiscriminate adulteration. Since the war, it has been less manipulated and is now steadily regaining its lost repute. Tinnevelly Senna is shipped to the United States and Europe from Tuticorin, India, or indirectly to this country through London. Inferior grades of senna, containing discolored leaflets, stems, fruit, etc., have been sent from Aden, Mocha and other Red Sea ports to Bombay. Some of these have been exported from India as "Indian Senna." About 75 per cent. of Indian Senna used in the United States comes from India, the remaining 25 per cent. being imported from London.

Much study has been given to the question of distinguishing the powder of Alexandria and India Senna by means of the microscope. (See papers by Sayre, *A. J. P.,* 1896, 1897; Schneider, *Am. Drug.,* 1897; Denniston, *Ph. Rev.,* vol. xvi.) As a result of these studies it is asserted that it is possible to take advantage of the greater hairiness of the Alexandria Senna as a practical distinction, it being alleged that a fragment of the epidemis of Alexandria leaf contains twice as many hairs as does a similar sized shred of epidermis from the India Senna. It is especially proposed to count the number of epidermal cells between two hairs or their scars, the average distance of the hairs from one another being in the Alexandria Senna three epidermal cells, and in the India six cells. Advantage may also be taken of the difference in the neighboring cells of the stomata; in the majority of stomata, in each case, there are two of the neighbor-cells, but in India Senna the proportion is one having three neighbor-cells to seven having two, and in the Alexandria the proportion is one having three to two having two.

The so-called *Aden Senna,* which Holmes states to be active, is composed of small, broad, not very acute, hairy leaves, and is believed to be obtained from *C. holosericea* Fres. A false senna from Madras has been identified by E. M. Holmes as the product of *Cassia montana* Hayne. The leaflets are about the size of the Tinnevelly Senna, but are distinguishable by obtuse or rounded ends which are with distinctly mucronate (the tip is, however, often broken off and absent from individual leaves), by the obtuse angles of the lateral veins and by the presence of a well marked network of veins of the under surface. Further, the color of the upper surface is distinctly browner than of the Tinnevelly leaflet. The whole leaves of *Cassia montana* have from 10 to 15 pairs of leaflets, while the Tinnevelly Senna has only from 6 to 8 pairs. In the drug this character can usually be made out by noticing the number of scars on the rachis. For a microscopic description of powder, see H. G. Greenish, *P. J.,* lvi, 694. In detecting the adulteration of senna, the apothecary may avail himself not only of the general physical characteristics of the leaves, but also of the fact that while the senna leaf, containing no tannic acid, does not precipitate ferric chloride, most leaves used in adulteration do alter the ferric solution. The microscopic characteristics of the false leaves, though varying greatly, are almost always very different from those of senna. In the senna leaflets the epidermis from the upper and under surface is very similar. The stomata are numerous; the epidermal hairs are unicellular and deciduous, leaving, when detached, a base which has the appearance of an annular pad, around which the neighboring cells seem to radiate. The parenchyma of the cell has a thick epidermis, and is divided into three layers, the uppermost and lowest of which consist of palisade tissue, and are separated by a zone of very small, rounded, parenchymatous cells. Rosette aggregate crystals of calcium oxalate are scattered throughout the parenchyma, and prismatic crystals, one in each cell, occur clustered around the bast tissue of the principal veins.

3. *Arabian Senna.*—This commercial variety consists of the elongated lanceolate leaflets of wild plants of *C. angustifolia,* gathered in southern Arabia and exported from Hodeida to Port Soudan. Thence it is conveyed to Cairo where it is sometimes mixed with Alexandria Senna before packed for export.

4. *Mecca Senna.*—This article is also known commercially as *Bombay Senna* since it is largely shipped from Arabia to that seaport. It is collected both from wild and cultivated plants of *C. angustifolia.* The leaflets are oblong-lanceolate, on the average longer and narrower than those of *C. acutifolia,* and shorter than those of *C. elongata.* The variety in mass appears brownish-green but sometimes has a yellowish or tawny hue, more like that of India than like that of Alexandria Senna.

Constituents.—The cathartic principles of senna are insoluble in strong alcohol but may be extracted by either water or diluted alcohol. The odorous and coloring principles are soluble in either water or alcohol. It is stated that the activity of senna is destroyed by boiling, although there is some difference of opinion on the subject.

Dragendorff and Kubly in 1866 attributed the productive powers of senna to a substance which they called *cathartic acid* (*cathartin* seems to be a mixture containing this substance). Stockman (*P. J.,* 1885, p. 740) found cathartic acid to be glucosidal. It was further investigated by Gensz (*A. J. P.,* 1893, 334) who assigned it the formula of $C_{30}H_{36}NO_{15}$.

According to Groves (*P. J.,* Oct., 1868), both the ammonium and magnesium salts of cathartic acid are active. Tschirch and Hiepe (*A. Pharm.,* 1900, p. 448) besides cathartic acid obtained a mixture of glucosides, which they called *anthraglucosennin,* also *sennanigrin* from which they obtained emodin and chrysophanic acid. Tutin (*Tr. Chem. Soc.,* 1913, ciii, p. 2006) inclines to the opinion that cathartic acid is not a chemical individual. He finds that the only anthraquinone derivatives present are rhein and aloe-emodin with glucosides of the same. (For further account of these principles see under *Rheum.*)

Other peculiar substances which have been found in senna, but probably are not connected with its purgative property, are *sennacrol* and *sennapicrin* (Dragendorff), *sennarhamnetin* (Tschirch and Hiepe), *kaempferol,* $C_{15}H_6O_2(OH)_4$, and its glucoside *kempferin* (Tutin), and a small amount of essential oil.

Kaempferol is a trihydroxy-flavanol and may be extracted from acid aqueous extractions of senna with ether, which also extracts some emodin.

Some observations (published in the *J. P. C.,* Jan., 1874) upon the effect of certain solvents upon senna seem to be of sufficient interest to the pharmacist to deserve being noted. From this it would appear that the activity of senna is injured by heat, alkalies or mineral acids. Alcohol does not dissolve the active principles but extracts made with strong alcohol possess in a high degree the odor and taste of senna, and taken internally, imparts without purging a deep-yellow color to the urine, which the alkalies change to red. The leaves exhausted by alcohol have all their purgative effect, but lose the power of affecting the urine so that an alkaline solution shall color it red. The fact that alcohol removes the odor and taste of senna without affecting its purgative action may sometimes be advantageously applied in cases in which the taste of senna is extremely offensive. L. Siebold, after experimenting with senna leaves washed with alcohol, arrived at the following conclusions: (1) Strong spirit does not remove any of the active principle from senna leaves; (2) the therapeutic action of cathartic acid is assisted by one or more of the constituents yielded by senna to strong alcohol, though these constituents produce no purgative effect when taken alone; (3) senna exhausted by alcohol is a reliable and pleasant purgative, but somewhat weaker in its action than the unexhausted leaves. These conclusions have been confirmed by Maurin (*Rep. Pharm.,* 1921, xxxiii, 228).

When an extract of senna slightly acidified is shaken with ether, the ether solution will give the Bornträger reaction (a pink or red color with ammonia water). If the ether solution is agitated with a saturated solution of nickel acetate, the aqueous layer will develop a red color; on separating and adding potassium hydroxide solution a violet precipitate forms which Beal and Okey state is a characteristic test for senna.

Incompatibles.—Many substances produce precipitates with the infusion of senna, but it does not follow that they are all medicinally incompatible, as they may remove only inert ingredients. Cathartic acid is precipitated by infusion of galls and solution of lead subacetate. Lead acetate and tartar emetic which disturb the infusion, have no effect upon the solution of this substance.

Uses.—Senna was first used as a medicine by the Arabians. It was noticed in their writings as early as the ninth century, and the name itself is Arabic. Like the other cathartics of the anthraquinone series, its action is chiefly upon the lower bowel, and is therefore especially suitable in *habitual costiveness.* It increases the peristaltic movements of the colon by its local action upon the intestinal wall. The tendency to gripe may be obviated by combining it with aromatics or with a saline laxative. The coloring matter of senna is absorbable, and twenty or thirty minutes after the ingestion of the drug it appears in the urine and may be recognized by a red color on the addition of ammonia. It is asserted also that the milk of nursing women acquires purgative properties after the administration of senna.

Dose, one-half to two drachms (2.0–7.7 Gm.).

SENNÆ FRUCTUS. Br.

SENNA PODS

"Senna Pods are the dried ripe fruits of Cassia acutifolia, *Delile,* and of Cassia angustifolia, *Vahl.*" *Br.*

Senna pods, while regarded as an adulterant in the U. S. P. X in that the quantity is restricted, are official in the Br. Pharm. They are described as follows: "About five centimetres long, and from two to two and a half centimetres wide; broadly oblong or somewhat reniform; pale green; brownish in the centre above the seeds; very flat; rounded at the base, slightly mucronate at the apex. Pericarp papery. Seeds obovate-cuneate, flattened. Odor and taste slight." *Br.*

Experiments conducted by Ralph Stockman (*C. D.,* 1915, 156) with fluidextracts of whole senna pods, the pericarp freed from the seeds, and the whole seeds showed that the first gives the most violent purging, severe griping and sometimes sickness and faintness; the second is best, giving satisfactory purgation with least griping; and the last is the weakest purgative and causes considerable pain and griping.

Uses.—They were preferred by the Arabian and medieval physicians of Europe to the leaves, while Pereira states that they are much milder in their operation than the leaflets. This has been explained by the researches of E. F. Salmon, who has found that they contain about 25 per cent. more cathartic acid and emodin than the leaves, but no resinous principle or volatile oil. (*P. J.,* Oct., 1889.) The griping of senna being largely due to the resin, it is *a priori* to be expected that the pods would act more kindly than the leaves. A. W. Macfarlane has found this to be actually the case. From six to twelve pods for the adult, or from three to six for the young or very aged, infused in a claret-glass of cold water, in his experience, act very mildly but very thoroughly upon the whole intestine.

Dose, from one-half to one drachm (2.0–3.9 Gm.).

SERPENTARIA. U. S. (Br.)

SERPENTARIA Serpent.

" Serpentaria consists of the dried rhizome and roots of *Aristolochia Serpentaria* Linné, known in commerce as Virginia Snakeroot, or of *Aristolochia reticulata* Nuttall, known in commerce as Texas Snakeroot (Fam. *Aristolochiaceæ*). Serpentaria contains not more than 10 per cent. of its overground stems and not more than 2 per cent. of other foreign organic matter, and yields not more than 10 per cent. of acid-insoluble ash." *U. S.* " Serpentary Rhizome is the dried rhizome and roots of Aristolochia Serpentaria, *Linn.,* and of Aristolochia reticulata, *Nutt.*" *Br.*

Serpentariæ Rhizoma, *Br.;* Serpentary Rhizome; Virginia Serpentaria; Virginia Snakeroot; Texas Snakeroot; Snakeweed; Pelican-flower, Sangrel; Radix Colubrina; Radix Viperina; Serpentary, Sangree; Serpentaire de Virginie, Couleuvrée de Virginie, *Fr.;* Virginische Schlangenwurzel, *G.*

Many species of Aristolochia have been employed in medicine. Their supposed possession of emmenagogue properties has given origin to the name of the genus. Several of the non-official species are described in Part II.

Aristolochia Serpentaria is a perennial herb, with a short, slender, curved and oblique rhizome and numerous slender roots. Several stems often rise from the same rhizome. They are about eight or ten inches in height, slender, round, flexuose, jointed at irregular distances, and frequently reddish or purple at the base. The leaves are oblong-cordate, acuminate, entire, of a pale yellowish-green color, and supported on short petioles. The flowers proceed from the joints near the root, and stand singly on long, slender, round, jointed peduncles, which are sometimes furnished with one or two small scales, and bend downward so as nearly to bury the flower in the earth or decayed leaves. The tube of the calyx is curved like the letter S, enlarged at the base (ovary) and at its throat, the short limb being obtusely three-lobed. The anthers—six or twelve in number—are sessile, attached to the under part of the stigma, which is fleshy and from three to six-lobed. The fruit is an hexangular, six-celled capsule, containing several small flat seeds. The plant grows in rich shady woods from Connecticut west to Michigan and Missouri and south to Florida and Louisiana. On account of the rather large use of serpentaria the drug is becoming scarcer and attempts at cultivation have been made. (See *Proc. A. Ph. A.,* 1905, liii, p. 275, and *West. Drug.,* xxvii, 775.)

A. hastata (Nuttall.) Duchartre is now considered to be nothing more than a variety of *A. Serpentaria,* from which it differs in having hastate, acute, somewhat cordate leaves, and the lip of the corolla ovate. It flourishes on the banks of the Mississippi, in the Carolinas, and elsewhere. Its root scarcely differs from that of the official plant, and is frequently mixed with it.

A. reticulata Nuttall, known as *Texas Serpentaria* has a root similar to that of *A. Serpentaria* from which numerous short, slender, round, flexuose, jointed stems arise, usually simple, but sometimes branched near the root. The older stems are slightly villous, the young densely pubescent. The leaves, which stand on very short villous petioles, are round or oblong-cordate, obtuse, reticulate, very prominently veined, and villous on both sides, especially upon the veins. From the lower joints of the stem four or five hairy, jointed peduncles proceed, which bear small leafy villous bracts at the joints, and several flowers on short pedicels. The flowers are small, purplish, and densely pubescent, especially at the base and on the ovary. The hexangular capsule is deeply sulcate. This species grows in rich woods in Louisiana, Texas, Arkansas, and Oklahoma.

Description and Physical Properties.—" *Unground Serpentaria.*—Rhizome oblique, subcylindrical, more or less curved, from 10 to 30 mm. in length and from 1 to 2 mm. in diameter; externally dark brown, upper portion with short stem-bases and lower and lateral portions with numerous long, thin, nearly straight, yellowish-brown roots; fracture short; internally yellowish-white; wood with broad, eccentric wedges; odor camphoraceous, terebinthinate; taste bitter, aromatic.

" *Structure.*—Rhizome having an outer layer of epidermal cells; a cortex of from 10 to 15 rows of parenchyma; inner bark sometimes showing strongly lignified bast-fibers, either single or distributed in a more or less interrupted circle; a xylem of broad wood-wedges separated by medullary rays, the latter about 8 cells wide, and with walls strongly lignified and with numerous simple pores; pith eccentric, with polygonal cells with lignified and porous walls; starch in the cells of cortical parenchyma, medullary rays and pith. Stem with an interrupted circle of from 6 to 10 fibro-vascular bundles, a cortex with a prominent continuous ring of strongly lignified cells, and a few non-glandular hairs.

" *Powdered Serpentaria.* — Grayish - brown; starch grains numerous, single and 2- to 4-compound, the individual grains more or less spherical or plano-convex, frequently with a central cleft and from 0.003 to 0.018 mm. in diameter; lignified elements numerous, consisting of tracheæ, wood-fibers, medullary ray cells and pith cells; occasionally a few non-glandular hairs from the stem." *U. S.*

"Rhizome of Aristolochia Serpentaria tortuous and slender, about two centimetres long and three millimetres thick; on the upper surface the remains of slender, aerial stems, and on the under surface numerous wiry interlacing roots, often about seven centimetres long. Both rhizome and roots dull yellowish-brown. Characteristic odor; taste strong, camphoraceous, bitter. Ash not more than 10 per cent. Rhizome and roots of Aristolochia reticulata resemble the foregoing, but are longer and thicker, and the roots are straighter." *Br.*

Holm has published an illustrated article on the pharmacognosy of serpentaria, including the morphology of the stems and leaves. (*M. R.*, xvi, p. 276.)

Virginia Snakeroot is collected for the market in Virginia, North and South Carolina, Tennessee and Georgia. Texas Snakeroot is chiefly gathered in Texas.

Texas serpentaria contains a larger percentage of volatile oil than does the other variety of the drug. The color of serpentaria, which in the recent root is yellowish, becomes brown on keeping.

The roots of *Spigelia marilandica* are sometimes found associated with serpentaria. They may be distinguished by the absence of the terebinthinate odor, and, when the stem and foliage are attached, by the peculiar character of these parts. (See *Spigelia.*)

Constituents.—Serpentaria contains a volatile oil and a bitter principle. The volatile oil which has a camphor-like odor has been investigated by J. C. Peacock (*A. J. P.*, 1891, 257) who finds it consists of about 60 per cent. of a combined ester of borneol boiling at 211° C., sp. gr. 0.9849; the remainder being a terpene (probably pinene) boiling at 157° C., sp. gr. 0.865; a fraction, boiling at from 239° to 240° C., sp. gr. 0.9888 and a small quantity of a bluish-green fluorescent oil which decomposed when distilled even under reduced pressure.

In regard to the bitter principle, which was first described by Chevallier, we have no satisfactory information, although it has been suggested that it may contain some aristolochine.

Aristolochine is a poisonous alkaloid, first isolated by Pohl (*A. E. P. P.*, 1891, xxix, 282), from the seeds of *A. Clematitis* and *A. rotunda.* He obtained it as a yellow crystalline mass, soluble in chloroform, ether, acetone, acetic anhydride, and alcohol, insoluble in petroleum benzin, benzene, and carbon disulphide, almost insoluble in cold water, slightly soluble in hot water. An ultimate analysis gave for its composition $C_{32}H_{22}O_{13}N$. O. Hesse (*P. J.*, 1891, li, 551) found the same alkaloid in *A. argentina* but called it *aristolochic acid.* In the same plant he found four other alkaloids: *aristic acid, aristidinic acid, aristolic acid* and a substance he called *aristolochine* (but different from Pohl's aristolochine). *Aristinic acid* is a resinous substance which has been found in several species including the *A. serpentaria.*

Uses.—Serpentaria is to be classed among the aromatic bitters and in moderate dose acts as a gastric stimulant and is therefore of service in atonic types of *dyspepsia.* In overdose it acts as a local irritant, provoking nausea and griping pains in the bowels, sometimes vomiting and tenesmus. According to Pohl, aristolochine in sufficient dose produces in the higher animals violent irritation of the gastro-intestinal tract and of the kidneys, with death, in coma, from respiratory paralysis.

Dose, fifteen to thirty grains (1 to 2 Gm.).

SEVUM BENZOATUM. Br.

BENZOATED SUET

"Prepared Suet, 1000 *grammes;* Benzoin, in coarse powder, 30 *grammes.* Melt the Suet, add the Benzoin, and maintain at a temperature of 60° C., for one hour, stirring frequently; strain, and stir until nearly cold. In India, Benzoated Suet should be employed in making the official preparations for which Benzoated Lard (Adeps Benzoatus) is directed to be used." *Br.*

It is also official in the N. F. V under the title *Sevum Benzoinatum* (see Part III).

SEVUM PRÆPARATUM. U. S., Br.

PREPARED SUET Sev. Præp. [Mutton Suet]

"The internal fat of the abdomen of the sheep *Ovis aries* Linné (Fam. *Bovidæ*), purified by melting and straining." *U. S.* "Prepared Suet is the purified internal fat of the abdomen of the sheep, Ovis aries, *Linn.*" *Br.*

Sevum, *U. S.* 1890; Sebum Ovillum; Mutton Suet; Prepared Mutton Tallow; Suif de Mouton Purifié, Graisse de Mouton, *Fr.;* Sebum ovile, *P. G.;* Hammeltalg, Talg, Schöpsentalg, Unschlitt, *G.;* Grasso di Moutone, Grasso duro, *It.;* Sebo de carnero, *Sp.*

Suet is the fat of the sheep, taken chiefly from about the kidneys. It is prepared by cutting the fat into pieces, melting it with a moderate heat, and straining it through linen or flannel. In order to avoid too great a heat, the crude suet is sometimes purified by boiling it in a little water. Mutton suet is of a finer consistence, and requires a higher temperature for its fusion, than any other animal fat. It is very white, sometimes brittle, inodorous, of a bland taste, insoluble in water, and nearly so in alcohol. Boiling alcohol, however, dissolves it, and deposits it upon cooling. It consists, according to Chevreul, of stearin, palmitin, and olein, containing approximately 70 per cent. of stearin and palmitin and 30 per cent. of olein. These principles are described under *Olea Fixa.*

Description and Physical Properties.—"A white, solid fat, having, when fresh, a slight characteristic odor and a bland taste. It becomes rancid on prolonged exposure to the air and must not then be used. Prepared Suet is insoluble in water and in cold alcohol. It is soluble in 45 parts of boiling alcohol, in about 60 parts of ether, and slowly dissolves in 2 parts of purified petroleum benzin. From its solution in the latter, when allowed to stand in a stoppered flask, it slowly separates in a crystalline form.

"Prepared Suet melts between 45° and 50° C. and congeals between 37° and 40° C. Saponification value, not less than 193 and not more than 200. Iodine value: not less than 33 and not more than 48. One Gm. of Prepared Suet, dissolved in 50 cc. of hot neutralized alcohol, with a few drops of phenolphthalein T.S. added, requires not more than 0.6 cc. of tenth-normal sodium hydroxide to produce a pink color (*free acid*).

"Preserve in well-closed containers impervious to fat." *U. S.*

"Firm, white, unctuous. Nearly inodorous; taste bland. *Saponification value* 192 to 195; *iodine value* 33 to 46; *acid value* not more than 2.0; melting point 45° to 50° C.; *refractive index* at 60° C., 1.4490 to 1.4510." *Br.*

E. Dieterich examined a large number of samples of mutton and beef suet, and found that they were without exception acid and that neutral suet does not exist. The melting point of mutton suet is between 48.5° and 50.5° C.; that of beef suet, between 47.5° and 48° C. The specific gravity of mutton suet lies between 0.937 and 0.952; that of beef suet, between 0.943 and 0.952. (*A. Pharm.*, 1887, 496.)

SINAPIS NIGRA. U. S.

BLACK MUSTARD Sinap. Nig. [Brown Mustard]

"Black Mustard is the dried ripe seed of *Brassica nigra* (Linné) Koch and *Brassica juncea* (Linné) Cosson and varieties related to these species (Fam. *Cruciferæ*). Black Mustard contains not more than 5 per cent. of other seeds or other foreign organic matter, and yields not less than 0.6 per cent. of volatile oil of mustard (calculated as allyl isothiocyanate)." *U. S.*

Sinapis Nigræ Semina, *Br.* 1898; Black Mustard Seeds; Semina Brassicæ; Moutarde noire, *Fr.;* Semen Sinapis, *P. G.;* Senfsamen, Schwarzer Senf.; Senape nera, *It.;* Mostaza (Semilla de), *Sp.*

The U. S. IX recognized two forms of mustard seed, the so-called black and white mustard, but the latter was dropped at the tenth revision, as it had largely passed out of use as a medicine because of its inferior strength. Linnæus divided the mustards into two genera, *Brassica* and *Sinapis,* and subsequent botanists have greatly disagreed as to whether they should be considered identical or not. The revisers of the U. S. P. have adopted the opinion of Engler and Prantl and of Britton and Brown, that the two genera are distinct. The genus *Sinapis* differs from *Brassica* in that the pods of the former are terminated by a long, flat, sword-like beak, whereas in *Brassica* the beak is cylindrical or conical.

Common black mustard (*Brassica nigra*) is an annual herb, with a stem three or four feet in height, divided and subdivided into numerous spreading branches. The leaves are petiolate and variously shaped. Those arising from the root are large, rough, lyrate-pinnate, and unequally toothed, those on the stem are smooth, and less lobed, and the uppermost are entire and narrow. The flowers are small, yellow, and stand closely together upon pedicels at the upper part of the branches. The pods (siliques) are smooth, erect, nearly parallel with the branches, quadrangular, and furnished with a slender beak; seeds numerous, dark brown.

Brassica nigra is a native of Europe and cultivated in our gardens, and has become naturalized in some parts of this country. Many forms of the plant have been described in horticultural literature. The flowers appear in June. The seeds are kept in the pharmacies, both whole and in the state of very fine powder as prepared by the manufacturers for the table. The latter is sometimes mixed with spices and ground into a smooth paste with water in a mill resembling a paint mill, and then is known as *French mustard* or *German mustard.* The seeds of *Sinapis alba* when treated in the same manner, but without added spices is known as *English mustard.*

Brassica juncea (L.) Coss. (*Sinapis juncea* L.) or *Chinese mustard* is a coarse annual herb indigenous to Asia and extensively grown in India and southern Russia. It possesses large ovate to obovate and lyrate radical leaves with angled or toothed blades and two kinds of stem leaves, the lower toothed and petiolate, the upper oblong to oblong-lanceolate and usually sessile. This species has numerous horticultural varieties.

Under the name of *Sinapis alba,* the U. S. formerly recognized "The ripe seeds of *Sinapis alba* Linné (Fam. *Cruciferæ*), without the presence or admixture of more than 5 per cent. of other seeds or other foreign matter." *U. S. IX.*

Yellow or *white mustard* is a native of Europe and is extensively cultivated, being occasionally spontaneous, in the United States. The commercial supplies are obtained from England, Holland, Germany and California. It is rather smaller than the preceding species. The lower leaves are deeply pinnatifid, the upper sublyrate, and all irregularly toothed, rugged, with stiff hairs on both sides, and pale green. The flowers are in racemes, with yellow petals, and linear, green calycine leaflets. The pods are spreading, bristly, rugged, roundish, swelling in the position of the seeds, ribbed, and provided with a very long ensiform beak.

The seeds of white mustard were officially described as follows: "Sub-globular, from 1.5 to 2.5 mm. in diameter; testa yellowish, nearly smooth; embryo yellowish, oily, with two large cotyledons; inodorous, taste mildly pungent, acrid. The powder is light yellowish or pale brownish-yellow, developing a slight odor when moistened; when examined under the microscope it exhibits numerous tissues of the embryo containing small aleurone grains and a fixed oil, the latter forming in large globules on the addition of hydrated chloral T.S.; fragments of seed-coat comparatively few, nearly colorless, with small, characteristic stone cells and large epidermal cells, the outer walls being mucilaginous. The powder contains few or no starch grains. White mustard does not yield allyl isothiocyanate upon distillation with steam (distinction from *Black Mustard*). White Mustard yields not more than 9 per cent of ash." *U. S. IX.*

For an illustrated monograph on the pharmacognosy of white mustard, see Winton and Moeller, "*Microscopy of Vegetable Foods.*" The only adulterant of white mustard are the seeds of the white Indian *colza,* obtained from *Brassica campestris* Sarson (L.) Prain. They are distinguished in having a more pronounced ridge over the radicle. Under the microscope the seeds have an indistinct epidermis, the collenchymatous subepidermal layer is wanting, and the palisade cells are quite large compared with white mustard.

The seeds of *Brassica ibertifolia* were formerly sold as true white mustard seed. O. Harz examined some obtained from Bavaria, which had been returned by customers to the dealers on account of their bitter and disagreeable taste. He furnishes characteristic microscopical tests for distinguishing the false from the true mustard seed. His statement, however, that powdered white mustard seed when mixed with water is odorless, and that the false gives off a strong odor of essential oil of mustard, would seem to be a good reason, if correct, for preferring the false seed. (*P. J.,* 1887, 478.)

The seeds of *Brassica juncea* afford a very fine mustard flour, and, according to Paul Birkenwald, yield 1.67 parts per hundred of volatile oils, against 1.89 parts per hundred by the true black mustard seed. (*S. W. P.,* 1888.)

Description and Physical Properties.—"*Unground Black Mustard.*—Spheroidal or irregularly spheroidal, from 1 to 1.6 mm. in diameter; testa dark reddish-brown, sometimes yellowish-brown and with a grayish tinge, minutely pitted or reticulate; embryo greenish-yellow or dark yellow, oily, with 2 large cotyledons; odor when dry, slight; on crushing and moistening, very irritating, strongly pungent, characteristic; taste strongly pungent, acrid.

"*Powdered Black Mustard.*—Light brown or greenish-brown; consisting mostly of tissues of the embryo, the cells containing small aleurone grains and a fixed oil, the latter forming in large globules on the addition of chloral hydrate T.S.; fragments of seed-coat conspicuous, with large polygonal, dark yellow areas, enclosing small yellowish stone cells, each of the latter with a dark lumen, few or no starch grains. In the preparation of powdered Black Mustard, a portion of its fixed oil may be removed to facilitate the powdering." *U. S.*

Both white and black mustard afford a powder, which has a somewhat unctuous appearance, and cakes when compressed. This is commonly called *flour of mustard,* or simply *mustard,* and is prepared by crushing and pounding the seeds and then sifting them, the purest flour being obtained by a second sifting. Both the black and the white seeds are used in its preparation. Formerly it was adulterated with wheat flour colored by turmeric, to which cayenne pepper was added to render the mixture sufficiently hot. Pure mustard powder contains very few starch granules, but was formerly adulterated with farinaceous powders; the U. S. P. VIII required that Mustard should conform to the following test: "If 1 Gm. of powdered White (or Black) Mustard be exhausted by slow percolation with alcohol, and the marc mixed with 200 cc. of water and heated to boiling, and if, after cooling, sufficient cold water be added to make the mixture measure 1000 cc., the addition of 4 cc. of tenth-normal iodine V.S. should not produce a dark blue color (limit of *starch*)." *U. S. VIII.* An excellent basic monograph on the pharmacognosy of black mustard is that given by Winton and Moeller in "*The Microscopy of Vegetable Foods.*" Tschirch and Oliva have made a comparative study of the seeds of the *Cruciferæ,* with special reference to the variations found in the seed-coat of the several species of mustard. (*S. W. P.,* xliii, p. 614.) Spaeth gives the results of chemical and microscopical study of the mustards and some of their adulterants in *Ph. Zentralh.,* xlix, p. 698. Carles has also contributed a valuable article on the pharmacognosy of the different mustard seeds and the commercial varieties of mustard flour in *J. P. C.,* 1913, pp. 438 and 535.

Assay.—Methods of assay for mustard seed have been proposed by several authorities (see Service and Regulatory Announcements of U. S. Dept. of Agriculture through *A. J. P.,* 1917, lxxxix, 550; see also *C. U. C. P. Al. J.,* 1916, xxiii, 169). The method of the U. S. P. is based on that of Wehrman, Wegener, Braunworth and Meyer (*A. Pharm.,* 1915, 306) which was awarded the prize of the German Apotheke Verein in 1913. It is as follows: "Place 5 Gm. of Black Mustard, in coarse powder, in a 200 cc. flask, add 100 cc. of water, stopper tightly, and macerate for two hours at about 37° C. Then add 20 cc. of alcohol, and distil about 70 cc. into a 100 cc. graduated flask containing 10 cc. of ammonia T.S. and 20 cc. of tenth-normal silver nitrate. Mix thoroughly, stopper, allow the distillate to stand over night, then heat on a bath of boiling water, cool, add water to make 100 cc., and filter, rejecting the first portions. Acidify 50 cc. of the filtrate, representing 2.5 Gm. of Black Mustard, with about 5 cc. of nitric acid and titrate with tenth-normal potassium thiocyanate, using 2 cc. of ferric ammonium sulphate T.S. as indicator. Each cc. of butyrorefractometer reading (15.5° C.), 74.5 to 0.004957 Gm. of allyl isothiocyanate." *U. S.*

Viehoever, Clevenger and Ewing report that some supplies recently imported from Europe as rape seed but offered for sale as mustard seed represented the seed of *Brassica campestris* *chinoleifera.* According to these authors the volatile oil obtained from this variety of seed is *crotonyl isothiocyanate* which is not a suitable substitute for mustard oil either for condimental, bactericidal or medicinal use. More than 40 per cent. of fixed oil was found which had the general composition of the rape oils. For further details including gross and microscopical features, see *J. Agr. Res.,* 1920, xx, 117, and *J. A. Ph. A.,* 1921, x, 16.

The most common adulteration of black mustard is *charlock,* which is the seeds of *Brassica arvensis* (L.) Ktze. This plant is especially abundant in the northwestern part of the United States and the Dakota mustard contains varying mixtures of brown mustard and charlock. The presence of charlock is very easily determined microscopically by the use of a solution of chloral hydrate which changes the color of the palisade cells to a crimson red.

Constituents.—Mustard seeds yield upon pressure a fixed oil, called *oil of mustard,* of a greenish-yellow color, little odor, and a mild not unpleasant taste; and the portion which remains is even more pungent than the unpressed seeds. The fixed oil of mustard consists of the glycerin compounds of stearic, oleic, and *erucic* or *brassic acid,* $C_{22}H_{42}O_2$, a homologue of oleic acid. Small quantities of *behenic acid,* $C_{22}H_{44}O_2$, also occur in oil of black mustard.

According to F. W. Widmayer (*D. C.,* 1904, 8) the fixed oil from yellow seed is of a greenish-yellow color, that of the brown seed a much darker shade. Both have but little odor and a mild, not unpleasant taste. Mustard seed oil is a semi-drying oil. The analytical data showing maximum and minimum results by M. L. Tolman and L. S. Munson on five samples are as follows: Specific gravity at 15.5° C., 0.9147 to 0.9193; butyrorefractometer reading (15.5° C.), 74.5 to 76.5; index of refraction at 15.5° C., 1.4750 to 1.4762; Maumené number 61.4 to 79.4; specific temperature reaction 130.9 to 190.3; Hübl number, 98.4 to 113.0; saponification value, 173 to 182.8; solidification from −8° to −18° C. Widmayer states that a remarkable feature of this oil is its penetrating or diffusing power; barrels that will hold olive, cotton seed, or petroleum oil, or even new oil or alcohol, invariably leak on being filled with it.

It has been long known that black mustard seeds yield by distillation with water a very pungent volatile oil, containing sulphur. This oil does not pre-exist in the seeds, but is produced by the action of water. Hence the very slight degree of odor in the seeds when bruised in a dry state, and their pungency when water is added. This oil is produced by the decomposition of a compound, *sinigrin* (*potassium myronate*), occurring there. This sinigrin, $C_{10}H_{18}KNS_2O_{10}$, is decomposed under the influence of *myrosin,* an albuminous ferment which is present, yielding C_3H_5CNS (*allyl isosulphocyanate*), $HKSO_4$ (acid potassium sulphate), and $C_6H_{12}O_6$ (glucose). "The aqueous solution of myrosin coagulates at 60° C., and then becomes inactive; hence mustard seed which has been heated to 100° C., or has been roasted, yields no volatile oil, nor does it yield any if powdered and introduced at once into boiling water."

An analogous but different reaction takes place in the case of white mustard; this contains a glucoside called *acrinyl sulphocyanate* (parahydroxy benzylisothiocyanate), C_7H_7OCNS, *sinapine bisulphate,* $C_{16}H_{25}NSO_9$, and sugar, $C_6H_{12}O_6$, an albuminoid substance being formed at the same time.

The analyses of mustard seeds and mustard flour, given in the table below, are by Piesse and Stansell. (*Analyst,* 1880, p. 161.)

Analysis of Brown Mustard.	Whole seeds.	Ground.	
	Cambridge.	Superfine.	Fine.
Moisture	8.52	4.35	4.52
Fatty oil	25.54	36.96	38.02
Cellulose	9.01	3.09	2.06
Sulphur	1.28	1.50	1.48
Nitrogen	4.38	4.94	5.01
Albuminoids	26.50	29.81	30.25
Myrosin and albumin	5.214	6.46	6.78
Soluble matter	24.22	31.14	32.78
Volatile oil	0.047	1.437	1.50
Potassium myronate	1.692	5.141	5.366
Ash	4.98	5.04	4.84

J. U. Lloyd (*A. J. P.,* 1898, p. 433) has proposed standards for black and white mustard seed, mainly directed towards limiting the proportion of starch; the latter is not a constituent of ripe mustard seed, but commercial mustard nearly always contains starch, due to starch-bearing seeds accidentally present in the mustard seed, or to fraudulent admixture.

Uses.—Mustard seeds were formerly sometimes employed in the whole state for their laxative effects. The powder, commonly called simply mustard, in the quantity of from one to two teaspoonfuls (4–8 Gm.), is an efficient and prompt—although unpleasant—stimulant emetic, especially valuable in *narcotic poisoning.* As a condiment mustard acts as a stimulant to the gastric mucous membrane, increasing according to Gottlieb (*A. E. P. P.,* 1894, xxxiii, 261), also the pancreatic secretion. By virtue of this stimulant action it will sometimes relieve obstinate *hiccough.*

But mustard is most valuable as a rubefacient. Mixed with water in the form of a cataplasm, and applied to the skin, it very soon produces redness with burning pain, which in less than an hour usually becomes insupportable. When a speedy impression is not desired, especially when the sinapism is applied to the extremities, the powder should be diluted with varying proportions of wheat flour. Care should be taken not to allow the application to continue too long, as vesication with obstinate ulceration, and even sphacelus, may result. This caution is particularly necessary when the patient is insensible and the degree of pain can afford no criterion of the sufficiency of the action. In making a mustard plaster the admixture of alcohol, vinegar, or other fluid than water, should be avoided as hindering the development of the volatile oil. The volatile oil is powerfully rubefacient, and capable of producing speedy vesication, but certainly is less controllable than is the mustard poultice. (See *Linimentum Sinapis Compositum,* N. F., Part III.) The volatile oil of mustard has been given internally in *colic.* In overdoses it is highly poisonous, producing gastro-enteric inflammation, and probably perverting the vital processes by pervading the whole system. Its odor is perceptible in the blood, and is said to impart the smell of horse-radish to the urine. A *spirit of mustard* may be prepared by macerating, for two hours, 250 parts of powdered black mustard with 500 parts of cold water, then adding 120 parts of alcohol of 86 per cent., and distilling over 120 parts of spirit.

Dose, of mustard seed, one to two drachms (4–8 Gm.).

SODII ACETAS. U. S.

SODIUM ACETATE Sod. Acet.

"Sodium Acetate contains not less than 59.97 per cent. and not more than 62.96 per cent. of $NaC_2H_3O_2$, corresponding to not less than 99.5 per cent. of the crystallized salt [$NaC_2H_3O_2 \cdot 3H_2O$]." *U. S.*

Acetate of Soda; Acetas Sodicus (Natricus), Terra Foliata Tartari Crystallisata, Terra Foliata Tartari; Acetate de Sodium (de Soude), *Fr. Cod.;* Natrium Aceticum, *P. G.;* Natriumacetat, Essigsaures Natron, *G.;* Acetato di Sodio, *It.*

Sodium acetate may be easily prepared by adding crystals of sodium carbonate to acetic acid until it is neutralized, filtering, concentrating the solution, and crystallizing. It is prepared in the large way in the manufacture of crude pyroligneous acid, for the purpose of being decomposed, so as to yield the official acetic acid, by the action of sulphuric acid. The steps of the process by which it is made from the crude acid have been given under *Acidum Aceticum.*

Description and Physical Properties.—"Colorless, transparent, monoclinic prisms, or a granular, crystalline powder. It is odorless, or has a faint, acetous odor. It is efflorescent in warm, dry air. One Gm. of Sodium Acetate is soluble in 0.8 cc. of water and in 19 cc. of alcohol, at 25° C.

"Heated to about 58° C., the salt begins to liquefy. At about 120° C., it becomes anhydrous; at a higher temperature it is decomposed, with the evolution of inflammable, empyreumatic vapors, leaving a residue of sodium carbonate and carbon. An aqueous solution of the salt responds to the reactions, for sodium, and for acetates.

"Dissolve 2 Gm. of Sodium Acetate in 20 cc. of distilled water, and add 2 drops of phenolphthalein T.S.: the pink color produced, if any, is discharged by the addition of 0.1 cc. of tenth-normal sulphuric acid (*alkalinity*). A saturated aqueous solution of Sodium Acetate is not rendered turbid by the addition of sodium bitartrate T.S. (*potassium*). An aqueous solution of the salt meets the requirements of the test for *heavy metals.* An aqueous solution of the salt meets the requirements of the test for *arsenic.*

"**Assay.**—Proceed as directed under the assay for alkali salts of organic acids. Each cc. of half-normal sulphuric acid corresponds to 0.04102 Gm. of $NaC_2H_3O_2$.

"Preserve in well-closed containers." *U. S.*

Sodium acetate, when crystallized, consists of one acetic acid molecule, one atom of sodium and 3 molecules of water.

Uses.—Sodium acetate is diuretic, acting much like potassium acetate, but is rarely used as a medicine. It is employed principally to yield acetic acid by the action of sulphuric acid. In prescribing this salt, the fact, first noticed by Violette, should not be forgotten, that the mixture of equal parts of it and potassium nitrate, if heated, explodes with great violence. (*N. R.,* April, 1873.)

Dose, twenty grains to two drachms (1.3–7.7 Gm.).

SODII ARSENAS. N. F.

SODIUM ARSENATE Sod. Arsen. [Natrii Arsenas, P. I.]

"Sodium Arsenate contains not less than 58.98 per cent. nor more than 61.92 per cent. of anhydrous sodium arsenate (di-sodium ortho-arsenate), corresponding to not less than 99 per cent. of the crystallized salt ($Na_2HAsO_4 \cdot 7H_2O = 312.08$)." *N. F.*

Arsenias Natricus (Sodicus); Sodium Arseniate; Arseniate of Soda; Natrium Arsenicum, *Fr. Cod.;* Arseniate de Sodium Officinal, Arséniate Disodique, *Fr.;* Natriumarsenat, Arsensaures Natron, *G.;* Arseniato bisodico, *It.;* Arseniato sodico, *Sp.*

The U. S. P., of the tenth revision, dismissed both the crystallized and anhydrous sodium arsenate, but they have been admitted to the N. F. Only the anhydrous salt is recognized in the Br. The exsiccated salt is to be preferred as the crystallized arsenate is apt to contain varying proportions of water of crystallization. The N. F. obviates the consequent uncertainty of dosage by inserting an assay provision.

No process for this salt is now official. In that formerly recommended (for details see *U. S. D.,* 19th ed., p. 1127) arsenic trioxide, sodium nitrate and sodium carbonate are heated together. The arsenic trioxide is converted into arsenic acid at the expense of the nitric acid of sodium nitrate, and then combines with the sodium of both salts, carbon dioxide and nitrous fumes being given off. The reaction seems to be as follows:

$$As_2O_3 + 2NaNO_3 + Na_2CO_3 + H_2O = 2Na_2HAsO_4 + N_2O_3 + CO_2$$

Description and Physical Properties.—"Sodium Arsenate occurs is colorless, transparent, monoclinic prisms; odorless. Efflorescent in dry air, and somewhat deliquescent in moist air. *Great caution must be used in tasting it and then only in very dilute solutions.* One Gm. of Sodium Arsenate dissolves in 1.5 cc. of water at 25° C.; also in about 1 cc. of boiling water; slightly soluble in alcohol at 25° C.; nearly insoluble in boiling alcohol.

"When gently heated, the salt loses five molecules of water, and is converted into a white powder. At a higher temperature it loses all of its water of crystallization; when strongly heated, the salt fuses, and at a red heat it is converted into pyroarsenate. Sodium Arsenate responds to the tests for identity and purity prescribed under Sodii Arsenas Exsiccatus when taken in proportionate amount.

"**Assay.**—Dissolve about 0.5 Gm. of Sodium Arsenate, accurately weighed, in 25 cc. of distilled water, heat the solution to 80° C. and add 10 cc. of hydrochloric acid and 3 Gm. of potassium iodide. Allow the mixture to stand for fifteen minutes at 80° C., then cool and titrate it with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.0092985 Gm. of Na_2HAsO_4. Each Gm. of Sodium Arsenate corresponds to not less than 63.44 cc. nor more than 66.59 cc. of tenth-normal sodium thiosulphate.

"Preserve it in well-closed containers." *N. F.*

Anhydrous sodium arsenate has the composition Na_2HAsO_4; in crystals it sometimes contains 12 molecules of water, equal to 53.73 per cent. of its weight. According to the official formula, this salt crystallizes with 7 molecules of water, or 40.39 per cent. "The latter salt loses 40.38 per cent. of its weight when dried at 300° F., becoming anhydrous. An aqueous solution of 12.4 grains of anhydrous arsenate of sodium, acidulated with acetic acid, requires not less than 34 grains of acetate of lead for complete precipitation." *Br.* 1885. If the temperature of a solution of the salt be kept at 30° C., crystals will be deposited which contain 4 molecules of water. J. Lefort examined 10 different samples of the salt, obtained from as many different sources, and found their water of crystallization to vary from 44.05 to 57.45 per cent. (*J. P. C.*, 1880, 487.)

Uses.—Sodium arsenate possesses the therapeutic properties of arsenic. (See *Arseni Trioxidum.*) It is usually exhibited in solution. According to H. N. Moyer it is less irritating to the stomach than the more frequently used potassium arsenite. It is also occasionally employed hypodermically.

Dose, of crystallized sodium arsenate, one-twentieth to one-eighth of a grain (0.003–0.008 Gm.).

Off. Prep.—Sodii Arsenas Exsiccatus, *N. F.*

SODII ARSENAS EXSICCATUS.
N. F. (Br.)

EXSICCATED SODIUM ARSENATE Sod. Arsen. Exsic.

"Exsiccated Sodium Arsenate contains, when dried to constant weight at 150° C., not less than 98 per cent. of Na_2HAsO_4 (185.97)." *N. F.*

Sodii Arsenas Anhydrosus, *Br.;* Anhydrous Sodium Arsenate; Natrium Arsenicum Exsiccatum; Dried Arsenate of Soda; Arséniate de Soude desséché, *Fr.;* Getrocknetes Natriumarsenate, *G.*

"Sodium Arsenate, in crystals, a sufficient quantity. Break the crystals into small fragments, and allow them to effloresce at a temperature between 40° and 50° C., until they are completely disintegrated; then gradually increase the temperature to 150° C., and continue the drying until the product ceases to lose weight. Reduce it to a fine powder, and transfer it to dry, well-closed containers." *N. F.*

"Anhydrous Sodium Arsenate is obtained by exposing to a temperature of 150° C. crystallised sodium arsenate, which may be prepared by treating with water the product of the fusion of arsenious anhydride with sodium nitrate and sodium carbonate. It contains not less than 98 per cent. of pure anhydrous di-sodium hydrogen arsenate, Na_2HAsO_4." *Br.*

For properties see also *Sodii Arsenas.*

Description and Physical Properties.—"Exsiccated Sodium Arsenate occurs as an odorless, amorphous, white powder. It is slightly hygroscopic. *Great caution must be used in tasting it and then only in very dilute solutions.* One Gm. of Exsiccated Sodium Arsenate dissolves in 3.1 cc. of water at 25° C.; also in 1.3 cc. of boiling water; slightly soluble in alcohol at 25° C.; nearly insoluble in boiling alcohol.

"Its aqueous solution (1 in 20) is alkaline to litmus. It imparts an intensely yellow color to a non-luminous flame. An aqueous solution of the salt (1 in 20) yields a white precipitate with barium chloride T.S., and a dark red precipitate with silver nitrate T.S.; both of these precipitates are soluble in nitric acid.

Dissolve 1 Gm. of Exsiccated Sodium Arsenate in 30 cc. of distilled water, render the solution slightly acid to litmus paper by the cautious addition of diluted sulphuric acid, add 20 cc. of a saturated solution of sodium bicarbonate and titrate the liquid with tenth-normal iodine, using starch T.S. as indicator. Not more than 1 cc. of tenth-normal iodine is required (limit of *arsenite*). Add 1 cc. of ammonium sulphide T.S. to 5 cc. of an aqueous solution of the salt (1 in 100); no dark coloration appears (*lead, copper, or iron*).

"**Assay.**—Dissolve about 0.3 Gm. of Exsiccated Sodium Arsenate, dried to constant weight at 150° C. and accurately weighed, in 25 cc. of distilled water, in a glass-stoppered bottle, heat the solution to 80° C. and add 10 cc. of hydrochloric acid and 3 Gm. of potassium iodide. Allow the mixture to stand in the stoppered bottle for fifteen minutes at 80° C., then cool and titrate it with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. It shows, in the dried salt, not less than 98 per cent. of Na_2HAsO_4. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.0092985 Gm. of Na_2HAsO_4. Each Gm. of Exsiccated Sodium Arsenate, previously dried, corresponds to not less than 105.4 cc. of tenth-normal sodium thiosulphate.

"Preserve it in well-closed containers." *N. F.*

"A white powder. Soluble in 6 parts of *water;* slightly soluble in *alcohol* (90 per cent.). Aqueous solution alkaline to *litmus.* Yields the *reactions* characteristic of sodium and of arsenates. When 0.25 gramme is dissolved in 25 millilitres of *water,* and to the solution 3 grammes of *potassium iodide* and 25 millilitres of *hydrochloric acid* are added, not less than 26.3 millilitres of *N/10 solution of sodium thiosulphate* are required to decolorise the iodine liberated. Yields no characteristic *reactions* for lead, copper, iron, aluminium, calcium, carbonates, chlorides, nitrates, or sulphates. Loses not more than 2 per cent. of its weight when dried at 150° C. (limit of moisture)." *Br.*

Uses.—Dried or exsiccated sodium arsenate is useful when it is desired to exhibit the salt in pill form, but differs in no way in its physiological action from sodium arsenate.

Dose, one-fortieth to one-fifteenth of a grain (0.0016–0.004 Gm.).

Off. Prep.—Liquor Sodii Arsenatis, *N. F., Br.;* Liquor Sodii Arsenatis Dilutus, *N. F.*

SODII BENZOAS. U. S., Br.

SODIUM BENZOATE Sod. Benz.

"Sodium Benzoate, when dried to constant weight at 110° C., contains not less than 99 per cent of $NaC_7H_5O_2$." *U. S.* "Sodium Benzoate may be obtained by neutralising benzoic acid with sodium carbonate. It contains not less than 96 per cent. of pure sodium benzoate, $NaC_7H_5O_2$." *Br.*

Benzoas Sodicus; Benzoate of Soda; Benzoate de Soude, *Fr.;* Natrium Benzoicum, *Fr. Cod.;* Natriumbenzoat, Benzoesaures Natron, *G.;* Benzoato di sodio, *It.;* Benzoato sodico, *Sp.*

Sodium benzoate is easily made by adding benzoic acid to a concentrated hot solution of sodium carbonate or bicarbonate until effervescence ceases, and allowing the solution to cool and crystallize. R. Rother, in order to avoid annoyances in the effervescence mixes four ounces of benzoic acid and two and three-fourths ounces of sodium bicarbonate in an evaporating dish with from two to four fluidounces of alcohol; when a uniform mixture is produced, from three to six fluidounces of water are added, heat applied gently, and the powder granulated.

Description and Physical Properties.—"A white, odorless, amorphous, granular or crystalline powder. It is stable in the air. One Gm. of Sodium Benzoate is soluble in 1.8 cc. of water and in 61 cc. of alcohol, at 25° C. One Gm. is soluble in 1.4 cc. of boiling water.

"When heated, Sodium Benzoate fuses, emitting vapors having the odor of benzoic acid, then chars, and finally leaves a residue of sodium carbonate and carbon. It responds to the reactions for sodium, and for benzoates.

"Diluted sulphuric acid added to 5 cc. of an aqueous solution of Sodium Benzoate (1 in 10) produces a voluminous white precipitate of benzoic acid. Dissolve about 1 Gm. of Sodium Benzoate in 10 cc. of distilled water in a separatory funnel, add 10 cc. of diluted sulphuric acid, and shake out the benzoic acid with 2 successive 20 cc. portions of ether. Evaporate the ether solution and test for chlorinated compounds as directed under *Acidum Benzoicum.* Dissolve 2 Gm. of Sodium Benzoate in 20 cc. of hot distilled water, and add 2 drops of phenolphthalein T.S.: the pink color produced, if any, is discharged by the addition of 0.2 cc. of tenth-normal sulphuric acid (*alkalinity*). Acidulate 10 cc. of an aqueous solution of the salt (1 in 50) with hydrochloric acid and filter: the filtrate does not respond to the test for *heavy metals.*

"**Assay.**—Dry Sodium Benzoate to constant weight at 110° C. and proceed as directed under the assay for alkali benzoates and salicylates. Each cc. of half-normal sulphuric acid corresponds to 0.07204 Gm. of $NaC_7H_5O_2$.

"Preserve in well-closed containers." *U. S.*

"A white subcrystalline, or amorphous powder. Inodorous, or with a faint odor of benzoin; taste unpleasant, sweetish, saline. Soluble in 2 parts of *water,* and in 24 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of sodium. An aqueous solution (1 in 10) is slightly alkaline to *litmus,* gives a pale reddish precipitate with *T. Sol. of ferric chloride,* and yields with *diluted hydrochloric acid* a crystalline precipitate of benzoic acid. Loses not more than 4 per cent. of its weight when dried at 110° C. 1 gramme of this dried salt heated to redness till gases cease to be evolved leaves an alkaline residue which, treated with *water,* filtered, and well washed, yields a clear solution requiring for neutralisation not less than 13.7 or more than 13.9 millilitres of *N/2 solution of sulphuric acid.* Yields no characteristic *reactions* for copper, iron, potassium, or carbonates, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million." *Br.*

C. E. Smith (*A. J. P.,* 1917, lxxxix, 576) points out some difficulties likely to be encountered in passing on samples of sodium benzoate for purity and strength.

Uses.—Sodium benzoate is used in the treatment of *rheumatism,* either of the acute or chronic type. Its mode of action in these conditions is apparently similar to that of the salicylates, although it is usually a less efficacious remedy. It has also been used in the treatment of *lithemia* and *gouty conditions* but with less convincing benefit. It is of service also as a urinary antiseptic, but the ammonium salt is generally preferred. Although benzoic acid is a powerful germicide the neutral salts are only feebly so. According to Doepner a 1 per cent. solution of sodium benzoate has only a slight retarding influence upon the growth of the bacteria; on the other hand, Herter (*J. A. M. A.*, 1910, liv) states that one-fifth of one per cent. has a perceptible inhibiting action. It is probable that the strong effects of sodium benzoate as a food preservative are due to a partial liberation of benzoic acid by the acidulous matters of the food stuff to which it is added. It is quite certain that an acid condition of the urine very greatly increases its efficacy as a urinary antiseptic.

Dose, from fifteen to thirty grains (1.0–2.0 Gm.).

SODII BICARBONAS. U. S., Br.

SODIUM BICARBONATE Sod. Bicarb

" Sodium Bicarbonate, when dried to constant weight over sulphuric acid, contains not less than 99 per cent. of $NaHCO_3$." *U. S.* " Sodium Bicarbonate may be obtained by exposing crystals of sodium carbonate to carbon dioxide, or by the interaction of sodium chloride and ammonium bicarbonate. It contains not less than 98.5 per cent. of pure sodium hydrogen carbonate, $NaHCO_3$." *Br.*

Natrium Carbonicum Acidulum; Natrium Hydrocarbonicum; Bicarbonas Sodicus; Bicarbonate of Soda, Saleratus; Soda Saleratus, Acid Sodium Carbonate; Sodium Hydrogen Carbonate; Carbonate Acide de Sodium, Sel de Vichy, *Fr.;* Natrium Bicarbonicum, *P. G.;* Natriumbicarbonat, Doppeltkohlensaures Natron, *G.;* Bicarbonato di sodio, *It.;* Bicarbonato sodico, *Sp.*

Two kinds of sodium bicarbonate were formerly official—one, which is known by the title of this article, and which, to comply with the tests, must not have more than one per cent. of impurity, and the other, " commercial bicarbonate," which must contain at least 95 per cent. of pure bicarbonate. Formerly to obtain a salt which would comply with the official test it was necessary to purify the commercial salt. The U. S. Pharm. 1890 recognized only the purer salt, having dismissed *Sodii Bicarbonas Venalis.* Sodium bicarbonate must now contain 99 per cent. of the pure salt, and it is rarely found below this standard even when sold in grocery stores.

Immense quantities of sodium bicarbonate were formerly imported from Great Britain, but the importation has ceased because of the development of the industry in this country. It is now made of excellent quality by the Pennsylvania Salt Manufacturing Co., at Natrona, Pa., using cryolite as raw material; and by the Solvay Process Co., of Geddes, near Syracuse, N. Y., using the ammonia-soda process; and the Michigan Alkali Co., of Wyandotte, Mich., and the Mathison Alkali Co., of Saltville, Va., from brine.

Description and Physical Properties.—" A white, opaque, odorless powder. It is stable in dry air, but slowly decomposes in moist air. One Gm. of Sodium Bicarbonate is soluble in 10 cc. of water at 25° C. It is insoluble in alcohol.

" An aqueous solution of Sodium Bicarbonate (1 in 20), when freshly prepared with cold distilled water, without shaking, is slightly alkaline to litmus paper. The alkalinity increases upon standing, agitation, or increase in temperature. When heated above 15° C., an aqueous solution of the salt gradually loses carbon dioxide, and at boiling temperature the salt is almost completely converted into normal sodium carbonate. When heated, the salt is decomposed into sodium carbonate, water, and carbon dioxide, and at 100° C., loses about 36.5 per cent. of its original weight. An aqueous solution of the salt responds to the reactions for sodium, and for bicarbonates.

" Dissolve 1 Gm. of Sodium Bicarbonate in 20 cc. of distilled water at 25° C.: it yields a clear and colorless solution, leaving no residue. Heat Sodium Bicarbonate in a test tube: no odor of ammonia is evolved and moist red litmus paper is not colored blue. Dissolve 1 Gm. of the salt without agitation in 20 cc. of distilled water at a temperature not exceeding 15° C., and add 0.2 cc. of normal hydrochloric acid and 2 drops of phenolphthalein T.S.: a red tint does not appear immediately (*carbonate*). An aqueous solution of the salt (1 in 50), mixed with a slight excess of hydrochloric acid, meets the requirements of the test for *heavy metals.*

" Preserve in well-closed containers, in a cool place." *U. S.*

" A white powder, or small, opaque, monoclinic crystals. Taste saline. Soluble in 11 parts of *water.* Yields the *reactions* characteristic of sodium and of bicarbonates. 1 gramme requires for neutralisation not less than 11.7 or more than 11.9 millilitres of *N/1 solution of sulphuric acid.* Yields no characteristic *reactions* for copper, iron, aluminium, calcium, sulphites, or thiosulphates, and not more than the slightest *reactions* for chlorides, sulphates, or ammonium. *Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million. When 1 gramme of Sodium Bicarbonate is dissolved in 20 millilitres of cold *water,* without shaking, and 0.2 millilitre of *N/1 solution of sulphuric acid* and 2 drops of *solution of phenolphthalein* are added, no red color is immediately developed (limit of carbonate). The addition of *T. Sol. of ferric chloride* to the aqueous solution acidified with *hydrochloric acid* causes no red coloration (absence of thiocyanates)." *Br.*

Assay.—" Dry about 3 Gm. of Sodium Bicarbonate over sulphuric acid to constant weight, weigh accurately, mix it with 25 cc. of distilled water, and titrate with normal sulphuric acid, methyl orange T.S. being used as indicator. Each cc. of normal sulphuric acid corresponds to 0.08401 Gm. of $NaHCO_3$." *U. S.*

" 20 grammes of Sodium Bicarbonate are neutralised by 16.7 grammes of Citric Acid, and by 17.8 grammes of Tartaric Acid." *Br.*

The salt furnished by the manufacturers almost always comes up to the requirements of the Pharmacopœias. The presence of carbonate may be known by a decided alkaline taste and reaction, by a cold solution of the salt yielding a precipitate with magnesium sulphate, and by a solution in 40 parts of water affording, without agitation, an orange-colored or reddish-brown precipitate with corrosive sublimate. E. Kuhlmann recommends rosolic acid as the best test for detecting monocarbonate; if a small fragment be placed in a solution of sodium bicarbonate, the liquid remains perfectly colorless even after a quarter of an hour if the salt be pure; but if it contain from one to four per cent. of monocarbonate a rose-red color will be produced after a few moments, and *immediately* in the presence of larger quantities, rapidly changing it to purple-red. (*A. Pharm.,* 1887, p. 72.)

When the solution is exposed to heat, the salt gradually parts with carbon dioxide, and, at the temperature of 100° C., is converted into sesquicarbonate, $Na_2CO_3.NaHCO_3.2H_2O$. At red heat the second equivalent of carbon dioxide is expelled, and the anhydrous carbonate is left.

Sodium bicarbonate of course is incompatible with acids which decompose it with effervescence, and with all salts of metals which produce insoluble carbonates or which possess an acid reaction. Many salts of bismuth magnesium, lithium, lead and zinc liberate CO_2 when brought into contact with sodium bicarbonate. Acetylsalicylic acid, heroin and diacetyl tannin also decompose it, probably on account of the instability of their molecular structure.

Uses.—Sodium bicarbonate is used in medicine solely for the purpose of overcoming hyperacidity either of the stomach, blood, or urine.

As a local remedy it has the great advantage over the basic carbonate of being less irritant to the mucous membrane and for systemic use that it can be given intravenously in large quantities with less danger of hemolysis.

In various types of *dyspepsia* the bicarbonate of soda is probably the most frequently used and one of our most valuable agents. In *hyperchlorhydria* it is useful for its antacid action, although it requires large doses compared to either calcium or magnesium salts. In *gastric ulcer* and other painful conditions, as pointed out by Bastedo (*Am. Med.,* Aug., 1920) its pain relieving effect cannot be attributed entirely to its antacid action.

The second great use for soda is for the correction of the condition commonly known as *acidosis* or *acidemia.* Attention may be called to the incorrectness of this name as the blood never becomes acid in reaction during life; the condition involves a diminution of the alkali reserve, not an actual alteration of the reaction of the blood. The most severe type of acidosis is that which gives rise to the *diabetic coma.* Milder types are seen in the post-anesthetic *nausea,* in certain types of *nephritis* such as that seen after poisoning by mercury bichloride. In these cases large doses are employed. Thus Cary (*J. A. M. A.,* 1921, lxxvi, p. 1393) recommends in diabetic coma the administration of from 25 to 50 Gm. (6 to 13 drachms) in the first two hours, of which part may be given by mouth and the remainder either by rectum or by intravenous injection. As has been shown by Goto (*J. Ex. M.,* 1917, xxv, p. 693), McNider and others soda has the power of protecting the kidney against the irritating effects of certain poisons and is therefore useful in some types of *nephritis* and in the treatment of poisonings by mercury, uranium, etc. It is also employed to alkalize urine in various types of *rheumatic* and *gouty* disorders, but for this purpose usually has no superiority over the citrates which are more agreeable to take. Castellani (*B. M. J.,* 1921, i, p. 338) recommends the use of large doses of sodium bicarbonate in the treatment of *sprue.*

When used for its systemic effect, sodium bicarbonate is least objectionable if administered dissolved in carbonated water which may be flavored to taste.

In pharmacy it is widely employed for making effervescent powders.

Dose, for an adult, from ten grains to a drachm (0.65–3.9 Gm.), taken most conveniently in a glass of carbonic acid water.

Off. Prep.—Tabellæ Sodii Bicarbonatis, *N. F.;* Liquor Sodæ et Menthæ, *N. F.;* Mistura Rhei Composita, *N. F.;* Liquor Sodii Boratis Compositus, *N. F.;* Pulvis Pancreatini, *N. F.*

SODII BIPHOSPHAS. U. S. (Br.)

SODIUM BIPHOSPHATE Sod. Biphos. [Sodium Dihydrogen Phosphate, Monosodium Orthophosphate]

"Sodium Biphosphate, when dried to constant weight at 100° C., contains not less than 98 per cent. of NaH_2PO_4. It contains not more than 15 per cent. of water." *U. S.* "Acid Sodium Phosphate may be obtained by the combination of di-sodium hydrogen phosphate with phosphoric acid. It contains not less than 70 per cent. of pure sodium di-hydrogen phosphate, NaH_2PO_4." *Br.*

Sodii Phosphas Acidus, *Br.;* Acid Sodium Phosphate; Sodium Di-hydrogen Phosphate; Sodium Biphosphate, Monosodium Hydrogen Phosphate.

This salt, which has been introduced into medicine and is found as a commercial article, is sometimes known as *primary sodium phosphate* or *monosodium orthophosphate.* It is prepared by adding the proper molecular proportions of the ordinary disodium orthophosphate and phosphoric acid according to the following reaction:

$$Na_2HPO_4 + H_3PO_4 = 2NaH_2PO_4.$$

This salt is not only used in medicine, but is employed in the manufacture of baking powders in which it plays the part of the acidic element in liberating CO_2 from $NaHCO_3$.

Description and Physical Properties.—"Colorless, transparent crystals or a white, granular, crystalline powder. It is odorless and slightly deliquescent. It is freely soluble in water and practically insoluble in alcohol, chloroform, and ether.

"At 100° C. Sodium Biphosphate loses its water of crystallization (13.04 per cent.); at 210° C., it is converted into disodium dihydrogen pyrophosphate ($Na_2H_2P_2O_7$). At still higher temperatures it is changed into a mixture of sodium metaphosphate ($NaPO_3$) and modifications of sodium metaphosphate. An aqueous solution of Sodium Biphosphate is acid to litmus paper and produces effervescence with sodium carbonate. An aqueous solution of the salt (1 in 20) responds to the reactions for sodium, and for phosphates.

"Dissolve 2 Gm. of Sodium Biphosphate in 40 cc. of distilled water, and add 1 drop of methyl orange T.S. If the solution is pink, it requires not more than 0.3 cc. of normal sodium hydroxide to discharge the pink color (*free acid*). If the solution is yellow, it requires not more than 0.3 cc. of normal sulphuric acid to render it pink (*disodium phosphate*). An aqueous solution of the salt (1 in 10) does not become turbid when rendered slightly alkaline to litmus paper with ammonia T.S. (*aluminum, calcium,* etc.). Dissolve 1 Gm. of the salt in 100 cc. of 1 per cent. hydrochloric acid: a 10 cc. portion of this solution meets the requirements of the test for *heavy metals.* Dissolve 0.1 Gm. of the salt in 10 cc. of diluted sulphuric acid: the solution meets the requirements of the test for *arsenic.* One Gm. of Sodium Biphosphate shows no more *chloride* than corresponds to 0.2 cc. of fiftieth-normal hydrochloric acid, and 0.2 Gm. shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid. Dry about 2 Gm. of the salt, accurately weighed, for one hour at 60° C. Raise the temperature to 100° C., and maintain that temperature until it ceases to lose weight: the loss in weight should not exceed 15 per cent. (*water*).

"Preserve in tightly-closed containers." *U. S.*

It is described in the British Pharmacopœia, as "transparent, colorless, rhombic crystals, or in crystalline powder. Taste saline, acid. Readily soluble in *water,* the solution being acid to *litmus.* Yields the *reactions* characteristic of sodium and of phosphates. 1 gramme dissolved in a mixture of 10 millilitres of *water* and 10 millilitres of *glycerin* requires for neutralisation not less than 5.8 millilitres of *N/1 solution of sodium hydroxide, solution of phenolphthalein* being used as indicator. Yields no characteristic *reactions* for potassium and ammonium, and not more than the slightest *reactions* for sulphates or chlorides. *Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million." *Br.*

Assay.—"Dry about 2 Gm. of Sodium Biphosphate to constant weight at 100° C., weigh accurately, and dissolve in 10 cc. of distilled water, add 10 cc. of a cold saturated solution of sodium chloride, and titrate the solution with normal sodium hydroxide, using phenolphthalein T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.1201 Gm. of NaH_2PO_4. Dry about 0.15 Gm. of the salt to constant weight at 100° C., weigh accurately, dissolve in 10 cc. of distilled water, and neutralize the solution with normal sodium hydroxide (free from chloride), using phenolphthalein T.S. as indicator. Then add 50 cc. of tenth-normal silver nitrate, and thoroughly agitate the mixture. Gradually add reagent zinc oxide in small portions until the mixture is neutral to litmus paper, then dilute the mixture to 100 cc. with distilled water, and filter through a filter which has not been previously moistened. Reject the first 20 cc. of filtrate, collect 50 cc. of the subsequent filtrate, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate to the production of a permanent red tint. Each cc. of tenth-normal silver nitrate corresponds to 0.004002 Gm. of NaH_2PO_4." *U. S.*

Uses.—The acid sodium phosphate is used in medicine for the purpose of increasing the acidity of the urine, especially in certain types of *cystitis.* It may be prepared extemporaneously by treating the neutral phosphate with phosphoric acid; to prepare it extemporaneously about 32 parts of the official phosphoric acid is required for each 100 parts of the neutral sodium phosphate in solution.

Dose, from ten to thirty grains (0.6–2 Gm.).

SODII BORAS. U. S. (Br.)

SODIUM BORATE Sod. Bor. [Borax, Sodium Tetraborate, Sodium Pyroborate]

"Sodium Borate contains not less than 52.32 per cent. and not more than 54.92 per cent. of $Na_2B_4O_7$, corresponding to not less than 99 per cent. of the crystallized salt [$Na_2B_4O_7.10H_2O$]." *U. S.* "Purified Borax may be obtained from native borax; it may also be obtained by boiling native calcium borate with solution of sodium carbonate, and contains not less than 98.9 per cent. of sodium pyroborate, $Na_2B_4O_7,10H_2O$." *Br.*

Borax Purificatus, *Br., P. G.;* Purified Borax; Sodæ Biboras, Biborate of Sodium; Sodium Biborate; Natrium Biboracicum, Boras Sodicus; Natrium Boracicum, *Fr. Cod.;* Borate de Sodium Officinal, Borax Prismatique, Borate de Soude, Bauracon, Sel de Perse, *Fr.;* Borsaures Natron, *G.;* Borato di sodio, Borace, *It.;* Borato sodico, Borax, *Sp.*

Borax was known to the ancients; but its chemical character was first ascertained by Geoffroy in 1732. It exists in nature, and may be obtained by artificial means. It occurs in several localities in Europe, in Peru, and in beds, associated with calcium borate, in the district of Iquique, in the republic of Ecuador. This mineral (*boronatrocalcite*), which has become an article of commerce, and is considerably used as a substitute for borax, contains, according to T. L. Phipson, 34 per cent. of water, 11.95 of soda, 14.45 of lime, 34.71 of boric acid, 1.34 of chlorine, 1.10 of sulphuric acid, 0.60 of silica, and 2 of sand, and may be considered as a compound essentially of one molecule of crystallized sodium borate and two molecules of calcium borate, with two molecules of water. It is said also to contain usually some iodine and bromine. (G. Sims.) Borax has long been known to occur in certain lakes of Thibet and Persia, from which it was obtained by spontaneous evaporation; this impure borax was called in commerce *tincal.*

Several sources of borax have been developed within the limits of the United States. The existence of a borax lake in California was first made known by J. A. Veatch in September, 1856, about 100 miles north of San Francisco. This lake supplied large quantities of borax to commerce up to 1868. More recently attention has been attracted to Searles Lake, in San Bernardino County, where potash salts occur with the borax and soda salts. This is now being worked for both potash and borax by concentration and fractional crystallization.

At present the chief supply of American borax comes from the more easily worked deposits in the sandy deserts, southeast of Pyramid Lake, in Nevada, in the Slate Range district, San Bernardino Co., and Death Valley and Saline Valley, Inyo Co., California. In order to reduce as much as possible the cost of transportation before the present railway facilities, the boraxes of the Pacific coast were made usually of high quality, and the so-called *"boracic acid glass,"* one pound of which is equal to three pounds of ordinary borax, was prepared. For an interesting description of the Slate Range district, see *Chem. News,* 1886, 245. Another important source in California are the *colemanite* (*calcium borate*) deposits twelve miles northeast of Daggett, in the Mojave Desert. This formation (one hundred feet or more in width) has been traced for fully ten miles. The colemanite is readily dissolved by sodium carbonate solution, when the borax crystallizes out.

Borax is also prepared from the boric acid deposits which are found in various volcanic regions of Italy (see *Acidum Boricum*). This acid is neutralized either by adding sodium carbonate to a hot saturated solution or the manufacturer mixes the acid in a solid state with a proper proportion of soda ash, and exposes the mixture to the heat of a reverberatory furnace, provision being made for the collection of a large quantity of ammonia, which is always present in the crude acid and escapes during the process.

Description and Physical Properties.—"Colorless, odorless, transparent, monoclinic prisms, or a white powder. It is efflorescent in warm, dry air. One Gm. of Sodium Borate is soluble in 15 cc. of water and in about 1 cc. of glycerin, at 25° C. One Gm. is soluble in 0.6 cc. of boiling water. It is insoluble in alcohol. When heated, the salt at first loses part of its water of crystallization, then melts, and, when further heated, swells and forms a white, porous mass. At red heat, Sodium Borate loses all of its water of crystallization and fuses to a colorless glassy mass or bead.

"An aqueous solution of Sodium Borate (1 in 20) is alkaline to litmus paper. An aqueous solution of the salt (1 in 20) responds to the reactions for sodium, and for borates.

"An aqueous solution of Sodium Borate (1 in 20) does not effervesce with acids (*carbonate or bicarbonate*). An aqueous solution of the salt (1 in 20) meets the requirements of the test for *heavy metals.* An aqueous solution of the salt meets the requirements of the test for *arsenic.*

"**Assay.**—Dissolve about 5 Gm. of Sodium Borate, accurately weighed, in 100 cc. of distilled water, and titrate the solution with normal hydrochloric acid, methyl orange T.S. being used as indicator. Each cc. of normal hydrochloric acid corresponds to 0.1008 Gm. of $Na_2B_4O_7$.

"Preserve in well-closed containers." *U. S.*

"Transparent colorless crystals, sometimes slightly effloresced, with a weak alkaline reaction. Taste saline, alkaline. Soluble in 25 parts of *water,* and in 1 part of *glycerin;* insoluble in *alcohol* (90 per cent.). Colors flame intensely yellow. Its aqueous solution, acidified with *hydrochloric acid,* turns *turmeric paper* brown. A hot saturated solution, acidified with a mineral acid, deposits, as it cools, crystals of boric acid, the solution of which in *alcohol* (90 per cent.) burns with a green flame. 2 grammes dissolved in *water* require for neutralisation 10.4 millilitres of *N/1 solution of sulphuric acid, solution of methyl-orange* being used as indicator; and if to this neutralised solution an equal volume of *glycerin* is added, 20.8 millilitres of *N/1 solution of sodium hydroxide* are required for neutralisation, *solution of phenolphthalein* being used as indicator. Yields no characteristic *reactions* for copper, iron, or calcium, and not more than the slightest *reactions* for chlorides or sulphates. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Above a red heat it melts into a limpid liquid, which, after cooling, concretes into a transparent solid, called *glass of borax,* much used as a flux in assays with the blowpipe. Commercial borax is used as a flux in metallurgical operations; as the basis of the enamel so much applied to iron utensils, glazed brick, and much china, earthenware, and tiling; in the laundry with starch to impart a gloss to linen; by the meat packers of the United States (1000 tons yearly) as an antiseptic for meat intended for export to countries whose laws permit its presence, and very largely in soaps and toilet preparations and in detergent powders.

Borax has the property of rendering cream of tartar very soluble in water, and forms a combination with it called *soluble cream of tartar.* (See under *Potassii Bitartras.*) R. F. Fairthorne states that borax is more soluble in water if sugar has been added to it. (*A. J. P.,* March, 1881.)

Composition.—Borax has the formula Na_2B_4-

$O_7 + 10H_2O$. It ordinarily crystallizes in monoclinic prisms, and contains ten molecules of water (*prismatic borax*); but a variety of the salt exists which crystallizes in octahedrons, and contains only five molecules of water (*octahedral borax*). The latter is obtained in the artificial production of borax by crystallizing from a concentrated solution at a temperature between 60° and 80° C. When a solution of borax is evaporated at 100° C., the salt is left as a transparent, amorphous, brittle mass, containing four molecules of water. (Schweitzer.) Borax is looked upon as having the following probable composition, $2NaBO_2.B_2O_3.10H_2O$.

Sodium borate (neutral).—A soluble borate may be made by adding boric acid to a hot concentrated aqueous solution of sodium biborate or borax until it has a neutral reaction; crystals separate which have been erroneously described under the name sodium tetraborate. They are transparent, fragile, and glassy; it is found in commerce in glass-like masses. It is soluble in cold water, but more soluble (70 per cent.) in hot water. It is probably a mixture and not a true compound. Sodium metaborate, $NaBO_2H_2O$, is also known as neutral sodium borate and several compounds of this salt with free metaboric acid, HBO_2, are also known but are little used.

Boron is a non-metallic element which was first produced in the elemental condition by Moissau by the use of the electric furnace. It is an amorphous brown powder, sp. gr. 2.45. The so-called *"crystalline boron"* of the older text books was really *aluminum boride*, AlB_2, which separated out during the electric furnace process of purification.

Uses.—The effects of borax upon the animal system are very feeble, Cyon having found that in daily doses of three drachms borax exerts no preceptible influence upon the dog. Nevertheless, in sufficient amount it exerts a depressing influence upon the heart as well as upon the spinal centers, and a number of instances of poisoning from it have been reported. (For fatal case, see Potter, *J. A. M. A.*, 1921, lxxvi, 378.) The symptoms have varied somewhat, but in most if not all the cases there have been great depression of spirits, fall of bodily temperature, a very feeble pulse—rapid or slow—and an erythematous eruption accompanied with much swelling of the parts, and especially affecting the lower extremities, and followed by exfoliation; nausea, violent vomiting, and hiccough have been present in some cases; ecchymoses have been noted; the mind usually remains clear until late in the poisoning, but death has been preceded by coma, with disturbances of the respiration, and involuntary discharges. The continued use of borax has produced *"borism,"* which is characterized by gastric irritation, a peculiar absence of fatty matter and of moisture from the skin, and various skin eruptions, especially eczema, reddish papules with squamous desquamating borders, seborrheic acne, and scarlatiniform plaques.

The only systemic purpose for which borax is at present employed is in the treatment of *epilepsy*, but in a careful test made on a large scale in the epileptic ward of the Philadelphia Hospital, by H. C. Wood many years ago, it was found to have little or no influence upon that disorder, and these unfavorable conclusions have been confirmed by Yoedicke (*Med. Klin.*, 1912, p. 2020), who found that only a small percentage of cases seemed to be benefited by it. McCartney (*T. G.*, Oct., 1920), however, has reported a number of favorable results.

Borax even in saturated solution is not at all germicidal, but it does possess slight antiseptic properties. According to Miquel the antiseptic strength is 1 in 14, which would be approximately a saturated solution at ordinary temperatures. It is widely employed as a wash for *ulcers* and *abscesses*, but especially for inflammatory conditions of the mucous membranes, such as *conjunctivitis, stomatitis, cystitis, vaginitis*, and the like. It is probable that its beneficial action in these conditions is due more to its innocuousness than to its antibacterial powers. Because of its alkalinity it is a valuable detergent, especially for cleansing mucous membranes. It is sometimes of service as a urinary antiseptic for administration by the mouth, especially when the urine is too highly acid; being eliminated unchanged it tends to alkalinize the urine.

Dose, ten to twenty gains (0.65–1.3 Gm.).

SODII BROMIDUM. U. S., Br.

SODIUM BROMIDE Sod. Brom.

"Sodium Bromide, when dried to constant weight at 100° C., contains not less than 98.5 per cent. of NaBr." *U. S.* "Sodium Bromide may be obtained in the same manner as Potassium Bromide, sodium carbonate being used in place of potassium carbonate. When dried at 110° C. it contains not less than 99 per cent. of pure sodium bromide, NaBr." *Br.*

Bromuretum Natricum; Bromure de Sodium, *Fr.;* Natrium bromatum, *P. G.;* Natriumbromid, Bromnatrium, *G.;* Bromuro di sodio, *It.;* Bromuro sodico, *Sp.*

This salt contains a larger proportion of bromine than does potassium bromide, on account of the lower atomic weight of sodium, sodium bromide containing about 77 per cent. of bromine, while potassium bromide contains about 10 per cent. less. It is a trifle more soluble in water and alcohol. It may be made by the same process that is employed for potassium bromide, substituting sodium carbonate for potassium carbonate.

Description and Physical Properties.—"Colorless or white, odorless, cubical crystals, or a white, granular powder. The salt absorbs moisture from the air without deliquescing. One Gm. of Sodium Bromide is soluble in 1.1 cc. of water and in 16 cc. of alcohol, at 25° C.

"When heated to about 760° C., the salt fuses without decomposition, and at a somewhat higher temperature it volatilizes. An aqueous solution of the salt (1 in 10) responds to the reactions for sodium, and for bromides.

"Dissolve 1 Gm. of Sodium Bromide in 10 cc. of distilled water, and add 0.1 cc. of tenth-normal sulphuric acid: no color is produced upon the subsequent addition of a drop of phenolphthalein T.S. even after boiling (*alkali*). Add a few drops of ferric chloride T.S. and 1 cc. of chloroform to 10 cc. of an aqueous solution of the salt (1 in 20), and shake the mixture: the chloroform does not acquire a violet tint (*iodide*). Drop 1 cc. of diluted sulphuric acid on about 1 Gm. of the powdered salt: no yellow color appears at once (*bromate*). A 10 cc. portion of an aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, is not rendered turbid by the addition of 1 cc. of potassium sulphate T.S. (*barium*). A 2 Gm. portion of Sodium Bromide shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid. An aqueous solution of the salt meets the requirements of the test for *heavy metals*.

"**Assay.**—Proceed as directed under the assay for bromides, using about 0.4 Gm. of Sodium Bromide, dried to constant weight at 100° C. and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.01029 Gm. of NaBr. Each Gm. of Sodium Bromide, previously dried, corresponds to not less than 95.7 cc. and not more than 98.3 cc. of tenth-normal silver nitrate.

"Preserve in well-closed containers." *U. S.*

"Small, white, cubic crystals, or a white granular powder, somewhat deliquescent. Taste saline, somewhat bitter. Soluble in 1.5 parts of *water*, and in 16 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of sodium and of bromides. Loses not more than 5 per cent. of its weight when dried at 110° C. 0.5 gramme of this dried salt, dissolved in *water*, requires for complete precipitation not less than 48.1 or more than 48.9 millilitres of *N/10 solution of silver nitrate*. Yields no characteristic *reactions* for copper, iron, aluminium, zinc, calcium, magnesium, potassium, ammonium, carbonates, cyanides, bromates, or iodates, and not more than the slightest *reactions* for chlorides, iodides, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Uses.—The physiological and therapeutic properties of sodium bromide are precisely similar to those of potassium bromide, which see. Because of the depressant effects of potassium on the heart when injected into the blood stream some believe that sodium bromide is preferable in cases of circulatory weakness. It appears to be somewhat less prone to disturb the stomach than the potassium salt and is usually to be preferred.

Dose, ten to sixty grains (0.65–3.9 Gm.).

Off. Prep.—Elixir Sodii Bromidi, *N. F.;* Elixir Bromidorum Trium, *N. F.;* Elixir Bromidorum Quinque, *N. F.;* Elixir Sodii Bromidi, *N. F.;* Elixir Euphorbia Compositum, *N. F.;* Syrupus Bromidorum, *N. F.*

SODII CACODYLAS. U. S.

SODIUM CACODYLATE Sod. Cacodyl.

"Sodium Cacodylate contains not less than 72 and not more than 75 per cent. of $Na(CH_3)_2AsO_2$ with variable amounts of H_2O." *U.S.*

Dimethylarsenas Monosodicus; Natrium Cacodylicum, *Fr. Cod.;* Cacodylate de Sodium, *Fr.;* Kakodylsaüres Natrium, *G.*

This compound is prepared by heating together potassium acetate and arsenic trioxide which yields a distillate containing *cacodyl,* $As_2(CH_3)_4$, and *cacodyl oxide,* $As_2(CH_3)_4O$. This mixture is treated with an oxidizing agent which produces cacodylic acid, $(CH_3)_2AsO.OH$, which is then neutralized with sodium hydroxide, concentrated and crystallized.

For description of cacodylic acid and other cacodylates, see Part II.

Description and Physical Properties.—"White prisms, or a white, granular powder. It is odorless and deliquescent. One Gm. of Sodium Cacodylate is soluble in about 0.5 cc. of water and in about 2.5 cc. of alcohol, at 25° C.

"An aqueous solution of Sodium Cacodylate (1 in 20) is alkaline to litmus paper. Sodium Cacodylate melts in its water of crystallization at about 60° C. and becomes anhydrous at 120° C. It burns with a bluish flame, emitting a garlic-like odor, and to a non-luminous flame it imparts an intensely yellow color. A mixture of a few drops of an aqueous solution of the salt (1 in 100) with 2 cc. of hypophosphorous acid T.S., allowed to stand in a stoppered tube, develops the odor of cacodyl within one hour.

"A solution of 2 Gm. of Sodium Cacodylate in 50 cc. of distilled water requires not more than 0.5 cc. of tenth-normal acid or 1 cc. of tenth-normal alkali to render it neutral, using 2 drops of phenolphthalein T.S. as indicator. No turbidity is produced in 10 cc. of an aqueous solution of the salt (1 in 20) by 1 cc. of calcium chloride T.S., either in the cold or on heating (*mono-methylarsenate*), or in 5 cc. of the solution by 2 cc. of magnesia mixture T.S. within one hour (*arsenate or phosphate*). An aqueous solution of the salt meets the requirements of the test for *heavy metals*. One Gm. of Sodium Cacodylate shows no more *chloride* than corresponds to 0.3 cc. of fiftieth-normal hydrochloric acid. The addition of 5 drops of barium chloride T.S. to 10 cc. of an aqueous solution of the salt (1 in 50), acidulated with 2 drops of hydrochloric acid, produces no turbidity within one-half minute (*sulphate*).

"**Assay.**—Dissolve about 2.5 Gm. of Sodium Cacodylate, accurately weighed, in 30 cc. of distilled water, render the solution neutral to phenolphthalein T.S. if necessary, and then titrate with normal hydrochloric acid, using methyl orange T.S. as indicator. Each cc. of normal hydrochloric acid corresponds to 0.16002 Gm. of $Na(CH_3)_2AsO_2$.

"Preserve in well-closed containers." *U. S.*

Uses.—Although cacodylic acid was employed as a therapeutic remedy by Jochheim in 1864, its popularity as a remedy may be dated from the writings of Gautier (*B. A. M.*, 1899, p. 604), since which time the salts of this acid have been used to a large extent in a number of conditions, chiefly those in which arsenic has been found to be of value.

The physiological and therapeutic effects of arsenic are the properties of arsenous oxide ion, not of the element arsenium: One should not therefore expect an arsenical action from the cacodylates, and as a matter of experimental fact the toxicity of these salts is in no ways comparable to the proportion of arsenium they contain. On the other hand, cacodylic acid is in part slowly demethylized in the system and yields more or less arsenous acid. For this reason the cacodylates are capable of exercising the therapeutic effects of the inorganic forms of arsenic. Heffter (*A. E. P. P.*, xlvi, p. 230) has shown that a small, and not always constant proportion, ranging between two and three per cent. of the ingested dose of the arsenic is split off in the system, and eliminated in an inorganic form. This view is also sustained by the clinical study of Dawes and Jackson. (*J. A. M. A.*, 1907, xlviii, p. 2090.)

The range of demonstrated therapeutic usefulness of cacodylic acid is similar to that of arsenic. Its early popularity was achieved chiefly in the treatment of skin diseases, especially *psoriasis*, and in *tuberculosis*. (See Cleuet, *Gaz. des Hôp.*, 1921, xciv, 1538.) In the latter condition it seems to act precisely as does arsenic, simply by improving the general nutritive state of the patient. There is also much clinical evidence of its value in various forms of *anemia, leukemia, asthma, chronic bronchitis, malaria,* and various other conditions in which arsenic is useful. It is especially employed in those conditions, such as pernicious *anemia,* in which it is desired to give very large doses of arsenic; Dawes (*J. A. M. A.*, 1911) reports a number of cases of this intractable infection which have been apparently cured, one having shown no symptoms for over three years. It has also been employed in *syphilis,* but the experimental investigations of Nichols (*J. A. M. A.*, 1911, lvi, p. 492) seem to demonstrate that it has no direct action upon the spirochetes. It has also been employed in experimental *trypanosomiasis* (see Pflugholt, *M. M. W.*, 1910) with hopeful results. Besides the above conditions, it has been tried in the treatment of *carcinoma, leprosy,* and *pellagra,* but not to sufficient extent to allow of a positive conclusion as to its value. Although, as stated above, it is probable that cacodylic acid possesses no virtues which are not inherent in arsenic, it deserves recognition as a useful remedial agent. Its advantages over arsenous acid lie not merely in the fact of its lower toxicity, but especially in that it can be given hypodermically. If it be reduced in the system and arsenic eventually liberated, this change will not begin until after the remedy has passed the stomach, and probably does not occur to any large extent until after absorption, so that a comparatively large amount of arsenic can be introduced through the alimentary canal with little danger of deranging digestion. When given by the mouth, however, it generally imparts such a strong garlicky odor to the breath that this method of exhibiting the drug is rarely available.

Dose, one-fourth of a grain to two grains (0.016–0.13 Gm.).

Off. Prep.—Ampullæ Sodii Cacodylas, *N. F.*

SODII CARBONAS. Br.

SODIUM CARBONATE

"Sodium Carbonate may be obtained from sodium chloride by interaction with ammonium bicarbonate, ignition, and subsequent crystallisation. It contains not less than 99 per cent. of pure sodium carbonate, $Na_2CO_3,10H_2O$." *Br.*

Carbonate of Soda, Sal Soda, Washing Soda; Natrium Carbonicum, *P. G.;* Carbonas Sodicus, Sal Sodæ; Carbonate Neutre de Sodium Cristallisé Officinal, *Fr. Cod.;* Einfach Kohlensaures Natron, Kohlensaures Natron, *G.;* Carbonate di sodio, *It.;* Carbonato sodico cristalizado, Cristales do Sosa, *Sp.*

There are three forms of sodium carbonate employed in medicine containing various amounts of water of crystallization. The dried sodium carbonate of the Br. represents 95 per cent. of absolute Na_2CO_3, the monohydrated of the U. S. represents about 86 per cent., while the crystalline salt of the Br. represents approximately 37 per cent. The latter compound is a dekahydrate and is the kind usually sold in grocery stores as a water softener, whence the name, *washing soda.*

Sodium carbonate is official in the U. S. P. only as *Sodii Carbonas Monohydratus.*

Native soda, sometimes called *natron,* is found in various parts of the world and exists either in the surface earth, which often exhibits a saline efflorescence, or in solution in small lakes, from which it is extracted by taking advantage of the drying up of the water during the heats of summer. (See *U. S. D.*, 19th ed., p. 1136.)

Sodium carbonate is made from common salt by the older or Leblanc process in two steps; first, converting the salt by sulphuric acid into sodium sulphate, and, then, decomposing the sulphate by calcium carbonate and charcoal at a high temperature, so as to yield sodium carbonate. The chemical reactions may be summarized as follows:

$$2NaCl + H_2SO_4 = Na_2SO_4 + 2HCl$$

$$Na_2SO_4 + CaCO_3 + C_4 = Na_2CO_3 + CaS + 4CO$$

Later a process was put in practice which has given so much satisfaction in its results that it has superseded the process of Leblanc. It is designated the *ammonia-soda* or *Solvay* process, and is based on the fact that when carbon dioxide is passed into a solution of common salt in aqueous ammonia a double decomposition occurs, and the slightly soluble sodium bicarbonate is precipitated:

$$NH_3 + CO_2 + NaCl + H_2O = HNaCO_3 + NH_4Cl$$

From the mother liquor containing the sal-ammoniac, if deemed advisable, the ammonia may by withdrawn by the action of lime, and serve in the renewal of the operation. The sodium bicarbonate is reduced by heat to the carbonate, and the carbon dioxide thus obtained serves to convert the ammonia into the ammonium bicarbonate necessary in the proceeding. The waste product here is calcium chloride, which takes with it all the chlorine of the salt originally used. Therefore if the ammonia-soda process were to replace the Leblanc process, hydrochloric acid and chlorine would have to be made independently, and would become much dearer than at present. To obviate this objection to the ammonia-soda process and to produce hydrochloric acid as one product of the same process, the late Walter Weldon proposed to use magnesia instead of lime in the decomposing of the sal-ammoniac. This would leave magnesium chloride instead of calcium chloride. Steam will liberate hydrochloric acid from the magnesium chloride. This process is carried out practically at Salindres in France, although its economy is not definitely established. Ludwig Mond proposed to freeze out the ammonium chloride from the mother liquors by artificial refrigeration, sublime it, and pass the vapor over magnesia, whereby the hydrochloric acid is retained in combination with the magnesia as magnesium chloride, while the ammonia passes on. The magnesium chloride is then heated in a current of air, when it is split up into chlorine and magnesia.

The reaction between ammonium bicarbonate and sodium chloride, upon which the ammonia process was founded, was first discovered by Dyar and Hemming about 1838, but it was only in 1863 that Ernest Solvay, a Belgian chemist, made it a practical success. The advantages of this method are that the sodium chloride is directly transformed into sodium carbonate, that in the precipitation sodium is the only metal thrown down, and that the preparation is therefore remarkably pure, that the apparatus used is very simple, that the process is inexpensive, great saving of fuel and of labor, and, finally, that no unwholesome gases are diffused in the atmosphere. In this double decomposition between ammonium bicarbonate and sodium chloride only about two-thirds of the chloride undergoes the change. The reaction is limited by another in an inverse direction. Thus, if ammonium bicarbonate and sodium chloride yield sodium bicarbonate and ammonium chloride, these, put together, inversely yield ammonium bicarbonate and sodium chloride. An equilibrium is thus established, and the mixture preserves a constant composition, at the point where the two reactions take place at the same time.

Another source of sodium carbonate was discovered in *cryolite,* a mineral existing in great abundance on the coast of Greenland, and largely imported into America for the manufacture of soda. Cryolite consists mainly of a double aluminum and sodium fluoride, containing in 100 parts 13 of aluminum, 34 of sodium, and 53 of fluorine. Sodium carbonate is obtained by heating cryolite with lime, whereby calcium fluoride is formed, while the sodium and aluminum combine to form a sodium aluminate, a weak salt, which is dissolved out by lixiviation. The soda is converted into carbonate by passing carbon dioxide under pressure through the solution, and the alumina, separated from the soda, becomes insoluble, and is deposited.

Besides the preparation of sodium carbonate, cryolite is employed for other important purposes. Within recent years it has become quite important as a flux for the electrolytic production of aluminum by the Hall and similar processes. (See *Alumen.*) Its only known locality, at least in large amount, is Greenland, where it is found on the southwest coast, near Cape Farewell, existing in beds, of which one is said to be eighty feet thick and three hundred long. It is a handsome mineral, hard, brittle, and translucent, sometimes almost transparent, but generally of a frosty whiteness, which probably suggested its name of *cryolite* or *kryolite,* from the Greek *κρύος, frost.* Though homogeneous in great degree, it exhibits here and there in its substance dark spots, sometimes mere specks, sometimes of considerable size, which appear to be crystalline centers of substances mixed with it at the time of solidification, such as galena, ferrous carbonate, copper and iron pyrites, etc.

Soda-ash is a name given to crude sodium carbonate. It was formerly found in commerce in white or gray masses, and contains about half its weight of foreign salts, consisting of sodium chloride and sodium sulphate. The soda-ash of the modern soda industry is almost pure anhydrous sodium carbonate. Soda-ash is used in soap making, in the glass industry, and in many industries where an alkali is needed as in dyeing and bleaching.

Properties.—" Transparent, colorless, rhombic crystals, efflorescent. Taste strongly alkaline. Soluble in 2 parts of *water.* Aqueous solution strongly alkaline to *litmus.* Free from the impurities enumerated under 'Sodii Bicarbonas.' When heated it liquefies and then dries, losing 62.9 per cent. of its weight. 1 gramme requires for neutralisation not less than 13.8 millilitres of *N/2 solution of sulphuric acid. Lead limit* 10 parts per million. *Arsenic limit*

2 parts per million. 20 grammes of Sodium Carbonate are neutralised by 9.8 grammes Citric Acid, and by 10.5 grammes of Tartaric Acid." *Br.*

Sodium carbonate is incompatible with acids, which decompose it with effervescence, acidulous salts, lime water, ammonium chloride, and earthy and metallic salts.

Uses.—Sodium carbonate may be used to correct excessive acidity either of the alimentary tract or of the general system. For reasons pointed out under sodium bicarbonate, the latter is usually to be preferred to the basic salt. On the basis of some old experiments by Lewaschen many years ago, who asserted that soda markedly increased the liquidity of the bile and diminished the percentage of solids in it, the drug has been largely used in the treatment of *gallstones* and other affections of the biliary passages. While there is considerable clinical evidence as to the value of alkalies in these conditions, their beneficial effect must be attributed to other factors, as it seems to be pretty well established that the alkalies increase neither the quantity nor the alkalinity of the bile (see Glass, *A. E. P. P.*, 1892, xxx).

Fischer's solution, which is largely employed as an intravenous or rectal injection to alkalize the system, is composed of sodium carbonate, crystallized (not the U. S. P. monohydrated which is much stronger) 10 Gm., Sodium Chloride 14 Gm., Water 500 cc. It should not be used hypodermically as it is liable to cause serious sloughing.

Alkaline sodium salts are also employed with advantage, internally and externally, in *skin diseases,* especially those of a papulous and scaly character. A lotion suitable for these cases may be formed by dissolving from two to three drachms of the carbonate in a pint of water. For a bath, from eight to sixteen ounces of the salt may be dissolved in the necessary quantity of water. In recent *burns* without much destruction of the skin, the free application of a saturated solution will usually give immediate relief. When swallowed in an over-dose, it acts as an irritant poison. The best antidotes are the fixed oils, acetic acid, and lemon juice.

Dose, from five to thirty grains (0.32–2.0 Gm.).

SODII CARBONAS EXSICCATUS. Br.

EXSICCATED SODIUM CARBONATE

"Exsiccated Sodium Carbonate is obtained by heating Sodium Carbonate until it loses nearly 63 per cent. of its weight. It contains not less than 95 per cent. of pure anhydrous sodium carbonate, Na_2CO_3." *Br.*

Dried Carbonate of Soda; Exsiccated Sodium Carbonate; Carbonate Neutre de Sodium sec, *Fr. Cod.;* Natrium carbonicum siccum, *P. G.;* Getrocknetes Natriumcarbonat, Entwässerte Soda, *G.;* Carbonato sodico seco, *Sp.*

The dried sodium carbonate (*Natrium Carbonicum Siccum*) of the *P. G. V* contains about 75 per cent. of anhydrous sodium carbonate and corresponds to the formula $Na_2CO_3 + 2H_2O$. This is not as stable a form as the U. S. P. monohydrated salt.

The crystallized sodium carbonate of commerce, known commonly as *washing soda,* contains ten molecules of water of crystallization, and, when heated, readily undergoes aqueous fusion. This "*dekahydrate*" as it is called in the chemical industries is a very unstable compound, losing water spontaneously during its efflorescence, and gaining in actual strength in terms of its alkalinity. The uncertainty of its strength is what led to the adoption of the stable monohydrate in the U. S. P. Upon continuing the heat, the water is driven off, and a white porous mass remains, which is easily reduced to powder. Dried sodium carbonate is in the form of a white powder, and differs in nothing from the crystallized, except in being devoid of water of crystallization. (See *Sodii Carbonas.*) It is officially described as "a whitish powder. Taste strongly alkaline. Yields the *reactions* characteristic of sodium and of carbonates. 1 gramme requires for neutralisation not less than 17.9 millilitres of *N/1 solution of sulphuric acid. Lead limit* 25 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Uses.—This preparation is not used for medicinal purposes. For certain pharmaceutical manipulations it has the advantage not merely of greater concentration but of greater accuracy because of the variable amount of water in the crystalline variety. Exsiccated sodium carbonate is very hygroscopic and must be kept in well closed containers to prevent absorption of moisture and consequent loss of strength. (See *Sodii Carbonas Monohydras.*)

Dose, two to ten grains (0.13–0.65 Gm.) may be given three times a day, in the form of pill prepared with soap and aromatics.

SODII CARBONAS MONOHYDRATUS. U. S.

MONOHYDRATED SODIUM CARBONATE

Sod. Carb. Monohyd.

"Monohydrated Sodium Carbonate, when rendered anhydrous by gentle ignition, contains not less than 99.5 per cent. of Na_2CO_3." *U. S.*

Preparation.—This salt was introduced into the U. S. P., upon the recommendation of Coblentz and Frerichs, on account of its much greater stability when compared with sodium carbonate; it contains but one molecule of water of crystallization, while the ordinary carbonate contains ten; as it is almost impossible to keep the carbonate without efflorescing, it became difficult to use it for chemical or pharmaceutical purposes without previously determining the quantity of water present. Coblentz ascertained by experiment that by exposure in an open vessel, monohydrated sodium carbonate gained the first week but 0.14 per cent. of moisture, this increased to only 0.16 per cent. by the second week. It is prepared by heating and crystallizing sodium carbonate at a temperature above 35° C. As it can be prepared commercially at a low price of excellent quality and is in the form of granular crystals its introduction into the Pharmacopœia has proved a great convenience. It may be used in the place of sodium carbonate.

Description and Physical Properties.—"A white, odorless, crystalline, granular powder. When exposed to the air, under ordinary conditions, it absorbs only a slight percentage of moisture. When exposed to warm, dry air at or above 50° C., the salt effloresces, and at 100° C. becomes anhydrous. One Gm. of Monohydrated Sodium Carbonate is soluble in 3 cc. of water, and in 7 cc. of glycerin, at 25° C. One Gm. is soluble in 1.8 cc. of boiling water. It is insoluble in alcohol.

"An aqueous solution of Monohydrated Sodium Carbonate (1 in 10) is strongly alkaline to litmus paper and to phenolphthalein T.S., and responds to the reactions for sodium, and for carbonates.

"An aqueous solution of Monohydrated Sodium Carbonate (1 in 50), mixed with a slight excess of hydrochloric acid, meets the requirements of the test for *heavy metals.* Weigh accurately about 2 Gm. of Monohydrated Sodium Carbonate and heat it in a crucible at 110° to constant weight: the loss is not less than 10 per cent. and not more than 15 per cent. (*water*).

"**Assay.**—Transfer the anhydrous sodium carbonate obtained in the foregoing test to a flask with the air of 50 cc. of distilled water and titrate with normal sulphuric acid, methyl orange T.S. being used as indicator. Each cc. of normal sulphuric acid corresponds to 0.05301 Gm. of Na_2CO_3.

"Preserve in well-closed containers." *U. S.*

Uses.—Monohydrated sodium carbonate can be used for the same purposes that sodium carbonate can, in the proportion of 1 of the former to 2.3 of the latter. (See *Sodii Carbonas.*) It contains approximately 86 per cent. of Na_2CO_3 against the 95 per cent. of the dried salt of the Br.

Dose, two to ten grains (0.13–0.65 Gm.).

SODII CHLORIDUM. U. S., Br.

SODIUM CHLORIDE Sod. Chlorid.

"Sodium Chloride, when dried to constant weight at 110° C., contains not less than 99 per cent. of NaCl." *U. S.* "Sodium Chloride, NaCl, may be obtained by purifying common salt." *Br.*

Chloruretum Sodicum, Sal Commune, s. Culinare; Table Salt; Muriate of Soda, Sea Salt, Salt; Chlorure de Sodium Officinal, Sel Commun, Sel marin, *Fr.;* Natrium Chloratum, *P. G.;* Natriumchlorid, Chlornatrium, Kochsalz, *G.;* Chloruro di sodio, Sal commune, *It.;* Cloruro sodico, Sal comun, *Sp.*

This mineral production, so necessary to mankind, is universally distributed over the globe, and is the most abundant of the native soluble salts. Most animals have an instinctive relish for it, and from its frequent presence in the solids and fluids of the animal economy, it may be supposed to perform an important part in assimilation and nutrition.

Common salt exists in nature either in the solid state or in solution. In the solid state, called *halite, rock salt, fossil salt,* or *sal gemmæ,* it is often found forming extensive beds, and even entire mountains, from which it is extracted in blocks or masses by mining operations. Its geological position is very constant, it occurring almost invariably in secondary formations, associated with clay and gypsum. In solution it exists in certain springs and lakes, and in the waters of the ocean. The principal salt mines are found in Poland, Hungary, and Russia; in various parts of Germany and Austria, particularly the Tyrol; in Cheshire, England; in Spain; in various parts of Asia and Africa; in Turk's island near St. Domingo; and in Peru and other countries of South America. There are but few mines in the United States where rock salt has been produced—in Louisiana, in Kansas, and in the western part of the State of New York; but there are numerous salt springs, which either flow naturally or are produced artificially by sinking wells to various depths in places where salt is known to exist. These are found principally in Missouri, Kentucky, Illinois, Ohio, Michigan, Pennsylvania, Virginia, West Virginia, and New York. Much commercial salt is obtained from the water of the Great Salt Lake in Utah, which contains nearly 25 per cent. of sodium chloride. California is the only one of the United States in which sea water is utilized for salt production by solar evaporation; this is done extensively at San Diego Bay.

The salt is obtained from these various sources by evaporation. Sometimes solar heat is used and sometimes artificial heat is employed.

The size of the crystals, known as the grain of the salt, is influenced by the temperature of the evaporation and by the presence of foreign materials, some of which are purposely added to produce fine crystals.

Rock salt is always transparent or translucent; but it often exhibits various colors, such as red, yellow, brown, violet, blue, etc., which are supposed to be derived from iron and manganese.

Extraction.—Mines of salt are worked in two ways. When the salt is pure, it is merely dug out in blocks and thrown into commerce. When impure, it is dissolved in water, and extracted afterwards from the solution by evaporation. When the salt is naturally in solution, the mode of extraction depends upon the strength of the brine and the temperature of the place where it is found. When the water contains from 14 to 15 per cent. of the salt, it is extracted by evaporation in open pans or vacuum pans provided with crystallizing boxes. From weaker solutions, however, the salt is obtained in a different manner. If the climate be warm, it may be procured by spontaneous evaporation, effected by the heat of the sun; if temperate, by a peculiar mode of evaporation, to be mentioned presently, and the subsequent application of artificial heat.

Sea water is a weak saline solution, containing approximately 2.7 per cent. of common salt, (see under *Aqua*), which is extracted by the agency of solar heat in warm countries. Salt thus obtained is called *bay salt.* The extraction is conducted in Europe principally on the shores of the Mediterranean, the waters of which are saltier than those of the open ocean. The mode in which it is performed is by letting the sea water into shallow dikes, lined with clay, and capable, after having been filled, of being shut off from the sea. In this situation the heat of the sun gradually concentrates the water, and the salt is deposited. In temperate climates, weak brines are first concentrated in buildings called *graduation houses.* These are rough wooden structures open on the sides, ten or eleven yards high, five or six wide, and three or four hundred long, and containing an oblong pile of brushwood somewhat smaller than the building itself. The brine is pumped up into troughs full of holes, placed above the brushwood, upon which it is allowed to fall, and in its descent, it becomes minutely divided. This operation, by greatly increasing the surface of the brine, promotes its evaporation; and, being repeated several times, the solution is at last brought to the requisite degree of strength to permit of its final concentration in iron boilers by artificial heat.

A very interesting and valuable article describing the American salt industry, well illustrated with photographs, will be found in the *American Food Journal* for December, 1916.

It usually crystallizes in cubes; but by quiet evaporation it often assumes the form of hollow quadrangular pyramids, or hopper-shaped crystals, consisting of an aggregation of cubes. When perfectly pure sodium chloride is permanent in the air but most of the commercial salt is more or less hygroscopic because of the presence of magnesium chloride.

The common salt of commerce, besides pure sodium chloride, usually contains traces of insoluble matter, and usually small amounts of calcium and magnesium sulphates and calcium and magnesium chlorides. This kind of salt, which is used for culinary and for industrial purposes, is usually damp from the hygroscopic character of the calcium and magnesium chlorides present. To overcome this tendency and produce what is called "free running" salt, for use in table salt shakers, several forms of special table salt have appeared upon the market. In some of these a small amount of foreign matter, as a moisture absorbent, is present. For this purpose calcium phosphate, magnesium carbonate and starch have all been used. In some varieties the same end is attained by the purification of the salt to eliminate these hygroscopic constituents. It follows, therefore, that neither culinary salt nor table salt may be used for U. S. P. sodium chloride because of the uncertainty of their composition and the likelihood of some substances being present which would interfere with the official or medicinal uses for which the pharmacopœial article is intended.

Description and Physical Properties.—"Colorless, odorless, transparent, cubical crystals, or a white, crystalline powder. It is usually slightly hygroscopic. One Gm. of Sodium Chloride is soluble in 2.8 cc. of water, and in 10 cc. of glycerin, at 25° C. One Gm. is soluble in 2.7 cc. of boiling water. It is slightly soluble in alcohol.

"When heated somewhat above 100° C. the salt decrepitates. At higher temperatures it fuses, and is slowly volatilized and partly decomposed. An aqueous solution of the salt (1 in 20) responds to the reactions for sodium, and for chlorides.

"An aqueous solution of Sodium Chloride (1 in 10) is neutral to litmus paper. An aqueous solution of Sodium Chloride meets the requirements of the test for *heavy metals.* Separate portions of 10 cc. each of an aqueous solution of Sodium Chloride (1 in 100) after the addition of 1 cc. of ammonia T.S. show no immediate turbidity upon the addition of ammonium oxalate T.S. (*calcium*), or of sodium phosphate T.S. (*magnesium*). Digest 2 Gm. of the finely powdered salt for three hours with 25 cc. of warm alcohol, cool the mixture, and remove the undissolved salt by filtration. Evaporate the filtrate to dryness, dissolve the residue in 5 cc. of distilled water, add 1 cc. of chloroform, and cautiously introduce, drop by drop, with constant agitation, chlorine T.S. which has been diluted with twice its volume of distilled water: the chloroform does not acquire a violet, yellow, or orange color (*iodide or bromide*).

"**Assay.**—Proceed as directed under the assay for chlorides, using about 0.25 Gm. of Sodium Chloride, dried to constant weight at 110° C. and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.005846 Gm. of NaCl.

"Preserve in well-closed containers." *U. S.*

"Small, white, crystalline grains, or transparent, cubic crystals, free from moisture. Taste saline. Soluble in 3 parts of *water.* Yields the *reactions* characteristic of sodium and of chlorides. Yields no characteristic *reactions* for potassium, bromides, or iodides, and not more than slight *reactions* for calcium, magnesium, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million. 20 millilitres of an aqueous solution (1 in 20) are not immediately colored blue by 0.5 millilitre of *solution of potassium ferrocyanide* (limit of iron)." *Br.*

S. Hill (*Ph. Post.*, 1912, p. 37) states that the flame test for potassium in sodium chloride is unreliable, especially as a great deal of the blue glass gives fallacious results owing to its unsuitability. He recommends the use of *Koevenagel's reagent of cobalt sodium hexanitrite,* which produces a yellow precipitate in potassium solutions as dilute as 1-2000.

Sodium Chloride is decomposed by several of the acids, particularly sulphur and nitric, which disengage vapors of hydrochloric acid; by potassium carbonate with the assistance of heat; and by silver nitrate and mercurous nitrate. In contact with iron, in the presence of air and moisture, it undergoes decomposition. It is decomposed by steam excessively heated, with the escape of hydrochloric acid and an alkaline residue. Several varieties of common salt are distinguished in commerce, as *stored salt, fishery salt, bay salt,* etc.; but they are characterized by the size and compactness of the grains, and not by any difference in composition.

Sodium chloride is incompatible with mercurous, lead, and silver salts with the formation of the corresponding insoluble metallic chloride.

Uses.—Although sodium chloride, like other salines, is capable of exercising a diuretic and cathartic action, because of its rapid diffusibility it is much inferior to many other substances. Common salt has for many years been a household remedy in the treatment of *hemoptysis* in doses of one teaspoonful (3.9 Gm.) taken dry. The observations of Belden (*Z. E. P. T.,* 1909, vii, p. 290) lend support to this employment; he found that although when mixed with the blood outside of the body it had no effect, when administered either by the stomach or by injection it increased the coagulability of the blood. He believed the effect to be due to alteration in the concentration of the blood. Externally applied in solution it is stimulant and may be used either locally or generally. Locally it has been employed in the form of fomentations in *sprains* and *bruises.* Salt baths are used for their tonic and exciting effect in various diseases, especially when attended with weakness of the circulation. A pound of salt to four gallons of water forms a solution of about the strength of sea water and suitable for a bath. (See also under *Aqua.*) Because of its physiological inertness sodium chloride is the substance generally preferred to increase the density of water when for any reason it is desired to inject that fluid directly into the vein (see *Liquor Sodii Chloridi Physiologicus*).

The uses of common salt in domestic economy as a condiment and an antiseptic are well known.

Off. Prep.—Liquor Sodii Chloridi Physiologicus, *U. S.;* Sal Carolinum Factitium, *N. F.;* Sal Carolinum Factitium Effervescens, *N. F.;* Sal Kissingense Factitium, *N. F.;* Sal Kissingense Factitium Effervescens, *N. F.;* Sal Vichyanum Factitium, *N. F.;* Sal Vichyanum Factitium Effervescens. *N. F.*

SODII CITRAS. U. S.

SODIUM CITRATE Sod. Cit.

"Sodium Citrate contains not less than 98 per cent. of $Na_3C_6H_5O_7.2H_2O$." *U. S.*

Citrate of Soda; Citras Sodicus; Citrate de Soude, *Fr.;* Natrium Citricum; Natriumcitrat, Citronsaures Natron, *G.*

The official salt is the normal salt of citric acid and sodium, there being three possible combinations owing to the tri-fold basicity of citric acid. It may be made by adding to a hot aqueous solution of 59 parts of citric acid an aqueous solution of 53 parts of monohydrated sodium carbonate, neutralizing, evaporating, and crystallizing.

Description and Physical Properties.—"Small crystals or a white, granular powder. It is odorless, and has a cooling, saline taste. One Gm. of Sodium Citrate is soluble in 1.3 cc. of water at 25° C. and in 0.6 cc. of boiling water. It is insoluble in alcohol.

"When heated to about 150° C., the salt loses all of its water of crystallization; on ignition at a red heat, it carbonizes and emits inflammable gases which have a very pungent, acrid odor, and a residue remains which is alkaline to litmus paper and strongly effervesces with acids. An aqueous solution of the salt (1 in 20) responds to the reactions for sodium, and for citrates.

"An aqueous solution of Sodium Citrate (1 in 20) is slightly alkaline to litmus paper, but is not reddened by 1 drop of phenolphthalein T.S. To a solution of 1 Gm. of Sodium Citrate in 2 cc. of distilled water, add 1 cc. of potassium acetate T.S. and 1 cc. of acetic acid: no crystalline precipitate forms (*tartrate*). An aqueous solution of Sodium Citrate meets the requirements of the test for *heavy metals.* An aqueous solution of the salt meets the requirements of the test for *arsenic.*

"**Assay.**—Proceed as directed under the assay for alkali salts of organic acids. Each cc. of half-normal sulphuric acid corresponds to 0.04902 Gm. of $Na_3C_6H_5O_7.2H_2O$.

"Preserve in well-closed containers." *U. S.*

Uses.—Sodium citrate, like the potassium salt, is oxidized in the system and appears in the urine in the form of a carbonate, and may therefore be used to overcome excessive acidity of the urine. Lichtwitz (*Th. M.,* 1911, xxv, p. 81) recommends it especially in the treatment of *diabetic acidosis* instead of the carbonates. When added to the blood outside of the body it prevents coagulation, presumably by the formation of non-ionizing calcium citrate. In the same way it prevents the curdling of milk by rennin, the sodium caseinate which is formed by this ferment after the addition of the citrate being soluble. According to Robertson and Burnett (*J. P. Ex. T.,* 1912, lix), when administered in large doses to mammals it causes severe symptoms by depriving the tissues of ionizable calcium. While it has been experimentally shown that the administration of sodium citrate by the mouth may delay the coagulability of the blood, it is improbable that any severely toxic symptoms can be caused by its oral administration. Leone (*Rif. M.*, 1922, xxxviii, p. 312) denies the commonly accepted view that the drug is capable of retarding coagulation when given by the mouth, although he finds that the intravenous injection greatly delays, or in sufficient quantity entirely prevents, coagulation of the blood.

As an anti-coagulant sodium citrate is used very largely in transfusion of blood from one individual to another. For the same reason Steel (*J. A. M. A.*, 1921, lxxvi, p. 429) has recommended it in *thrombo-angiitis obliterans* or Burger's disease; he gives intravenously 250 cc. (8½ fluidounces) of a 2 per cent. solution every other day.

Sodium citrate may be used for the various purposes to which potassium citrate is put (see *Potassium Citrate*), but is probably somewhat less efficient as a diuretic or diaphoretic. It is widely employed in the modification of cow's milk for infant feeding for the purpose of preventing the formation of large hard curds. For this purpose from one to two grains of the salt may be added to each ounce of milk used in the mixture. It has also been highly lauded by Weaver (*New Orleans Med. and Surg. Journ.*, lxxi, 181) in the treatment of *pneumonia.* Wright reported remarkable results from its use as a local application for *furunculosis. Wright's solution* consists of sodium citrate, 2 grains, sodium chloride, 20 grains, water, 1 ounce; cotton saturated with this solution is placed over the boil and covered with waxed paper to prevent evaporation.

Dose, fifteen to sixty grains (1.0–3.9 Gm.).

SODII CITRO-TARTRAS EFFERVESCENS. Br.

EFFERVESCENT SODIUM CITRO-TARTRATE

"Sodium Bicarbonate, in powder, 510 *grammes;* Tartaric Acid, in powder, 270 *grammes;* Citric Acid, in powder, 180 *grammes;* Refined Sugar, in powder, 150 *grammes.* Mix the powders thoroughly; place the mixture in a dish or pan of suitable form heated to between 90° and 105° C. When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 55° C. The product weighs about one thousand grammes." *Br.*

The object of this combination is to furnish an effervescing powder, for making extemporaneous saline mixtures, in a convenient and portable form. As the water has been driven off by heat, no reaction takes place until dissolved in water, when the two acids combine with the soda of the bicarbonate to produce sodium tartrate and citrate, and the carbon dioxide escapes with brisk effervescence. It is in this form that the preparation is intended to be used.

It may be mixed with unpleasant salines whose taste it hides by effervescence. In full dose it has a laxative action similar to that of Seidlitz powders.

Dose, one to two drachms (3.9–7.7 Gm.), which may be taken in a small wineglassful or more of water, and repeated occasionally as required.

SODII GLYCEROPHOSPHAS. N. F.

SODIUM GLYCEROPHOSPHATE Sod. Glycerophos. [Sodium Glycerinophosphate]

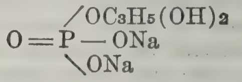
"Hydrated Sodium Glycerophosphate containing not less than 68 per cent. of the anhydrous salt ($Na_2C_3H_7PO_6$ or $C_3H_5(OH)_2PO_4\text{-}Na_2 = 216.11$)." *N. F.*

Natrium Glycerophosphoricum; Glycerophosphate de Soude, *Fr.;* Glycerinphosphorsaüres Natrium, *G.*

Sodium glycerophosphate which formerly existed as a pasty mass can now be found in commerce in solid plates or scales which renders it more convenient for pharmaceutical use. Sodium glycerophosphate has been made by two methods. One is by treating glycerophosphoric acid with sodium hydroxide in a manner similar to the process for calcium glycerophosphate. This method affords a salt of alpha-glycerophosphoric acid. The other method is by heating monosodium phosphate with two molecular proportions of glycerol and hydrolyzing the resulting diglyceryl ester with sodium hydroxide. The first reaction is as follows:

$$NaO.PO.(OH)_2 + 2C_3H_8O_3 = NaO.PO(OC_3H_7O_2)_2$$

A considerable amount of *sodium betaglycerophosphate* crystallizes out at first. This constitutes the official salt. The liquor from which no further amount of salt will crystallize constitutes the *liquid sodium glycerophosphate* of commerce. The official sodium glycerophosphate is the normal salt having the following structural composition, exclusive of water of hydration:



$$O = P \begin{cases} OC_3H_5(OH)_2 \\ ONa \\ ONa \end{cases}$$

Description and Physical Properties.—"Sodium Glycerophosphate occurs as white monoclinic plates or scales, or as a white powder, having a saline taste; odorless. It is very soluble in cold or hot water; nearly insoluble in alcohol.

"An aqueous solution of the salt (1 in 20) is alkaline to litmus and to phenolphthalein T.S. When strongly heated the salt is decomposed, evolving inflammable vapors, and at a red heat is converted into sodium pyrophosphate.

"Dissolve 1 Gm. of Sodium Glycerophosphate in 10 cc. of distilled water and add 3 drops of phenolphthalein T.S.; the red color produced is discharged by the addition of 1.5 cc. of tenth-normal sulphuric acid (*free alkali*). An aqueous solution of the salt does not respond to the Test for heavy metals. Add an equal volume of cold ammonium molybdate T.S. to 10 cc. of an aqueous solution of the salt (1 in 20); no precipitate is formed within one hour (*phosphates*). On heating this mixture a yellow precipitate is formed. Triturate 1 Gm. of the salt with 20 cc. of dehydrated alcohol, filter the mixture, evaporate the filtrate on a water-bath and dry the residue for one hour at a temperature not exceeding 70° C.: the weight of this residue does not exceed 0.01 Gm. (*alcohol-soluble impurities*).

"**Assay.**—Dissolve about 3 Gm. of the salt, accurately weighed, in 30 cc. of distilled water and titrate with half-normal hydrochloric acid, using methyl orange T.S. as indicator. Each cc. of half-normal hydrochloric acid used corresponds to 0.10805 Gm. of $Na_2C_3H_7PO_6$. Each Gm. of Sodium Glycerophosphate corresponds to not less than 6.29 cc. of half-normal hydrochloric acid." *N. F.*

Uses.—The glycerophosphates have been used in medicine on the supposition that being more nearly allied chemically to the form in which phosphorus is found in the body, they would be more easily utilized in conditions of depraved phosphorus nutrition and thereby aid in the upbuilding of nerve strength. It seems well established that when taken by the mouth they are absorbed unchanged but, according to Marfori (*A. E. P. P.*, Schmiedeberg Festsch., 1908, p. 378), when injected subcutaneously they are rapidly excreted by the kidneys. The glycerophosphoric acid absorbed from the alimentary tract is retained for some days but is slowly decomposed in the body, being eliminated through the urine as inorganic phosphate. It is probable that the system is capable of utilizing a portion of the glycerophosphoric acid, synthesizing from it the complex organic bodies in which phosphorus exists in the tissues. But the same thing is true of sodium phosphate. Whether glycerophosphate has any higher nutritive value than inorganic phosphates is extremely doubtful. Forbes (*Ohio Technical Bull.* No. 6, 1914), in an elaborate research upon swine, reaches the conclusion that there is no fundamental differences in the nutritive values of the glycerophosphates and phosphates, except that the former are less likely to disturb the digestive tract. In a review of the literature on this subject for the Council on Pharmacy and Chemistry, Marshall (*J. A. M. A.*, 1915, lxiv, p. 573) concluded "that organic phosphorus is of no more value as a food than inorganic." Granting this be true, however, does not necessarily disprove their therapeutic utility. It is possible to conceive that the unbroken molecule of glycerophosphoric acid, circulating in the blood, may in some way exercise a stimulating action on the metabolism of the central nervous system. While there is considerable clinical evidence of the usefulness of the glycerophosphates in various conditions of depraved metabolism, such as *neuralgia, neurasthenia, senility, Graves's disease, etc.*, the testimony is not unanimous. We must regard, therefore, the question of value of sodium glycerophosphate as a remedy in conditions of general debility, as still *sub judice*. It has the advantage over the calcium salt that being soluble it may be administered in liquid form.

Dose, ordinarily five to fifteen grains (0.3–1 Gm.), although much larger quantities may be given safely.

Off. Prep.—Elixir Calcii et Sodii Glycerophosphatum, *N. F.*; Elixir Glycerophosphatum Compositum, *N. F.*; Elixir Terpini Hydratis et Creosoti Compositum, *N. F.*

SODII HYDROXIDUM. U. S.

SODIUM HYDROXIDE Sod. Hydrox. [Caustic Soda]

"Sodium Hydroxide contains not less than 90 per cent. of NaOH. *Caution—Great care is necessary in handling it, as it rapidly destroys organic tissue.*" *U. S.* "Sodium Hydroxide of commerce purified by means of alcohol." *Br.*, 1914 Appendix.

Soda Caustica; Sodium Hydrate; Hydrate of Soda; Natrium Causticum; Natrium Hydroxydatum; Soude caustique, *Fr.*; Natron, Aetznatron, *G.*; Soda caustica, *It.*; Hidrato sodico, *Sp.*

In the U. S. P. V and previous editions, this salt was prepared by acting upon a solution of sodium carbonate with a suspension of calcium hydroxide and after filtering off the precipitated calcium carbonate, evaporating the solution. At present there is no official recognized method.

Sodium hydroxide has been made on a large scale by simply modifying the Leblanc process (see *Sodii Carbonas*), so that more coal is added in the black-ash fusion, when carbonate is reduced to hydroxide with the liberation of carbon monoxide by the action of the quick-lime, the reactions being:

$$CaCO_3 + C = CaO + 2CO$$

$$Na_2CO_3 + CaO + H_2O = 2NaOH + CaCO_3$$

It is also made like the corresponding compound, caustic potash, by the decomposition of sodium carbonate in solution by quick-lime.

The manufacture of caustic soda by electrolytic means from brine in the United States has developed very greatly. In this sodium chloride is decomposed, the sodium uniting with the elements of water to form the hydroxide and the chlorine which is liberated, being absorbed by slaked lime furnishes the bleaching powder of commerce (see *Calx Chlorinata*).

There are three separate methods in use.

1. The electrolysis of solution of sodium chloride without diaphragms. 2. The electrolysis of sodium chloride with diaphragms. 3. The electrolysis of fused sodium chloride. The composition of the electrodes is of great importance. The materials used are retort graphite, platinum, and artificial graphite. The latter form is usually preferred. In the diaphragm

process, partitions of porous earthenware serve to keep the products of electrolytic decomposition separate to a certain extent, thus minimising the production of interfering compounds. The Acker process of electrolyzing fused sodium chloride is used at Niagara Falls.

Sodium hydroxide, or "caustic soda," of commerce, occurs in hard grayish-white rods or cakes, deliquescent, very alkaline and corrosive. It usually contains as impurities alumina, carbonates, chlorides, phosphates, and sulphates.

Purified Sodium Hydroxide may be obtained by dissolving caustic soda in ethylic alcohol, filtering the solution, evaporating it to dryness in a silver dish, occasionally adding distilled water during the evaporation. The residue is *Purified Sodium Hydroxide.* It should yield no characteristic reaction with the tests for phosphates or sulphates, and not more than the slightest reactions with the tests for carbonates. It is not quite free from alumina.

Description and Physical Properties.—"Dry, white, or nearly white, fused masses, or sticks, hard and brittle, showing a crystalline fracture. Exposed to the air, it deliquesces, absorbs carbon dioxide, and becomes covered with a coating of carbonate. One Gm. of Sodium Hydroxide is soluble in 0.9 cc. of water at 25° C. One Gm. is soluble in about 0.3 cc. of boiling water. It is very soluble in alcohol.

"A solution of Sodium Hydroxide even when greatly diluted is strongly alkaline to litmus paper. An aqueous solution of Sodium Hydroxide (1 in 25) responds to the reactions for sodium.

"An aqueous solution of Sodium Hydroxide (1 in 20) is clear and colorless (*organic matter or insoluble impurities*), and, after being acidulated with acetic acid, it yields no precipitate on the addition of an excess of tartaric acid T.S. or upon the addition of a few drops of sodium cobaltic nitrite T.S. (*potassium*). An aqueous solution of Sodium Hydroxide (1 in 50), slightly acidulated with hydrochloric acid, meets the requirements of the test for *heavy metals.*

"**Assay.**—Place about 10 Gm. of Sodium Hydroxide in a glass-stoppered weighing bottle, and weigh accurately. Transfer it to a 500 cc. graduated flask, dissolve it in 250 cc. of recently boiled distilled water, and add 30 cc. of barium chloride T.S. Fill the flask to the mark with recently boiled distilled water, and thoroughly agitate the liquid. Filter it through a filter, which has not been previously moistened, into a dry flask, rejecting the first 20 cc., and titrate 100 cc. of the subsequent clear filtrate with normal hydrochloric acid, using phenolphthalein T.S. as indicator. Each cc. of normal hydrochloric acid corresponds to 0.04001 Gm. of $NaOH$.

"Preserve in well-closed containers. If bottles are used as containers, they must be made of hard glass and cork stoppers, if used, should be paraffined." *U. S.*

When heated it melts, and at an intense heat evaporates. Though deliquescent, like potassium hydroxide, it does not, like that alkali, become permanently liquid, but forms a paste, which after a time effloresces. The difference in this respect between the two alkalies is owing to the circumstance that, while both are converted into carbonates by uniting with the carbon dioxide of the air, potassium hydroxide forms a deliquescent and sodium hydroxide an efflorescent salt. It is apt to contain 20 or 25 per cent. of water and impurities originating from the sodium carbonate used in preparing the solution from which it is made. The official volumetric assay permits the presence of 10 per cent. of water and impurities, but limits the fixed impurities to 2 per cent.

If the solution be colored brown by hydrogen or ammonium sulphide, the presence of lead may be suspected, derived probably from the glass vessels in which it has been kept.

Uses.—Sodium hydroxide is rarely employed as an internal remedy. Its most important medical use is as a caustic for the same class of cases in which potassium hydroxide is employed. (See under *Potassii Hydroxidum.*) It has the advantage over the latter of being less deliquescent and is probably milder. Its chief use is in various chemical and pharmaceutical manipulations.

Sodium hydroxide when taken in overdose acts as a caustic poison, although not quite so severe as the potassium hydroxide. Accidental poisoning is not uncommon, especially in children, because of its domestic use as lye. The symptoms are pain in the throat, vomiting—which may become bloody—abdominal cramps with purging, swelling and discoloration of the visible mucous membranes, and collapse. The most important factor in the treatment is the immediate neutralization of the poison. For this purpose vinegar or lemon juice (in tablespoonful doses, diluted) are efficient; olive oil, or other bland oil, is also of service. If the patient survive the immediate danger there is very likely to be such serious sequelæ from the destruction of the mucous membranes of the alimentary tract that death may follow later from starvation. For further details see under *Potassii Hydroxidum.*

Off. Prep.—Liquor Sodii Hydroxidi, *U. S.*

SODII HYPOPHOSPHIS. N. F., Br.

SODIUM HYPOPHOSPHITE Sod. Hypophos.

"Sodium Hypophosphite contains not less than 98 per cent. of $NaPH_2O_2.H_2O$ (106.07). Caution should be observed in dispensing Sodium Hypophosphite, as an explosion is liable to occur if it is triturated or heated with nitrates, chlorates or other oxidizing agents." *N. F.*

"Sodium Hypophosphite may be obtained by the interaction of sodium carbonate and calcium hypophosphite. When dried at 110° C. it contains not less than 97 per cent. of pure sodium hypophosphite, $NaPH_2O_2$." *Br.*

Natrium Hypophosphorosum, Hypophosphis Sodicus; Hypophosphite of Soda; Natrium Hypophosphorosum, *Fr. Cod.;* Hypophosphite de Sodium, *Fr.;* Unterphosphorigsaures Natron, *G.;* Hipofosfito sodico, *Sp.*

Preparation.—*Sodium hypophosphite* is prepared by mixing solutions of calcium hypophosphite and monohydrated sodium carbonate, in the proportion of eight ounces of the former, dissolved in five pints of water, to six of the latter in two pints of water. Double decomposition takes place, with the formation of calcium carbonate and sodium hypophosphite, of which the latter is held in solution and the former is precipitated.

$$Ca(H_2PO_2)_2 + Na_2CO_3 = 2NaH_2PO_2 + CaCO_3$$

After filtration to separate the calcium carbonate, the solution is evaporated to a pellicle, and then stirred constantly until the salt granulates, the heat being continued. If required quite pure, the granulated salt is dissolved in official alcohol, and the liquid, having been evaporated to a syrupy consistence, is set aside to crystallize.

Sometimes sodium hypophosphite explodes with violence during the evaporation of its solution. This was ascribed to the use of too high a temperature; but the same accident has occurred when the heat was applied by means of a water bath. In the *Chemical News* (No. 31, p. 46), Tuson stated that, though he had superintended the manufacture of large quantities of calcium and sodium hypophosphites, he had never witnessed anything like an explosion; but the heat employed in evaporation had never approached 100° C., and this is probably the true explanation. Caution, therefore, should be observed to evaporate at a low temperature.

Description and Physical Properties.—"Sodium Hypophosphite occurs as small, colorless, transparent, rectangular plates of a pearly luster, or as a white, granular powder; odorless, and having a saline taste. It is deliquescent on exposure to moist air. One Gm. of Sodium Hypophosphite dissolves in 1 cc. of water at 25° C.; also in about 0.15 cc. of boiling water; soluble in alcohol, slightly soluble in dehydrated alcohol, and freely soluble in glycerin at 25° C.; freely soluble in boiling alcohol.

"An aqueous solution of Sodium Hypophosphite (1 in 20) is neutral or slightly alkaline to litmus. When heated in a test tube, the salt at first loses its water of crystallization, and upon further heating is decomposed, evolving spontaneously inflammable hydrogen phosphide, which burns with a bright yellow flame. To a non-luminous flame the salt imparts an intensely yellow color. When an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added drop by drop with agitation to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. Upon the further addition of the solution of Sodium Hypophosphite, the precipitate becomes gray from reduction to metallic mercury.

"A solution of 1 Gm. of the salt in about 10 cc. of distilled water requires not more than 1.5 cc. of tenth-normal hydrochloric acid for neutralization, methyl orange T.S. being used as indicator. Heat 5 cc. of an aqueous solution of the salt (1 in 5) in a test tube with 0.5 cc. of diluted hydrochloric acid on a water bath for thirty minutes; no offensive odor is developed. Measure 5 cc. of an aqueous solution of the salt (1 in 25) into a beaker containing 3 cc. of nitric acid, diluted with about 10 cc. of distilled water, and evaporate the mixture to dryness on a water-bath; the residue meets the requirements of the Test for arsenic. An aqueous solution of the salt does not respond to the Test for heavy metals. Add magnesia mixture T.S. to 10 cc. of an aqueous solution of the salt (1 in 20), made alkaline with ammonia water; it is not affected within one minute (*phosphate*).

"**Assay.**—Dissolve about 1 Gm. of Sodium Hypophosphite, previously dried for twenty-four hours over sulphuric acid and accurately weighed, in 10 cc. of distilled water, add 10 cc. of nitric acid and evaporate the solution to dryness on a water bath. Dissolve the residue in 20 cc. of distilled water, add a drop of phenolphthalein T.S. and sufficient special potassium hydroxide T.S. (see Reagents U. S. P.) to produce a pink color, and then dilute to exactly 100 cc. with distilled water. Transfer 10 cc. of this solution to a 100 cc. graduated flask, add 50 cc. of tenth-normal silver nitrate and proceed from this point as directed in the assay under Potassii Hypophosphis. Each cc. of tenth-normal silver nitrate used corresponds to 0.0035357 Gm. of $NaPH_2O_2.H_2O$. Each Gm. of Sodium Hypophosphite corresponds to not less than 277.2 cc. of tenth-normal silver nitrate.

"Preserve in well-closed containers." *N. F.*

"White granules, deliquescent. Taste bitter, nauseous. Soluble in 1 part of *water* and in 30 parts of *alcohol* (90 per cent.); insoluble in *ether.* Yields, when heated, spontaneously inflammable hydrogen phosphide and hydrogen. Yields the *reactions characteristic* of sodium. Rapidly attacked by oxidising agents. Its solution yields with a warm aqueous solution of *copper sulphate* a red precipitate of cuprous hydride, which on boiling evolves hydrogen. Yields no characteristic *reactions* for copper, iron, aluminium, zinc, calcium, magnesium, potassium, or ammonium, and not more than the slightest *reactions* for carbonates, chlorides, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million. Loses not more than 2 per cent. of its weight when dried at 110° C. When the salt thus dried is assayed by the process described under 'Calcii Hypophosphis' not more than 28 millilitres of *N/10 solution of sodium thiosulphate* are required to decolorise the iodine liberated, corresponding to not less than 97 per cent. of pure sodium hypophosphite, $NaPH_2O_2$." *Br.*

The solubility of sodium hypophosphite is increased by the addition of hypophosphorus acid. As the soluble salts of mercury and silver are reduced by the hypophosphites, they are, of course, incompatible with sodium hypophosphite in prescriptions.

Uses.—This preparation is as useless as the other hypophosphites (See *Acidum Hypophosphorosum*).

Dose, ten to twenty grains (0.65–1.3 Gm.), three times a day.

Off. Prep.—Emulsum Olei Morrhuæ cum Hypophosphitibus, *N. F.;* Liquor hypophosphitum Compositus, *N. F.;* Syrupus Calcii et Sodii Hypophosphitum, *N. F.;* Syrupus Hypophosphitum Compositus, *N. F.*

SODII INDIGOTINDISULPHONAS. U. S.

SODIUM INDIGOTINDISULPHONATE Sod. Indigotin. [Indigo Carmine]

"Chiefly the sodium salt [$C_{16}H_8O_2N_2(SO_3Na)_2$] of indigotindisulphonic acid." *U. S.*

Sodium Indigodisulphonate; Soluble Indigo; Sodium Coerulein-sulphonate; Coeruline; Ceruleinum; Indigo Soluble, *Fr. Cod.*

Indigotin, commonly called *indigo blue,* $C_{16}H_{10}O_2N_2$, is a neutral, tasteless, dark blue powder, insoluble in water. When this is acted upon by sulphuric acid it forms disulphindigotic (sulpho-coerulic) acid, $C_{16}H_8N_2O_2(HSO_3)_2$. This acid is neutralized by sodium and the official salt is produced.

Description and Physical Properties.—"A blue powder or a dark purple paste. When compressed, it acquires a coppery luster. Sodium Indigotindisulphonate is sparingly soluble in water, yielding a dark blue solution. It is almost insoluble in alcohol.

"If in the form of paste, Sodium Indigotindisulphonate should be deprived of water by drying to constant weight at 100° C. before applying the following tests: The addition of nitric acid, bromine T.S., or chlorine T.S. to an aqueous solution of the salt (1 in 200) discharges the blue color. The blue color is also discharged by warming the solution with sodium hydroxide and zinc dust or with stannous chloride T.S.

"Dissolve 1 Gm. of Sodium Indigotindisulphonate, previously dried to constant weight at 100° C., in 200 cc. of distilled water, filter the solution through counterbalanced filters or a Gooch crucible, wash the residue and the filters with distilled water until the washings cease to be colored blue, and dry at 100° C.: the residue remaining on the filter does not exceed 2 per cent. Boil 0.2 Gm. of Sodium Indigotindisulphonate for two minutes with 10 cc. of distilled water, cool, and then agitate the solution with small portions of bromine T.S. until the blue color disappears. On now adding a few drops of potassium iodide T.S. to the liquid, no blue color is produced (*starch or starch iodide*). Add 15 cc. of hydrogen dioxide T.S. and 10 cc. of sodium hydroxide T.S. to 0.2 Gm. of the salt, shake the mixture until the blue color disappears, evaporate the liquid to about 10 cc., cool, acidulate with hydrochloric acid, and add a few drops of ferrous sulphate T.S.: no blue color is produced (*iron ferricyanide or ferrocyanide*)." *U. S.*

Uses.—This salt is used as a dye and also as a microscopic stain and in certain chemical reagents both for qualitative and quantitative tests. It is official for the purpose of coloring the tablets of corrosive sublimate (see *Toxitabellæ Hydrargyri Chloridi Corrosivi,* U. S.).

Indigo carmine has also been used as a test of kidney function. For this purpose 0.08 Gm. (one and one-third grains) is injected intramuscularly and the urine collected at the end of ten minutes and each hour thereafter for three hours. The proportion of dye eliminated is determined by comparing the depth of color in the urine with a standard solution. Normally the dye should appear within less than ten minutes and about 10 per cent. should be eliminated within the first hour. For further information on this test, see Thomas and Birdsall (*J. A. M. A.,* 1917, lxix, 1747).

SODII IODIDUM. U. S., Br.

SODIUM IODIDE Sod. Iod.

"Sodium Iodide, when dried to constant weight at 120° C., contains not less than 99 per cent. of NaI. It contains not more than 7 per cent. of water." *U. S.* "Sodium Iodide may be obtained from iodine and sodium hydroxide by a process similar to that employed in making Potassium Iodide, the salt being crystallised at a temperature not lower than 20° C. When dried at 110° C. it contains not less than 99 per cent. of pure sodium iodide, NaI." *Br.*

Iodurum Sodicum; Natrium Iodatum, *Fr. Cod.;* Iodure de Sodium, *Fr.;* Natrium Jodatum, *P. G.;* Natriumjodid, Jodnatrium, *G.;* Yoduro sodico, *Sp.*

This iodide may be prepared either by treating a solution of sodium hydroxide with iodine, or by double decomposition between ferrous iodide and sodium carbonate, precisely as potassium iodide is obtained by the corresponding processes for that salt.

It crystallizes in anhydrous cubes from a hot solution, and in oblique rhombic prisms, with two molecules of water, by spontaneous evaporation.

Description and Physical Properties.—"Colorless, odorless, cubical crystals, or a white, crystalline powder. In moist air Sodium Iodide deliquesces, or at first cakes and then deliquesces, and frequently undergoes decomposition, assuming a brown tint. One Gm. of Sodium Iodide is soluble in 0.55 cc. of water, in about 2 cc. of alcohol, and in 1 cc. of glycerin, at 25° C. One Gm. is soluble in 0.4 cc. of boiling water. When heated to about 660° C., Sodium Iodide melts, and at higher temperatures it is slowly volatilized and partly decomposed.

"An aqueous solution of the salt (1 in 20) responds to the reactions for sodium, and for iodides.

"Dissolve 1 Gm of Sodium Iodide in 10 cc. of distilled water, and add 0.15 cc. of tenth-normal sulphuric acid: no red color is produced by the addition of a drop of phenolphthalein T.S. (*alkali*). A solution of 1 Gm. of the salt in 2 cc. of distilled water yields no precipitate with 1 cc. of sodium bitartrate T.S. (*potassium*). Dissolve 0.5 Gm. of the salt in 10 cc. of distilled water which has been previously boiled and cooled, and add 2 drops of diluted sulphuric acid: no distinct, yellow color appears within half a minute (*iodate*), and no turbidity occurs (*thiosulphate*). Add 5 cc. of sodium hydroxide T.S. and about 0.2 Gm. of aluminum wire to a solution of 1 Gm. of Sodium Iodide in 5 cc. of distilled water contained in a test tube of about 40 cc. capacity. Insert a pledget of purified cotton in the upper portion of the test tube, and place a piece of moistened red litmus paper over its mouth. On heating the tube and contents on a water bath for fifteen minutes, no blue coloration of the paper is discernible (*nitrate or nitrite*). A 10 cc. portion of an aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is not rendered turbid by the addition of 1 cc. of potassium sulphate T.S. (*barium*). A 2 Gm. portion of Sodium Iodide shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid. Heat gently 5 cc. of an aqueous solution of the salt (1 in 10) with 1 drop of ferrous sulphate T.S., 1 drop of ferric chloride T.S., and 0.5 cc. of sodium hydroxide T.S.: no blue color appears after acidulating the mixture with hydrochloric acid (*cyanide*). An aqueous solution of the salt meets the requirements of the test for *heavy metals*. Dry the salt to constant weight at 120° C.: the loss in weight does not exceed 7 per cent. (*water*).

"**Assay.**—Proceed as directed under the assay for iodides, using about 0.5 Gm. of Sodium Iodide, previously dried to constant weight at 120° C. and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.01499 Gm. of NaI. Each Gm. of Sodium Iodide, previously dried, corresponds to not less than 66 cc. and not more than 67.7 cc. of tenth-normal silver nitrate.

"Preserve in well-closed containers." *U. S.*

"A white crystalline powder, deliquescent. Taste saline and somewhat bitter. Soluble in less than 1 part of *water* and in 3 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of sodium and of iodides. Loses not more than 5 per cent. of its weight when dried at 110° C.; 0.5 gramme of this dried salt requires for complete precipitation not less than 33.0 or more than 33.9 millilitres of *N/10 solution of silver nitrate*. Yields no characteristic *reactions* for copper, iron, aluminium, calcium, magnesium, potassium, ammonium, bromates, cyanides, carbonates, or iodates, and not more than the slightest *reactions* for bromides, chlorides, or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Sodium iodide possesses the same incompatibilities as the other soluble iodides. It produces insoluble precipitates with mercurous, lead and silver salts and even weak oxidizing agents liberate iodine from it when the solution.

Uses.—Sodium iodide has the same therapeutic effects as the other iodides. (See *Iodum.*) It is said to be better borne by the stomach than potassium iodide, although it contains 8 per cent. more iodine. Pfannenstill (*D. M. W.*, 1911, p. 2420) asserts that by the conjoint internal administration of large doses of sodium iodide and hydrogen peroxide externally, a local liberation of free iodine may be obtained at the point of application of hydrogen dioxide. He recommends this method of treatment, especially in *tuberculous ulcers* of the mucous membrane and in *lupus*. His method has received some confirmation, and Reuterskiold (*Cb. Chir.*, 1911, p. 985) has found it of service in various surgical conditions, such as *osteomyelitis, cellulitis, infected leg ulcers*, etc. Cameron and Grundy (*J. A. M. A.*, 1918, lxxi, 1516) recommend the use of a 25 per cent. solution for roentgenography of the urinary tract, the salt being opaque to the X-ray.

Dose, five to thirty grains (0.32–2.0 Gm.).

Off. Prep.—Syrupus Ferri et Mangani Iodidi, *N. F.*; Elixir Euphorbiæ Compositum, *N. F.*

SODII NITRIS. U. S., Br.

SODIUM NITRITE Sod. Nitris.

"Sodium Nitrite, when dried to constant weight over sulphuric acid, contains not less than 95 per cent. of $NaNO_2$." *U. S.* "Sodium Nitrite may be obtained by fusing sodium nitrate with metallic lead. It contains not less than 95 per cent. of pure sodium nitrite, $NaNO_2$." *Br.*

Nitrite of Sodium; Nitrite de Soude, *Fr.*; Natrium Nitrosum, *P. G.*; Salpetrigsaures Natron, *G.*

Preparation.—According to M. A. Darbon, it is made on a large scale as follows: Sodium nitrate is melted in large cast iron vessels, whereby hygroscopic water is removed and a part of the iodides and iodates, still present, are decomposed. At 310° C. the nitrate begins to fuse. It is heated to 400° to 420° C., and pure metallic lead in thin sheets is gradually added, the mass being constantly stirred, about 280 parts of lead being necessary for 100 parts of sodium nitrate used. The lead must be as free as possible from other metals and antimony particularly must be absent. When all the lead has been added, care having been exercised to prevent overheating, the stirring must be kept up for some time, and the melted mass is then, by means of a cast iron ladle, run in the form of thin threads into water with constant stirring.

In this process, besides the nitrite, about 1 per cent. of sodium hydroxide is produced, which in its turn dissolves a portion of lead, and has to be removed during the subsequent purification, either by nitric acid or by lead nitrate or sulphuric acid. The crude products are a solution containing the nitrite, undecomposed saltpeter, sodium hydroxide holding lead in solution, the soluble impurities of the sodium nitrate, such as sodium chloride, etc., and a residue consisting of lead oxide, a little metallic lead, and a certain proportion of lead peroxide. The solution strained from the residue, with the washings, is diluted to about 6° to 8° B., neutralized with nitric acid as long as a precipitate is formed, separated from this precipitate, concentrated to 42° to 45° B. while warm, and then left to crystallize—the crystals requiring possibly recrystallization. The pure crystals are separated by a centrifugal machine, washed, dried and packed in cylinders of double thickness of parchment paper. (*Chem. News,* Sept. 22, 1899, 146.)

Another process is by heating sodium nitrate with quick-lime and passing in a current of SO_2.

$$NaNO_3 + CaO + SO_2 = NaNO_2 + CaSO_4$$

Still another source of sodium nitrite is as a by-product from the synthetic process of making nitric acid from atmospheric nitrogen by the use of the electric current. Most of the European nitrite now comes from Norway as a result of this process.

Description and Physical Properties.—"White, or nearly white, opaque, fused masses or sticks; or colorless, transparent crystals; or a white or slightly yellow granular powder. It is odorless and has a mild saline taste. When exposed to the air, Sodium Nitrite deliquesces and is gradually oxidized to sodium nitrate, making it unfit for use. One Gm. of Sodium Nitrite is soluble in 1.5 cc. of water at 25° C. It is sparingly soluble in alcohol, and is very soluble in boiling water. When heated to about 270° C. the salt melts, and at a red heat it decomposes yielding oxygen, nitrogen, nitrous oxides, and sodium oxide.

"An aqueous solution of the salt responds to the reactions for sodium, and for nitrites. An aqueous solution of the salt (1 in 20) is slightly alkaline to litmus paper.

"Dissolve 0.5 Gm. of Sodium Nitrite in 25 cc. of diluted hydrochloric acid, evaporate the solution to dryness, and dissolve the residue in 25 cc. of distilled water, adding a few drops of diluted hydrochloric acid: a 10 cc. portion of the resulting solution meets the requirements of the test for *heavy metals.*

"**Assay.**—Dry about 1 Gm. of Sodium Nitrite to constant weight over sulphuric acid, weigh accurately in a stoppered weighing-bottle, dissolve the salt in a measuring flask with sufficient distilled water to make 100 cc., and add 10 cc. of this solution, from a pipette, to a mixture of 50 cc. of tenth-normal potassium permanganate, 100 cc. of distilled water, and 5 cc. of sulphuric acid. In adding the sodium nitrite solution, immerse the tip of the pipette beneath the surface of the permanganate mixture. Warm the liquid to 40° C., allow it to stand for five minutes, and then titrate with tenth-normal oxalic acid. Each cc. of tenth-normal potassium permanganate corresponds to 0.003451 Gm. of $NaNO_2$.

"Preserve in well-closed containers." *U. S.*

Another method of assay has been proposed by Kalmann which is based upon the following reaction:

$$NaNO_2 + 2HI = NaI + I + NO + H_2O$$

When carried out under specified conditions it is stated to be very satisfactory. (*J. P. C.,* 1918, xviii, 217.)

"A white crystalline powder, deliquescent. Taste saline. Soluble in 1.5 parts of *water.* Yields the *reactions* characteristic of sodium and nitrites. 0.1 gramme dissolved in *water* decolorises not less than 27.5 millilitres of *N/10 solution of potassium permanganate,* the solution being maintained slightly acid. Aqueous solution neutral or only slightly alkaline to *litmus;* gives no precipitate on the addition of *diluted sulphuric acid* (absence of lead). *Arsenic limit* 5 parts per million." *Br.*

Uses.—The injection of a nitrite into the circulation produces an increase in the rate of the pulse with a marked fall of blood pressure. At the same time if the dose has been sufficient there develops motor weakness and diminution of reflex activity. After toxic doses the breathing becomes rapid and often of dyspneic character, the mucous membranes of a peculiar slate color, and convulsions may occur. The acceleration of the heart rate is due to a depressant action upon the cardio-inhibitory center in the medulla. The fall of blood pressure is due to a dilatation of the arteries through a direct action upon the muscular coat of their walls. (See Pilcher and Sollmann, *J. P. Ex. T.,* 1915, vi, 323.) The vessels of the lungs do not share in this action, for H. C. Wood, Jr. (*J. Ex. M.,* 1911, xiv), has shown that the pulmonary artery is contracted rather than dilated. Lieb and McWhorter (*J. P. Ex. T.,* 1915, vii, 93) have found that the nitrites relax the tonus of the gall-bladder muscles; and it is to be presumed that they have the same effect on all unstriped muscle. As was first shown by H. C. Wood (*Am. J. M. S.,* July, 1871), the motor weakness and diminished reflexes are the result of an action upon the spinal cord. The increased breathing is not due to any action upon the respiratory center, but is a response to the deprivation of the system for oxygen which is brought about through chemical alteration of the coloring matter of the blood. Whether or not the new compound formed is identical with methemoglobin, which results from the action of a number of poisons, is at present uncertain, but it is a so much more stable compound than oxyhemoglobin that the system is unable to obtain sufficient oxygen to maintain normal functions.

Of the various compounds which liberate the nitrite ion in the system and produce the physiological results described above, those official are amyl nitrite, glyceryl nitrate, ethyl nitrite, and sodium nitrite. The difference between the effects of these drugs is chiefly in their rapidity and duration. The influence of amyl nitrite may be perceived usually within 30 seconds after its administration, and lasts for from 5 to 10 minutes, that of nitroglycerin begins within 1 or 2 minutes, and rarely endures more than one-half hour, sodium nitrite manifests its action in from 5 to 10 minutes and lasts for about 2 hours. (See Wallace and Ringer, *J. A. M. A.*, 1909, liii, 1629.)

The most important use of sodium nitrite is for the purpose of reducing arterial pressure in threatened *apoplexy,* certain types of *chronic nephritis,* the early stages of *arterial degenerations,* and other conditions of too *high blood-pressure.* In arterio-sclerosis, after actual degenerative changes have taken place in the walls of the blood vessels, although widely employed it is incapable of much benefit because when the muscular tissue is replaced by connective tissue the drug can no longer cause dilatation of the arteries. On the other hand, in those forms of too high blood pressure in which there is no degenerative change in the walls of the vessels it is one of the most valuable drugs we possess to cause a temporary reduction. It has the great advantage over nitroglycerin in the longer duration of its effects. In convulsive disorders the nitrites are useful only for immediate effects and for this purpose the other preparations are superior to the sodium salt.

Because of its deliquescence sodium nitrite should be prescribed only in solution and should always be given well diluted, but even with the greatest care it will very often cause such marked gastric disturbance as to interdict its use.

Dose, one to three grains (0.065–0.2 Gm.).

Off. Prep.—Spiritus Ætheris Nitrosi, *U. S.*

SODII PERBORAS. N. F.

SODIUM PERBORATE Sod. Perbor.

" Sodium Perborate contains not less than 9 per cent. of available oxygen, corresponding to about 86.5 per cent. of $NaBO_3.4H_2O$ (154.06)." *N. F.*

Sodium perborate is made by decomposing sodium peroxide with acid under a patented process.

In the presence of water, this salt undergoes decomposition with the formation of hydrogen dioxide and sodium metaborate, the resulting solution being slightly alkaline in reaction.

$$NaBO_3 + H_2O = H_2O_2 + NaBO_2$$

In the dried state, sodium perborate, if pure, is permanent in the air. Commercial varieties of sodium perborate yield from 5 per cent. to 10 per cent. of free oxygen.

Description and Physical Properties.—" Sodium Perborate occurs as white, crystalline granules or as a powder; odorless, and having a saline taste. It is stable in cool and dry air, but is decomposed with the evolution of oxygen in warm or moist air. Sodium Perborate is soluble in water.

"A saturated aqueous solution of the salt is alkaline to litmus or phenolphthalein T.S. In aqueous solution the salt is decomposed into sodium metaborate and hydrogen dioxide, the solution gradually evolving oxygen. Oxygen is evolved more rapidly if the solution is warmed. The salt imparts an intensely yellow color to a non-luminous flame. Turmeric paper, if moistened with an aqueous solution of the salt which has been acidulated with hydrochloric acid, becomes brown in color, particularly on drying; on moistening the dried test paper with ammonia water, the color is changed to greenish black. Agitate a mixture of 1 cc. of an aqueous solution of the salt (1 in 50), 1 cc. of diluted sulphuric acid, a few drops of potassium dichromate T.S., and 2 cc. of ether; the ether acquires a blue color.

" Strongly heat 0.5 Gm. of the salt in a platinum crucible, and dissolve the residue in 25 cc. of distilled water with the aid of a few drops of hydrochloric acid; 10 cc. of the resulting solution does not respond to the Test for heavy metals.

"**Assay.**—Dissolve about 0.25 Gm. of the salt, accurately weighed, in a mixture of 50 cc. of distilled water and 10 cc. of diluted sulphuric acid and titrate the solution with tenth-normal potassium permanganate. Each cc. of tenth-normal potassium permanganate corresponds to 0.0008 Gm. of available oxygen. Each Gm. of Sodium Perborate corresponds to not less than 112.5 cc. of tenth-normal potassium permanganate.

" Preserve it in well-closed containers, in a cool place." *N. F.*

Under the trade name of *Pergenol* has also been introduced a mixture of sodium perborate and sodium bitartrate. This is asserted to correspond to 12 per cent. of hydrogen dioxide, so that the preparation of a solution corresponding to the official solution of hydrogen dioxide requires one part of pergonal and three of water. *Perboral* is a mixture of the perboric acid and para-iodo-sulfonic acid. According to Jaubert (*B. M. J.*, 1905), *perborax* has the formula $Na_2B_4O_8 + 10H_2O$.

Uses.—Sodium perborate is used as a means of obtaining the therapeutic effects of hydrogen dioxide. According to Herbol (*D. M. W.*, 1908, p. 1092), a 2 per cent. solution of sodium perborate is equivalent in germicidal activity to an 0.4 per cent. solution of hydrogen dioxide. In *wounds* or *ulcers* it may be used in solution or as a dusting powder. For the preparation of antiseptic mouth wash it has the advantage over the solution of the dioxide of hydrogen of being alkaline instead of acid. It has also been employed in various skin diseases, especially in acne vulgaris. Herzfeld (*J. A. M. A.*, 1911, lvii, p. 6113) has used it not only as an antiseptic dressing in infected wounds, chronic ulcers, or diabetic gangrene, but as a hemostatic in epistaxis and other local bleedings. It may be employed either as a dusting powder or as a solution in strengths of from 2 per cent. upwards. It is rarely used internally.

Dose, one to three grains (0.065–0.2 Gm.).

Off. Prep.—Dentifricium, *N. F.*

SODII PHOSPHAS. U. S., Br.

SODIUM PHOSPHATE Sod. Phos.

"Sodium Phosphate contains not less than 39.25 per cent. and not more than 44.00 per cent. of Na_2HPO_4, corresponding to not less than 99 per cent. of the crystallized salt [$Na_2HPO_4.12H_2O$]." *U. S.* "Sodium Phosphate may be obtained by the interaction of sodium carbonate and the solution of acid calcium phosphate produced on mixing bone-ash and sulphuric acid. It contains not less than 99.5 per cent. of pure di-sodium hydrogen phosphate, $Na_2HPO_4,12H_2O$." *Br.*

Tribasic Sodium Phosphate; Sodium Orthophosphate; Phosphate of Soda; Disodium Hydrogen Phosphate; Phosphas Sodicus (Natricus); Phosphas Bisodicus; Sal Mirabile Perlatum; Phosphate Monoacide de Sodium, Phosphate Disodique, *Fr.;* Natrium Phosphoricum, *P. G.;* Natriumphosphat, Phosphorsaures Natron, *G.;* Fosfato bisodico, *It.;* Fosfato sodico, *Sp.*

A process for this salt is no longer official; for that of the U. S. P., 1870, see *U. S. Disp.*, 19th edition, page 1151.

The incombustible part of bones is obtained by burning them to whiteness, and consists of neutral calcium phosphate, called bone phosphate, associated with some calcium carbonate, etc. When this is mixed with sulphuric acid, the calcium carbonate is entirely decomposed, giving rise to effervescence. The calcium phosphate undergoes partial decomposition; the greater part of the lime, being detached, precipitates as calcium sulphate, while the phosphoric acid, set free, combines with the undecomposed portion of the phosphate, and remains in solution as an acid calcium phosphate, holding dissolved a small portion of the calcium sulphate. In order to separate the acid phosphate from the precipitated mass of calcium sulphate, boiling water is added to the mixture, the whole is strained, and the sulphate washed as long as acid phosphate is removed, which is known by the water passing through in an acid state. The different liquids which have passed the strainer, consisting of the solution of acid calcium phosphate, are mixed and allowed to stand, and by cooling a portion of calcium sulphate is deposited, which is removed by decantation. The bulk of the liquid is now reduced by evaporation, and, in consequence of the diminution of the water, a fresh portion of calcium sulphate is deposited, which is separated by subsidence and decantation as before. The acid calcium phosphate solution, being heated, is now saturated by means of a hot solution of sodium carbonate. The calcium carbonate is separated by a new filtration, and the filtered liquor, which is a solution of sodium phosphate, is evaporated so as to crystallize.

The reactions are as follows:

$$Ca_3(PO_4)_2 + 2H_2SO_4 = 2CaSO_4 + Ca(H_2PO_4)_2$$

$$Ca(H_2PO_4)_2 + 2Na_2CO_3 = 2Na_2HPO_4 + CaCO_3 + CO_2 + H_2O$$

Funcke, a German chemist, has given the following cheap and expeditious method for obtaining sodium phosphate. To the powdered calcined bone, diffused in water, sufficient diluted sulphuric acid is added to decompose all the calcium carbonate which it contains. When the effervescence ceases, the matter is treated with nitric acid, which dissolves the calcium phosphate and leaves the sulphate. The nitric solution of the phosphate is then treated with sodium sulphate, equal in quantity to the bone employed, and after the reaction is completed, the nitric acid is recovered by distillation. In consequence of a double decomposition, calcium sulphate and sodium phosphate are formed, the latter of which is separated by water, and crystallized in the usual manner.

Description and Physical Properties.—"Large, colorless, odorless, monoclinic prisms, or a granular, crystalline salt. The crystals effloresce in the air. One Gm. of Sodium Phosphate is soluble in 2.7 cc. of water at 25° C. It is very slightly soluble in alcohol. When heated to about 40° C., the salt fuses, yielding a colorless liquid. At 100° C. it loses all of its water of crystallization, and at about 300° C. is converted into sodium pyrophosphate.

"An aqueous solution of Sodium Phosphate (1 in 10) is alkaline to litmus paper and phenolphthalein T.S. An aqueous solution of the salt (1 in 20) responds to the reactions for sodium, and for phosphates.

"Dissolve 10 Gm. of Sodium Phosphate in 100 cc. of distilled water: not more than 0.02 Gm. of residue remains (*calcium or aluminum*). No effervescence occurs on the addition of hydrochloric acid to a solution of the salt (*carbonate*). One Gm. of Sodium Phosphate shows no more *chloride* than corresponds to 0.2 cc. of fiftieth-normal hydrochloric acid, and 0.2 Gm. shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid. An aqueous solution of the salt meets the requirements of the test for *heavy metals*. An aqueous solution of the salt meets the requirements of the test for *arsenic*.

"**Assay.**—Place about 0.4 Gm. of Sodium Phosphate, accurately weighed, in a 100 cc. graduated flask, dissolve it in 10 cc. of distilled water, add 50 cc. of tenth-normal silver nitrate, and thoroughly agitate the mixture. Gradually add reagent zinc oxide in small portions until the liquid is neutral to litmus paper. Then add distilled water to make 100 cc., agitate the mixture thoroughly, and filter through a filter which has not been previously moistened, rejecting the first 20 cc. of filtrate. Collect 50 cc. of the subsequent clear filtrate, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate to the production of a permanent red color. Each cc. of tenth-normal silver nitrate corresponds to 0.004735 Gm. of Na_2HPO_4.

"Preserve in well-closed containers." *U. S.*

"Transparent, colorless, rhombic prisms, efflorescent. Taste saline. Soluble in 7 parts of *water,* the solution being slightly alkaline to *litmus.* Yields the *reactions* characteristic of sodium and of phosphates. 5 grammes dissolved in 50 millilitres of *water* require for neutralisation not less than 13.9 millilitres of *N/1 solution of sulphuric acid, solution of methyl orange* being used as indicator. Yields no characteristic *reactions* for potassium, ammonium, carbonates, or chlorides, and not more than the slightest *reaction* for sulphates. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million." *Br.*

Samples of sodium phosphate have been found in commerce contaminated with arsenic in dangerous quantities. The official test to detect arsenic should always be applied to sodium phosphate. (*C. D.,* June 30, 1900, 1073; *Am. Drug.,* Aug. 27, 1900, 103.)

The medicinal sodium phosphate is one of the three sodium salts of tribasic phosphoric acid, H_3PO_4. In this salt two of the three replaceable hydrogen atoms have been replaced by sodium, so that its formula is HNa_2PO_4, which then crystallizes out with 12 molecules of water. Its complete formula is then $HNa_2PO_4 + 12H_2O$. When gently heated, it loses its water of crystallization (see *Sodii Phosphas Exsiccatus*) and at a red heat the salt is converted into *sodium pyrophosphate,* $Na_4P_2O_7$. (See *Sodii Pyrophosphas.*)

Sodium phosphate precipitates some of the alkaloidal salts, notably those of strychnine. It is also incompatible with the salts of calcium, magnesium and most of the heavy metals.

Uses.—Sodium phosphate was introduced into practice about the year 1800 by Pearson of London. In doses of from one to two ounces (31 to 62 Gm.) it is a mild purgative, and, from its pure saline taste, is well adapted to the cases of children, and of persons of delicate stomach. In smaller doses it has been considerably used, generally in connection with other phosphates, to meet any real or supposed deficiency of phosphates in the system, and for this purpose it is well adapted by its ready solubility. It is widely believed that it exerts, especially in children, an extraordinary influence upon the hepatic secretion. It is therefore employed in *constipation* where the stools are light in color, in infantile *diarrhea,* with *white* or *green stools,* and sometimes with *jaundice,* these evidences of deficient or disordered bile are said to quickly yield to small doses of sodium phosphate, the passages assuming their healthy yellow color, and the attendant disease generally disappearing. It probably, however, possesses only the virtues of the other saline laxatives.

Dose, as a laxative, from one to four drachms (3.9–15.5 Gm.); as a hepatic stimulant, from twenty to forty grains (1.3–2.6 Gm.) may be given, dissolved in water, after meals.

SODII PHOSPHAS EFFERVESCENS. U. S., Br.

EFFERVESCENT SODIUM PHOSPHATE

Sod. Phos. Eff.

Sodæ Phosphas Effervescens; Effervescent Phosphate of Soda; Natrium Phosphoricum Effervescens; Phosphate de Soude effervescent, *Fr.;* Brausendes Natriumphosphat, *G.*

"Exsiccated Sodium Phosphate, in fine powder, 200 Gm.; Sodium Bicarbonate, dried and powdered, 477 Gm.; Tartaric Acid, dried and powdered, 252 Gm.; Citric Acid, uneffloresced crystals, 162 Gm.; to make about 1000 Gm. Powder the citric acid, and mix it intimately with the exsiccated sodium phosphate and tartaric acid, and then thoroughly incorporate the sodium bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish in an oven heated to between 93° and 104° C. Manipulate the mixture carefully with a wooden spatula, and, when it has become moist, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. Immediately transfer the salt to suitable containers and seal them tightly. Care must be taken to prevent the product from coming in contact with air which contains moisture." *U. S.*

"Sodium Phosphate, in crystals, 500 *grammes;* Sodium Bicarbonate, in powder, 500 *grammes;* Tartaric Acid, in powder, 270 *grammes;* Citric Acid, in powder, 180 *grammes.* Dry the Sodium Phosphate until it has lost about 60 per cent. of its weight; powder the dried salt and mix it with the other ingredients. Place the whole in a dish or pan of suitable form heated to between 90° and 105° C. When the mixture, by aid of careful manipulation, has assumed a granular character, separate into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 55° C. The product weighs about one thousand grammes." *Br.*

This salt affords a pleasant means of giving sodium phosphate.

Dose, one-fourth to one-half ounce (7.7–15.5 Gm.).

SODII PHOSPHAS EXSICCATUS. U. S.

EXSICCATED SODIUM PHOSPHATE

Sod. Phos. Exsic.

"Exsiccated Sodium Phosphate, when dried to constant weight at 110° C., contains not less than 98 per cent. of Na_2HPO_4." *U. S.*

"*Sodium Phosphate,* a convenient quantity. Allow the crystals to effloresce for several days in warm air at a temperature of from 25° to 30° C., then continue the drying in an oven, raising the temperature very gradually until 110° C. has been reached. Maintain this temperature until the salt ceases to lose weight, powder and sift the residue, and transfer to well-closed containers." *U. S.*

Description and Physical Properties.—"A white powder which readily absorbs moisture. One Gm. of Exsiccated Sodium Phosphate is soluble in 8.1 cc. of water at 25° C. and in 1.1 cc. of boiling water. It is insoluble in alcohol.

"Exsiccated Sodium Phosphate meets the requirements of the tests for identity, and, after allowance is made for the loss of water of crystallization, meets the requirements of the tests for purity under *Sodii Phosphas.*

"**Assay.**—Proceed as directed under *Sodii Phosphas* using about 0.15 Gm. of the salt, previously dried to constant weight at 110° C. and accurately weighed. Each cc. of tenth-normal silver nitrate corresponds to 0.004735 Gm. of Na_2HPO_4.

"Preserve in well-closed containers." *U. S.*

Uses.—This salt was introduced in this form for use in making effervescent sodium phosphate. Forty parts of exsiccated sodium phosphate represent about 100 parts of crystallized sodium phosphate (see *Sodii Phosphas*), although in damp atmosphere it absorbs water readily and may contain from 10 to 25 per cent. The water content should always be determined before it is used in any important preparation. It is not used medicinally unless in combination.

Off. Prep.—Sodii Phosphas Effervescens, *U. S.*

SODII SALICYLAS. U. S., Br.

SODIUM SALICYLATE Sod. Salicyl.

"Sodium Salicylate, when dried to constant weight at 100° C., contains not less than 99.5 per cent. of $NaC_7H_5O_3$." *U. S.* "Sodium Salicylate may be obtained by the interaction of salicylic acid and sodium carbonate. It contains not less than 99.5 per cent. of pure sodium salicylate, $NaC_7H_5O_3$." *Br.*

Salicylus; Sodicus; Salicylate of Soda; Salicylate Neutre de Sodium, *Fr.;* Natrium salicylicum, *P. G.;* Natriumsalicylat, *G.;* Salicilato di sodio, *It.;* Salicilato sodico, *Sp.*

This salt is prepared by mixing 100 parts of pure salicylic acid with sufficient water to form a paste, and then with 104 parts of pure crystallized sodium carbonate (U. S. P. 1890, uneffloresced) in a glass or porcelain vessel; carbon dioxide will be evolved, and sodium salicylate will remain in solution. The liquid may be strained through thoroughly washed muslin, if necessary, and heated in an evaporating dish until the carbon dioxide is expelled. If alkaline to litmus paper, enough salicylic acid must be added to be slightly in excess, and the solution is then evaporated at a low heat to dryness. If the acid be not in excess, the salt will not be white, but gray or lead-colored.

Description and Physical Properties.—"White, microcrystalline powder, or scales, or an amorphous powder. It is colorless or has not more than a faint pink tinge. It is odorless, or has a faint, characteristic odor, and possesses a sweet, saline taste. One Gm. of Sodium Salicylate is soluble in 0.9 cc. of water and in 9.2 cc. of alcohol, at 25° C. It is very soluble in boiling water and in boiling alcohol, and is soluble in 4 parts of glycerin.

"When heated, the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaving a residue of sodium carbonate and carbon. An aqueous solution of Sodium Salicylate (1 in 4) responds to the reactions for sodium, and for salicylates.

"An aqueous solution of Sodium Salicylate (1 in 10) when freshly made is colorless or nearly colorless, and is neutral or slightly acid to litmus paper. Add 1 cc. of hydrochloric acid to a solution of 1 Gm. of Sodium Salicylate in 20 cc. of distilled water, and filter the liquid: the filtrate does not decolorize 2 drops of tenth-normal iodine (*sulphite or thiosulphate*). Add a slight excess of hydrochloric acid to an aqueous solution of the salt (1 in 50), and filter: the filtrate meets the requirements of the test for *heavy metals.*

"**Assay.**—Proceed as directed under the assay for alkali benzoates and salicylates, using about 2 Gm. of Sodium Salicylate, previously dried to constant weight at 100° C. and accurately weighed. Each cc. of half-normal sulphuric acid corresponds to 0.08004 Gm. of $NaC_7H_5O_3$.

"Preserve in well-closed containers, protected from heat and light." *U. S.*

"Small colorless scales, or tabular crystals with a pearly lustre. No odor; taste sweetish, unpleasant, saline. Soluble in 1 part of *water,* but this solution, when allowed to stand, is liable to deposit crystals of the salt containing 6 molecules of water of crystallisation; soluble in 6 parts of *alcohol* (90 per cent.). Solutions neutral or faintly acid to *litmus.* Carbonises when heated, leaving finally a white ash which effervesces with acids and imparts an intense yellow color to flame. *T. Sol. of ferric chloride* colors a dilute solution violet. 2 grammes, heated to redness till gases cease to be evolved, leave an alkaline residue which, when treated with *water,* filtered, and well washed, yields a clear solution requiring for neutralisation not less than 24.8 millilitres of *N/2 solution of sulphuric acid.* When to a concentrated aqueous solution excess of *diluted nitric acid* is added, a precipitate is produced which, collected, washed, and dried, responds to the tests described under 'Acidum Salicylicum,' and the filtrate yields not more than the slightest *reactions* for sulphates or chlorides. *Lead limit* 10 parts per million. *Arsenic limit* 2 parts per million. 50 to 100 grammes kept in a closed vessel for several days do not evolve the slightest odor of phenol. Dissolves without coloration or effervescence in *sulphuric acid* (absence of certain organic impurities and of carbonates)." *Br.*

Sodium salicylate is incompatible with antipyrine, forming, when mixed in powder, a liquid mixture. It is also incompatible with ferric salts. Acids decompose it when in solution, precipitating salicylic acid. The discoloration of sodium salicylate solutions which is often noticed after they have been dispensed is said to be due to the absorption of small amounts of ammonia from the air. (*P. J.*, 1915, 355.)

Uses.—The action of sodium salicylate upon the economy, and its therapeutic use, are precisely those of salicylic acid, except that the salt is not locally irritating, and, being soluble, is more rapidly absorbed. When salicylic acid is administered, it is mostly converted into sodium salicylate before it is absorbed into the blood. One drachm of the salt contains about fifty grains of the acid.

Dose, from ten to thirty grains (0.65–2.0 Gm.).

Off. Prep.—Caffeinæ Sodio-Salicylas, *N. F.;* Elixir Sodii Salicylatis, *N. F.;* Elixir Sodii Salicylatis Compositum, *N. F.;* Elixir Manacæ Compositum, *N. F.;* Elixir Tongæ et Salicylatum, *N. F.;* Liquor Ferri Salicylatis, *N. F.*

SODII SULPHAS. U. S., Br.

SODIUM SULPHATE Sod. Sulph. [Glauber's Salt]

"Sodium Sulphate contains not less than 43.64 per cent. and not more than 48 per cent. of Na_2SO_4, corresponding to not less than 99 per cent. of the crystallized salt [$Na_2SO_4.10H_2O$]." *U. S.* "Sodium Sulphate, $Na_2SO_4,10H_2O$, may be obtained by the interaction of sodium chloride with sulphuric acid." *Br.*

Sulphate of Soda; Sulfas Sodicus (Natricus), Sal mirabile Glauberi; Vitriolated Soda, Glauber's Salt, Sulfate de Sodium Officinal, Sel de Glauber, *Fr.;* Natrium Sulfuricum, *P. G.;* Natriumsulfat, Schwefelsaures Natron, Glaubersalz, *G.;* Solfato di Sodio, *It.;* Sulfato Sodico, Sal admirabile de Glaubero, *Sp.*

Sodium sulphate, in small quantities, is extensively diffused in nature, and is obtained artificially in several chemical operations. It exists in solution in many mineral springs, among which may be mentioned those of Cheltenham and Carlsbad, and it is found combined with calcium sulphate constituting a distinct mineral. It was the *sal mirabile* to which Glauber, the 18th century chemist, attributed such wonderful therapeutic properties, and in consequence of which it is still called *Glauber's salt.*

Immense quantities of sodium sulphate are made by decomposing common salt by sulphuric acid, in the manufacture of soda-ash and sodium carbonate (see *Sodii Carbonas*), in both the Leblanc and the Hargreave's processes. So far from the generated hydrochloric acid being a product of much value, its absorption in a convenient way, so as to avoid the nuisance of its escape into the atmosphere in a gaseous state, is an object of importance to the manufacturer. (See *Acidum Hydrochloricum.*) At Strassfurt sodium sulphate is produced extensively by utilizing the mother liquors from the treatment of carnallite or kilderite, which still contains about 25 per cent. of magnesium sulphate and 50 per cent. of sodium chloride.

The residue of the process for obtaining chlorine by the action of sulphuric acid and manganese dioxide on common salt is a mixture of sodium sulphate and manganous sulphate. Large quantities of this residue are formed in manufacturing chlorinated lime (bleaching powder), and the sodium sulphate in it, roughly purified, supplies a part of the salt consumed in making soda-ash and sodium carbonate.

The process for obtaining ammonium chloride from ammonium sulphate and common salt forms another source of sodium sulphate. By double decomposition, sodium sulphate and ammonium chloride are formed, and by exposing the mixed salts to heat, the ammonium chloride sublimes, and the sodium sulphate remains behind. (See *Ammonii Chloridum.*)

Description and Physical Properties.—"Large, colorless, odorless, transparent, monoclinic prisms, or granular crystals. The salt effloresces rapidly in the air. One Gm. of Sodium Sulphate is soluble in about 1 cc. of water at 25° C. It is insoluble in alcohol but soluble in glycerin. When heated to about 33° C., Sodium Sulphate melts in its water of crystallization and on continuing the heat, maintaining it at 100° C., it loses all of its water of crystallization (about 56 per cent.). At a red heat, the anhydrous salt fuses without decomposition.

"An aqueous solution of Sodium Sulphate (1 in 20) responds to the reactions for sodium, and for sulphates.

"An aqueous solution of the salt (1 in 10) is neutral to litmus paper. An aqueous solution of the salt meets the requirements of the test for *heavy metals.* An aqueous solution of the salt meets the requirements of the test for *arsenic.*

"**Assay.**—Dissolve about 1 Gm. of Sodium sulphate, accurately weighed, in 250 cc. of distilled water, acidulate the solution with 1 cc. of hydrochloric acid, and heat it to boiling. Gradually add an excess of hot barium chloride T.S., heat for thirty minutes on a water bath, collect the precipitate of barium sulphate on a filter, wash it until it is free from chlorides, then dry, ignite, and weigh. The weight of the barium sulphate thus obtained, multiplied by 0.6086, indicates its equivalent in Na_2SO_4. Each Gm. of Sodium Sulphate corresponds to not less than 0.717 Gm. and not more than 0.789 Gm. of $BaSO_4$.

"Preserve in well-closed containers, in a cool place." *U. S.*

"In transparent monoclinic prisms; efflorescent. Taste bitter, saline. Soluble in 3 parts of *water;* insoluble in *alcohol* (90 per cent.). Loses about 55.9 per cent. of its weight when dried at 100° C. Yields the *reactions* characteristic of sodium and of sulphates. 1 gramme dissolved in *water* acidified with *hydrochloric acid* yields, on the addition of excess of *solution of barium chloride,* a white precipitate which, washed and dried, weighs about 0.724 gramme. Yields no characteristic *reactions* for iron, magnesium, potassium, ammonium, or carbonates, and not more than the slightest *reactions* for chlorides. *Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million." *Br.*

When recently prepared it is beautifully transparent; but on exposure to the air it effloresces, and the crystals become covered with an opaque white powder. After long exposure it undergoes complete efflorescence, and falls into powder with loss of more than half its weight. A supersaturated solution of sodium sulphate will remain without crystallizing at ordinary temperatures, even though containing several times the weight of the salt that will be dissolved at the same degree of heat. But the solution instantly forms into a crystalline mass upon adding to it a fragment of the same salt crystallized, or other substances that have been exposed to the air, or upon abruptly placing it in contact with the air.

When crystallized sodium sulphate is subjected to heat it dissolves in its water of crystallization, then dries, and afterwards by the application of a red heat melts with the loss of 55½ per cent. of its weight. It is incompatible with potassium carbonate, calcium chloride, the salts of barium, lead acetate and subacetate, and with silver nitrate if the solutions are strong.

Uses.—Sodium sulphate in doses of from half an ounce to an ounce (15.5–31 Gm.) is an efficient hydragogue cathartic; in smaller doses, an aperient and diuretic. When in an effloresced state, the dose must be reduced one-half, on account of its having lost about one-half of its weight of water. Sodium sulphate is much less used than formerly, having been almost entirely superseded by magnesium sulphate, which is less disagreeable to take and milder in its action. Its nauseous taste, however, may be disguised by the admixture of a little lemon juice or cream of tartar, or by the addition of a few drops of sulphuric acid. D. de Luca has found sodium sulphate remarkably efficient in removing *stains* or *opacity* of the *cornea,* if applied in the form of powdered crystals directly to the eyeball twice daily. (*J. P. C.,* Sept., 1867.) The only uses of sodium sulphate in the arts are to make sodium carbonate and some kinds of glass.

Dose, two drachms to an ounce (7.7–31 Gm.).

SODII SULPHAS EFFERVESCENS. Br.

EFFERVESCENT SODIUM SULPHATE

Sodæ Sulphas Effervescens; Effervescent Sulphate of Soda; Natrium Sulfuricum Effervescens; Brausendes Natriumsulfat, *G.*

"Sodium Sulphate, in crystals, 500 *grammes;* Sodium Bicarbonate, in powder, 500 *grammes;* Tartaric Acid, in powder, 270 *grammes;* Citric Acid, in powder, 180 *grammes.* Dry the Sodium Sulphate until it has lost about 55 per cent. of its weight; powder the dried salt, and mix it with the other ingredients. Place the whole in a dish or pan of suitable form, heated to between 90° and 105° C. When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 55° C. The product weighs about one thousand grammes." *Br.*

It is used as an effervescent laxative, in the *dose* of from one-fourth to one-half ounce (7.7–15.5 Gm.) dissolved in cold water and taken while effervescing.

SODII SULPHIS. Br.

SODIUM SULPHITE

"Sodium Sulphite may be obtained by the interaction of sulphurous acid and sodium carbonate. It contains not less than 94 per cent. of pure sodium sulphite, $Na_2SO_3,7H_2O$." *Br.*

Natrium Sulfurosum, Sulfis Sodicus (Natricus), Sulfite de Soude, *Fr.;* Natriumsulfit, Schwefligsaures Natron, *G.*

This salt may be prepared by passing sulphurous acid gas into a solution of sodium carbonate, and evaporating out of contact of the air. The sulphurous acid unites with the soda of the carbonate to form sodium sulphite, and the carbon dioxide escapes. After sufficient concentration, the solution is allowed to cool, and the salt crystallizes. A better way, however, is to dissolve a convenient weight of sodium carbonate in a small quantity of water, then pass the sulphurous acid gas through the solution until it is completely saturated, and acid sodium sulphite is formed. The addition of an equal weight of sodium carbonate forms a solution of the neutral sulphite, which is to be evaporated and crystallized. On exposure the salt gradually changes into a sulphate.

Sulphuric acid added to the solution gives rise to an odor of burning sulphur, owing to the escape of sulphurous acid, and the liquid remains transparent, indicating the absence of calcium. For methods of determining sodium carbonate in sodium sulphite by C. E. Caspari and M. R. Moffat the reader is referred to *Proc. A. Ph. A.,* 1902; also *West. Drug.,* 1904, 59. Sodium sulphite has been replaced in the U. S. P. by the more stable exsiccated salt, which see.

Properties.—"Colorless, transparent, monoclinic prisms, efflorescent in dry air. Inodorous; taste saline and sulphurous. Soluble in 2 parts of *water;* insoluble in *alcohol* (90 per cent.). Yields the *reactions* characteristic of sodium and of sulphites. Aqueous solution neutral or faintly alkaline to *litmus;* on the addition of *hydrochloric acid* evolves sulphur dioxide, but does not become cloudy (absence of thiosulphate). 0.3 gramme dissolved in 30 millilitres of *N/10 solution of iodine* yields a solution which requires for complete decolorisation not more than 7.6 millilitres of *N/10 solution of sodium thiosulphate. Arsenic limit* 5 parts per million." *Br.*

Under the name of *Sodii Sulphis Exsiccatus* (*Exsiccated Sodium Sulphite*) the U. S. IX recognized sodium sulphite practically the same as that of the British pharmacopœia and defined it as containing "not less than 90 per cent. of Na_2SO_3 (126.07)." *U. S. IX.*

This salt may be readily prepared from the crystallized salt by heating the latter at a temperature slightly above 100° C. until an anhydrous residue of constant weight remains. It is more uniform in water content than the crystalline salt.

It was described as follows: "Exsiccated Sodium Sulphite occurs as a white powder; odorless, and having a cooling, saline, sulphurous taste Exposed to the air, it is slowly oxidized to sulphate. One Gm. of Sodium Sulphite dissolves in 3.2 mils of water at 25° C.; sparingly soluble in alcohol. An aqueous solution of the salt (1 in 10) is alkaline to litmus. At a red heat, the salt fuses to a reddish-yellow mass of sodium sulphate and sodium sulphide. To a non-luminous flame the salt imparts an intensely yellow color. Upon the addition of hydrochloric acid to the salt, sulphur dioxide is liberated, which is recognized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. held in the escaping gas. Dissolve 1 Gm. of Exsiccated Sodium Sulphite in 10 mils of diluted hydrochloric acid and heat the solution sufficient to expel the gases; the liquid does not become turbid (*thiosulphate*). Dissolve 1 Gm. of the salt in 20 mils of diluted hydrochloric acid, evaporate the solution to dryness, and dissolve the residue in 50 mils of distilled water. Ten mils of this solution does not respond to the Test for heavy metals. Add 3 mils of nitric acid to 5 mils of an aqueous solution of the salt (1 in 25), cautiously evaporate the solution to dryness on a water bath, and treat the residue with a few cc. of distilled water and filter the liquid. On evaporating the filtrate and washings to dryness, this residue meets the requirements of the Test for arsenic.

"**Assay.**—Add about 0.3 Gm. of Exsiccated Sodium Sulphite, accurately weighed, to 50 mils of tenth-normal iodine V.S. in a glass-stoppered flask, agitate the mixture until complete solution results and titrate with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 90 per cent. of Na_2SO_3.

"Each mil of tenth-normal iodine V.S. used corresponds to 0.006304 Gm. of Na_2SO_3. Each gramme of Exsiccated Sodium Sulphite corresponds to not less than 142.8 mils of tenth-normal iodine V.S." *U. S. IX.*

A. H. Clark (*D. C.,* 1916, p. 376) has reported at length upon the keeping qualities of the anhydrous salt in comparison with the hydrated crystalline form. His conclusions are in favor of the greater stability of the dehydrated salt.

Uses.—According to the experiments of L. Pfeiffer (*A. E. P. P.,* xxvii), the sulphites are capable of causing death by paralyzing the heart and also the respiratory and other motor nerve centers, but are so rapidly and completely changed into the sulphates that unless given in enormous amount they exert very little influence upon the system; 96.5 per cent. of the sulphite was regained from the urine as a sulphate, and 86 per cent. passed out in five hours after ingestion. But, according to Kionka (*D. M. W.,* 1902, xxviii, p. 89), even in doses comparable to those used in the preservation of food the prolonged use produced in dogs serious symptoms of intoxication. Although the experiments of Sternberg have demonstrated that sodium sulphite has no germicidal powers, it appears to be distinctly toxic to the more highly organized fungoid parasites. It has been used in cases of *yeasty vomiting* with remarkable success. The matter vomited in these cases contains two microscopic fungi, called *Sarcina ventriculi* and *Torula cerevisiæ.* The remedy was first used at the suggestion of Graham of London, who supposed that the sulphurous acid, necessarily extricated from the salt in the stomach by the acid of the yeasty matter, would destroy the parasites. Sodium sulphite is sometimes used locally, especially in that species of *aphthous sore mouth* which is attributed to a parasitic vegetable. The wash may be made of a drachm of the salt to a fluidounce of water. It is said that the solution acts with surprising rapidity, a single application of it sometimes removing the disease in 24 hours. Astrié, an Italian physician, has proposed this salt as a remedy for the constitutional effects of mercury, when used in excess, on the ground that it has the power of rendering the metal soluble. It also has been largely given internally as an antizymotic (see *Sodii Thiosulphas*), but without general success.

Dose, of the official sodium sulphite, from, eight to thirty grains (0.5–2.0 Gm.).

SODII THIOSULPHAS. U. S.

SODIUM THIOSULPHATE Sod. Thiosulph
["Sodium Hyposulphite"]

"Sodium Thiosulphate contains not less than 63.07 per cent. and not more than 67.48 per cent. of $Na_2S_2O_3$, corresponding to not less than 99 per cent. of the crystallized salt [$Na_2S_2O_3.5H_2O$]." *U. S.*

Hyposulphite of Soda; Natrum Subsulfuresum (Hyposulfurosum); Hyposulphis Sodicus; Thiosulphas Natricus; Hyposulphite de Sodium, *Fr. Cod.;* Sulfite Sulfuré de Soude, *Fr.;* Natrium thiosulfuricum, *P. G.;* Natriumthiosulfat, Unterschwefligsaures Natron, *G.;* Hiposulfito sodico, *Sp.*

This salt is used in the United States and British Pharmacopœia as a test, and for the formation of the *Volumetric Solution of Sodium Thiosulphate.* It is found only in the Appendix of the Br. It is readily prepared, according to Walchner, by mixing a pound of dry sodium carbonate, in fine powder, with five ounces of sulphur, heating the mixture gradually in a porcelain vessel until the sulphur melts, and stirring the agglutinated mass, still kept hot, in order that every portion of it may come in contact with the air. The sodium sulphide first formed is thus converted into sodium sulphite. This is dissolved in water, and the filtered solution being boiled with sulphur becomes one of sodium thiosulphate, from which, after filtration and concentration, the salt is deposited in crystals. The latter part of the reaction is as follows:

$$Na_2SO_3 + S = Na_2S_2O_3$$

It may be obtained also by digesting the solution of sodium sulphite at a high temperature, but short of ebullition, with finely divided sulphur. It is made also by oxidizing sodium hydrosulphide, according to the following reaction:

$$2NaHS + 2O_2 = 2Na_2S_2O_3 + H_2O$$

It is also obtained as a by-product from the sulphur-containing residues of the LeBlanc soda process which is still employed in some parts of Europe.

Thiosulphuric acid exists only in combination, and its salts were formerly considered simply as sulphuretted sulphites. The true *hyposulphurous acid,* according to theory, would be H_2SO_2, while $H_2S_2O_3$ is more properly *thiosulphuric* acid, as it differs from sulphuric acid by the replacement of one oxygen atom by one sulphur atom.

Inasmuch as Schützenberger discovered the true hyposulphurous acid, H_2SO_2, exact chemical usage would demand that we give the distinguishing name thiosulphuric to what was formerly called hyposulphurous. Schützenberger himself called the newly-discovered acid *hydrosulphurous,* but this is not characteristic, and the correct name for "sodium hyposulphite" is sodium thiosulphate.

Description and Physical Properties.—"Colorless, odorless, transparent, monoclinic prisms. It is stable in the air below 33° C., but efflorescent in dry air above that temperature. It is slightly deliquescent in moist air. One Gm. of Sodium Thiosulphate is soluble in 0.5 cc. of water at 25° C. It is insoluble in alcohol. When rapidly heated, the salt liquefies. When heated slowly until it is effloresced, and afterwards at 100° C., it undergoes partial decomposition, loses all of its water of crystallization, and at about 220° C. is decomposed, sulphur being liberated, while a residue of sodium sulphide and sodium sulphate remains.

"An aqueous solution of Sodium Thiosulphate responds to the reactions for sodium, and for thiosulphates. An aqueous solution of Sodium Thiosulphate readily dissolves many compounds of silver (chloride, bromide, iodide, oxide, etc.) and discharges the color of solution of iodine or of starch iodide. The addition of hydrochloric acid to an aqueous solution of Sodium Thiosulphate produces a white precipitate of sulphur (distinction from *sulphite or bisulphite*).

"An aqueous solution of the salt (1 in 10) is neutral or faintly alkaline to litmus paper. An aqueous solution of Sodium Thiosulphate (1 in 20) is not rendered turbid by the addition of ammonium oxalate T.S. (*calcium*). Add 10 cc. of diluted hydrochloric acid to 1 Gm. of the salt, evaporate to dryness on a water bath, heat the residue with 50 cc. of distilled water, and filter: a 10 cc. portion of this filtrate meets the requirements of the test for *heavy metals.* Add 3 cc. of nitric acid to 5 cc. of an aqueous solution of the salt (1 in 25), evaporate the solution cautiously to dryness on a water bath, treat the residue with a few cc. of distilled water, filter the liquid, and evaporate the filtrate and washings to dryness: the residue meets the requirements of the test for *arsenic.*

"**Assay.**—Dissolve about 1 Gm. of Sodium Thiosulphate, accurately weighed, in 20 cc. of distilled water, and titrate with tenth-normal iodine, starch T.S. being used as indicator. Each cc. of tenth-normal iodine corresponds to 0.01581 Gm. of $Na_2S_2O_3$.

"Preserve in well-closed containers." *U. S.*

Its solution dissolves silver chloride and all water-insoluble compounds of that metal, except the sulphide, and that resulting from the decomposition of a silver salt by light. It has a similar relation to the insoluble salts of lead. Though without action on potassium iodide, it dissolves iodine, decomposes iodic acid with liberation of iodine, and destroys the blue color of starch iodide. In dissolving iodine it forms with it sodium iodide and sodium tetrathionate, as represented by the formula

$$2(Na_2S_2O_3) + I_2 = (NaI)_2 + Na_2S_4O_6$$

Its relations to iodine render it valuable as a means of estimating the quantity of free iodine, for which purpose it is used in the Pharmacopœias in the form of a volumetric solution.

In consequence of its peculiar solvent properties, it is much used in photography. The photographers employ it for the purpose of dissolving the unchanged silver iodide, or bromide, from the plate after the action of the light, and thus fixing the image already formed. It is also largely used as an "*antichlor*" in paper manufacture, to free the paper pulp from the excess of chlorine used in the bleaching. One of the most delicate tests is that of iodine with starch. The blue color produced by the mixture of very small quantities of these two substances in solution is instantly discharged by a solution containing a trace of the thiosulphate. If zinc or iron is dipped into an acidified solution of the thiosulphate, the liberated hydrogen at once reduces the sulphurous oxide which is in the solution to hydrogen sulphide, recognizable by lead acetate paper. This test will serve to show even traces of thiosulphate.

Uses.—In 1920 Ravaut of Paris recommended the use of sodium thiosulphate in the treatment of the *dermatitis* which sometimes follows arsphenamine injections. The value of the treatment has been confirmed by several investigators. Groehl and Myers (*T. G.*, 1924, xlviii, p. 691) found that after the intravenous injection of sodium thiosulphate in these cases there was a marked increase in the amount of arsenic in the urine and attribute the beneficial effect to stimulated excretion. Kuhn and Loevenhart (*J. P. Ex. T.*, 1925, xxv, p. 160) find, however, that sodium thiosulphate delays the elimination of arsenic; but that to a limited extent, at least, it protects animals against the toxic properties of this poison. They find that it also lowers the therapeutic efficiency of the organic arsenicals and conclude that its effect is due to the formation in the body of a less toxic compound with arsenic. Dennie and MacBride (*J. A. M. A.*, 1924, lxxxiii, p. 2082) recommend the internal use of sodium thiosulphate in other metallic poisonings, such as *lead* and *mercury*, but present no convincing evidence of its value.

Sodium thiosulphate is also useful as a topical application in many forms of *skin diseases.* Its beneficial effect is probably due in part to a reducing action, but in some, as in *ivy poisoning,* it appears to exercise an antipruritic action. Trousseau (*R. T.*, 1905, p. 136) has recommended sodium thiosulphate in five per cent. solution as a topical application in *blepharitis* and *conjunctivitis.*

Dose, ten to twenty grains (0.65–1.3 Gm.), three times a day simply dissolved in water, or in the form of syrup. For external use a drachm may be dissolved in a fluidounce of water.

SODIUM

SODIUM

"The metal sodium as met with in commerce. It should be preserved in well-stoppered bottles under mineral naphtha." *Br.*, 1898.

Sodium, *Fr.;* Natrium, Natronmetall, *G.;* Sodio, *It.*, *Sp.*

The metal sodium was discovered by Sir Humphry Davy in 1807, who obtained it in small quantity by decomposing soda by the agency of galvanic electricity. Sodium was formerly prepared on a large scale by igniting an intimate mixture of dry sodium carbonate, coal and chalk. The amount of metal obtained by this method is, however, not over 40 per cent. of the theoretical result. A much improved process was next brought out by Castner (*J. Soc. Chem. Ind.*, 1887, 174), in which an iron carbide, or a mixture of fine iron and coke, is used to reduce the caustic soda, according to the reaction:

$$6NaOH + FeC_2 = 2Na_2CO_3 + 6H + Fe + 2Na$$

The reduction of the sodium hydroxide takes place at a temperature of about 800° C., and is carried out in steel crucibles, each of which holds 5.6 kilos of sodium hydroxide and 1.97 kilos of carbide. The product of the reaction consists of about 4.85 kilos of sodium carbonate and 0.933 kilo of metallic sodium. This latter collects in a receiver connected with the top of the crucible, while the sodium carbonate is dissolved out from the residue and is causticized preparatory to being used again. This process in turn has been replaced by the electrolytic processes. The most successful of these is that of Castner, who uses an electrolyte of fused sodium hydroxide in an iron pot or crucible with an anode of iron and a cathode of copper. The sodium is reduced at a comparatively low temperature, and is ladled from the vessel into moulds. The process is carried out at present on a large scale by the Niagara Electro-Chemical Co., and at Oldbury, England, and several places in Germany.

Sodium is a soft, malleable, ductile solid, of a silver-white color. It possesses the metallic luster in a high degree, when protected from the action of the air, by which it is quickly tarnished and oxidized. Its sp. gr. when fused is 0.97 at 20° and 0.74 at the fusion point, which is 97.6° C. Its chemical affinities resemble those of potassium, but are less energetic. Like potassium, it has a strong attraction for oxygen. When thrown upon cold water it instantly fuses into a globule without inflaming, and traverses the surface in different directions with rapidity; on warm water it inflames. In both cases the water is decomposed, hydrogen is liberated, and sodium hydroxide generated. Like potassium, if exposed with a bright surface to the air, it undergoes a slow combustion, which renders it luminous in the dark. It combines with oxygen to form the monoxide, Na_2O, and a peroxide, Na_2O_2. This latter oxide is always formed when the metal is burned in the open air.

It is officially described as "A soft metal, rapidly oxidizing in the air, but showing a bright metallic surface when freshly cut. It violently attacks water or alcohol (90 per cent.), with evolution of hydrogen, little or no insoluble matter remaining. It imparts an intense yellow color to flame. Each gramme very cautiously added to water affords a solution which should require for neutralisation at least 42.6 cubic centimetres of the volumetric solution of sulphuric acid." *Br.*

Sodium salts are characterized by communicating to the blowpipe flame a rich yellow color which is the most distinguishing analytical characteristic of this element. Sodium salts are not readily precipitable. The least soluble salt is the pyroantimoniate, $Na_2H_2Sb_2O_7$, which requires 350 parts of cold water for solution. According to Ball (*Chem. Trans.,* 1909, 2126) a solution of bismuth potassium nitrite containing calcium nitrite forms a reagent capable of detecting as little as 0.01 mgm. of sodium, even in the presence of an excess of potassium, by the formation of a yellow precipitate.

$$Na_2O + H_2O = 2NaOH$$

For description of sodium dioxide, see under *Peroxides,* Part II.

Uses.—Sodium is the most nearly inert physiologically of all the elements. It is, therefore, the base of choice when it is desired to obtain the effects of various acid ions. For the effects of massive doses of sodium see under *Sodii Carbonas.*

SOLANUM. N. F.

SOLANUM Solan. [Horse-Nettle Berries]

"Solanum is the air-dried, ripe fruit of *Solanum Carolinense* Linné (Fam. *Solanaceæ*). Solanum contains not more than 5 per cent. of immature fruit and not more than 2 per cent. of foreign organic matter." *N. F.*

Horse Nettle; Sand Brier; Poisonous Potato; Apple of Sodom.

The horse nettle is a common perennial weed in waste places and sandy soil throughout the whole of the Eastern United States. Its erect, branched stem, about 2 or 3 feet in height, is armed with stout yellowish prickles which are also on the veins of the leaves. The corolla is violet and with the exserted yellow stamens makes an attractive contrast of color; the leaves are oblong, ovate, obtusely toothed or lobed; the fruit an orange yellow berry about ⅓ to ¾ of an inch in diameter.

Description and Physical Properties.—"*Unground Solanum.*—Globose, slightly depressed, somewhat shriveled and wrinkled in drying, from 0.8 to 2 cm. in diameter, orange-yellow, glabrous, fleshy, two-celled, many-seeded, calyx and pedicel usually persistent; calyx stellate pubescent, deeply incised, the five subdivisions ovate or ovate-lanceolate, acuminate and enclosing half or more of the berry; seeds orbicular, flat, yellow, smooth, shining. Odor pepper-like; taste bitter and acrid.

"*Powdered Solanum.*—Brownish; numerous fragments of seed coat composed of cells from 0.138 to 0.250 mm. in length with very sinuous, yellowish, lignified walls about 0.015 mm. in thickness; fragments of epicarp composed of cells with thick yellowish walls and a yellowish amorphous content; portions of sarcocarp composed of thin-walled, more or less collapsed cells some containing nearly spheroidal starch grains up to 0.012 mm. in diameter; tracheæ narrow with spiral or reticulate thickenings; occasional microcrystals." *N. F.*

For study of microscopic structure, see Johnson, *A. J. P.,* 1897, lxix, 76. G. A. Krauss (*A. J. P.,* 1890, p. 601 and 1891, p. 216) found two active principles corresponding probably to *solanine* and *solanidine* (see Part II), together with a characteristic organic acid to which he gives the name *solanic acid.* J. U. Lloyd believes that the alkaloid in this plant is not identical with solanine, and proposes to call it *solnine.* (*A. J. P.,* 1894, 161, and 1897, 108.)

Uses.—E. Q. Thornton (*T. G.,* xii, 1896) finds that in frogs this solanum produces stupor with tetanic spasms, not prevented by section of the cord. It is said to have long been used by the negroes of the South in the treatment of the so-called falling sickness, and in 1889 it was recommended by J. L. Napier as of value in *epilepsy.* H. C. Wood found that, although when given by itself its usefulness is very limited, as an adjuvant to the bromides it lessens the size of the doses necessary to keep the convulsions in check. Not less than a fluidrachm (3.75 cc.) of the fluidextract should be given three times a day. No unpleasant effects have been produced by it.

Dose, from thirty to sixty grains (2–4 Gm.).

Off. Prep.—Fluidextractum Solani, *N. F.*

SPIRITUS

SPIRITS

Alcoolats, *Fr.;* Geiste, *G.;* Spirito, *It.;* Espiritu, Solucion Alcoholica, *Sp.*

Spirits, as the term is here used, are alcoholic solutions of volatile principles formerly procured by distillation, but now frequently prepared by simply dissolving the volatile substance or substances in alcohol. The spirits as a rule are prepared by simple solution of the active substance in alcohol. A few are prepared by distillation as *Spiritus Frumenti* and *Spiritus Vini Vitis.* Some are therapeutic agents of value, others are employed merely as flavoring agents. These latter are sometimes confused with the "flavoring extracts" or "essences" used in culinary practice, but as a rule the official spirits are much stronger than the flavoring extracts of the same name, and in some cases, notably *Spiritus Amygdalæ* contain constituents which are not suitable for use in food products.

SPIRITUS ÆTHERIS. Br.

SPIRIT OF ETHER Sp. Æth. [Hoffmann's Drops]

Liquor Anodynus Mineralis Hoffmanni; Ether officinal alcoolisé, Ether sulfurique alcoolisé, Liqueur d'Hoffmann, *Fr.;* Spiritus Æthereus, *P. G.;* Aetherweingeist, Hoffmannsche Tropfen, *G.;* Etere con alcool, Liquore anodino di Hoffmann, *It.;* Eter sulfurico alcoholizado, Licor anodino mineral de Hoffmann, *Sp.*

"Ether, 500 *millilitres;* Alcohol (90 per cent.), 1000 *millilitres.* Mix. Specific gravity 0.802 to 0.806." *Br.*

This preparation is merely ether diluted with about twice its volume of alcohol. Because of the infrequency of its use and the simplicity of its preparation it was wisely omitted at the last revision of the U. S. The corresponding preparation of the German Pharmacopœia contains less ether, being made of one part of ether to three parts of alcohol, both by weight.

The spirit of ether is used chiefly as a carminative in *flatulent colic.* Although not so frequently employed as the former U. S. P. *compound spirits of ether,* which is now official in the N. F. (see *Spiritus Ætheris Compositus,* Part III), it has all the therapeutic virtues of that preparation. The Compound Spirit of Ether is commonly known as *Hoffmann's Anodyne.*

Dose, one to three fluidrachms (3.75–11.25 cc.).

SPIRITUS ÆTHYLIS NITRITIS.
U. S. (Br.)

SPIRIT OF ETHYL NITRITE Sp. Æth. Nitrit. [Spiritus Ætheris Nitrosi U. S. P. IX, Spirit of Nitrous Ether, Sweet Spirit of Niter]

"Spirit of Ethyl Nitrite is an alcoholic solution of ethyl nitrite containing not less than 3.5 per cent. and not more than 4.5 per cent. of $C_2H_5NO_2$." *U. S.* "Spirit of Nitrous Ether is an alcoholic solution containing not less than 1.52 or more than 2.66 per cent. by weight of ethyl nitrite, together with aldehyde and other allied substances. It should be kept in well-closed vessels; preferably in a cool dark place, and in small amber bottles." *Br.*

Spiritus Ætheris Nitrosi, *Br.;* Spiritus Nitri Dulcis; Spiritus Ætheris Nitrici; Spiritus Nitrico-æthereus; Ætheris Nitrosi Spiritus; Alcoholum Nitricum Æthereum; Ether Azoteux Alcoolisé, Liqueur anodine nitreuse, *Fr.;* Versüsster Salpetergeist, *G.;* Etere nitroso officinale, Spirito d'etere nitroso, *It.;* Espiritu de nitro dulce, *Sp.*

"Nitric Acid, 150 *millilitres;* Sulphuric Acid, 100 *millilitres;* Copper of commerce, in wire or turnings, 100 *grammes;* Alcohol (90 per cent.), *a sufficient quantity.* To one thousand millilitres of the Alcohol add gradually the Sulphuric Acid, and then one hundred and twenty-five millilitres of the Nitric Acid, stirring constantly. Transfer the mixture to a retort or flask, in which the fragments of copper have been placed, and to which is attached an efficient condenser with a receiver containing one thousand millilitres of the Alcohol. Surround the receiver with ice-cold water and distil gently at a temperature which is at first about 77° C., and rises to 80° C., but does not exceed 82° C., until the volume of liquid in the receiver has been increased to sixteen hundred millilitres. Then allow the contents of the retort to cool, introduce the remaining twenty-five millilitres of Nitric Acid, and resume the distillation as before, until the liquid in the receiver has been increased to seventeen hundred millilitres. Mix this liquid with one thousand millilitres of the Alcohol, or with as much as will make the product contain 2.66 per cent. by weight of ethyl nitrite when tested as described in the following paragraph." *Br.*

The U. S. P. X does not give any method for the preparation of this spirit. That which was previously official was based upon decomposition of sodium nitrate with sulphuric acid as follows: "Sodium Nitrite, *one hundred grammes;* Sulphuric Acid, *forty mils;* Monohydrated Sodium Carbonate, *six-tenths of a gramme;* Potassium Carbonate, completely deprived of water by heating, *three grammes;* Alcohol, Water, each, *a sufficient quantity.* Mix the sulphuric acid with *one hundred and twenty mils* of water, cool the liquid, add *eighty-five mils* of alcohol previously diluted with an equal volume of water, and introduce the solution into a 1000 mil flask, surrounded by a mixture of ice and water. Dissolve the sodium nitrite in *two hundred and eighty mils* of water, filter, and, having poured the filtrate into a separatory funnel, allow the liquid to slowly drop into the flask containing the acid mixture. When all has been added and the reaction is complete, allow any crystals which may have formed to settle at the bottom of the flask, and decant the cold mixture of ethyl nitrite and aqueous solution quickly to the previously cooled separatory funnel, and draw off and discard the aqueous liquid. Wash the separated ethyl nitrite, first with *twenty mils* of ice-cold water, and then remove any traces of acid by washing it with *fifteen mils* of ice-cold water, in which the monohydrated sodium carbonate has previously been dissolved. Carefully separate the ethyl nitrite from the aqueous liquid, and agitate it in a well-stoppered botle with the potassium carbonate to remove traces of water. Then cool the liquid, decant, and pour the ethyl nitrite immediately into a tared bottle containing *five hundred grammes* of alcohol. Ascertain the weight of the ethyl nitrite poured in the alcohol by noting the increase in weight of the tared bottle and contents, and then add enough alcohol to make the mixture weigh *twenty-two times* the weight of the ethyl nitrite added. Lastly, transfer the product to small, well-stoppered, dark, amber-colored bottles, and keep these in a cool place, remote from fire." *U. S. IX.*

The official spirit of nitrous ether is a mixture of nitrous ether or ethyl nitrite, $C_2H_5NO_2$, and alcohol (rectified spirit). For many years, spirit of nitrous ether was made by acting on alcohol with nitric acid, and the present British process is constructed on this plan. The U. S. P. VIII and IX processes differed essentially; in these, the use of nitric acid was abandoned, sodium nitrite being substituted as the source of the nitrous compound. Ethyl nitrite is readily generated by the reaction of nitric acid with alcohol; and it matters not whether the alcohol be mixed with nitric acid directly, or with the materials for generating it, namely, niter and sulphuric acid.

Many processes have been suggested for the preparation of this spirit by the retail pharmacist. All are equally subject to the criticism that they are difficult to carry out and none is capable of yielding a product which does not require assay and subsequent adjustment of strength. The appearance of the concentrated product in small sealed units, capable of easy use and affording a product of uniform strength has removed the necessity for an official process for this spirit.

Full details of former methods will be found in *U. S. D.*, 20th ed., p. 1049.

The reaction in the U. S. P. IX process may be expressed as follows:

$$2C_2H_5OH + 2NaNO_2 + H_2SO_4 = 2C_2H_5NO_2 + Na_2SO_4 + 2H_2O$$

Alcohol, sodium nitrite, and sulphuric acid when brought in contact yield ethyl nitrite, sodium sulphate, and water.

The nitric acid process may be explained as follows: One molecule of nitric acid, by reacting with one molecule of alcohol, forms one molecule of nitrous acid, one molecule of aldehyde, and one molecule of water, thus:

$$HNO_3 + C_2H_6O = HNO_2 + C_2H_4O + H_2O$$

The nitrous acid, as soon as formed, reacts with a second molecule of alcohol, so as to form one molecule of nitrous ether or ethyl nitrite, with separation of one molecule of water, according to the reaction:

$$C_2H_5.OH + HNO_2 = C_2H_5NO_2 + H_2O$$

In the process of the British Pharmacopœia the nitric acid is converted into nitrous acid by the reducing action of metallic copper and sulphuric acid, the reaction being:

$$HNO_3 + Cu + H_2SO_4 = HNO_2 + CuSO_4 + H_2O$$

The nitrous acid now reacts with the alcohol as in the previous reaction, so as to produce the nitrous ether. The object of using the sulphuric acid is to economize the nitric acid.

The present British formula rejects the sodium nitrite process for the preparation of the spirit, but introduces under *Liquor Ethyl Nitritis* a solution made by decomposing sodium nitrite in the presence of alcohol, and diluting the ethyl nitrite produced, with alcohol containing a little glycerin. It is unfortunate that both preparations were not made of the same strength, the solution containing 3 per cent., the spirit only 2 per cent., of ethyl nitrite; the *solution* contains no aldehyde, but the *spirit* is permitted to contain aldehyde and other substances.

Properties of Ethyl Nitrite.—Pure ethyl nitrite is pale yellow, has a pleasant ethereal and somewhat apple-like odor. It boils at 18° C., and has the sp. gr. 0.900 at 15.5° C. The density of its vapor is 2.627. Litmus is not affected by it. When it is mixed with an alcoholic solution of potassium hydroxide, potassium nitrite and alcohol are formed, without producing a brown color, showing the absence of aldehyde. It is soluble in 48 parts of water, and in all proportions in alcohol or rectified spirit. It is highly inflammable, and burns with a white flame without residue.

Ethyl nitrite in hermetically sealed glass tubes is found in commerce, affording a ready means of preparing small quantities of spirit of nitrous ether as referred to previously. The concentrated product deteriorates on keeping; as pure ethyl nitrite boils at 18° C., the tubes should be cooled and opened and the liquid immediately diluted with the proper quantity of alcohol to make spirit of nitrous ether, or they should be kept in a cool place until used. Clarence M. Kline, of Philadelphia, originated this method of protecting ethyl nitrite. In its pure and concentrated state it is never used in medicine.

Description and Physical Properties.—"A clear, mobile liquid of a pale yellow or faintly greenish-yellow tint. It has a fragrant, ethereal, pungent odor free from acridity, and a sharp, burning taste. It is volatile and inflammable, and rapidly decomposes on exposure to light and air. When freshly prepared or even after being kept for some time with but little exposure to light and air, it is neutral to dry litmus paper. When long kept or after having been exposed to light and air, it acquires an acid reaction. Specific gravity: not above 0.823 at 25° C.

"Immerse a test tube half filled with the Spirit in a water bath heated to 65° C. until it has acquired that temperature: the Spirit distinctly boils upon the addition of a few small pieces of broken glass. Effervescence does not result when a crystal of potassium bicarbonate is added to 5 cc. of the Spirit (*free acid*). Mix 10 cc. of the Spirit with 5 cc. of potassium hydroxide T.S. previously diluted with 5 cc. of distilled water: the mixture assumes a yellow color which does not turn decidedly brown within twelve hours (*aldehyde*).

"Preserve in small, well-stoppered, dark amber-colored bottles, in a cool, dark place, remote from fire." *U. S.*

"A transparent liquid, having a very faint yellowish tinge. Peculiar penetrating apple-like odor; taste characteristic. Specific gravity 0.838 to 0.842. When spirit of Nitrous Ether is carefully poured on an acidified strong aqueous solution of *ferrous sulphate* contained in a test-tube, a deep olive-brown coloration is produced at the surface of contact of the two liquids, widening as the tube is gently shaken. Does not effervesce, or only very slightly, when shaken with *sodium bicarbonate* (limit of acid). 10 millilitres mixed with 5 millilitres of *N/1 solution of sodium hydroxide* and 5 millilitres of *water* assume a yellow color, which does not become brown on standing twelve hours (limit of aldehyde). 1 volume shaken briskly at intervals during five minutes in a brine-charged nitrometer, with 1 volume of *solution of potassium iodide* and 1 volume of *diluted sulphuric acid,* yields at 15.5° C. and normal pressure not less than 4 or more than 7 volumes of nitric oxide gas, corresponding to not less than 1.52 or more than 2.66 parts by weight of ethyl nitrite in 100 parts by weight of the Spirit." *Br.*

Spirit of nitrous ether, when made by the nitric acid process, is never quite free from aldehyde, and, if the distillation be too long continued it is prone to contain a good deal of this substance, which afterwards becomes acetic acid by absorbing oxygen. The change goes on rapidly if the preparation be insecurely kept. Aldehyde, if in considerable proportion, may be detected by its imparting a pungent odor and an acrid flavor, and by the spirit assuming a brown tint on adding a weak solution of potassium hydroxide, owing to the formation of aldehyde resin (see official test).

The pharmacists should note specially that the U. S. P. requires this Spirit to be preserved in small, well-stoppered, dark, amber-colored bottles, in a cool and dark place. The former custom of keeping it in partially filled shop bottles in the regular stock must be abandoned if the preparation is to be dispensed of official strength. This is no hardship as the stock can be filled into small bottles at the time it is made and will then be ready for dispensing.

J. G. Roberts (*A. J. P.*, 1921, xciii, 324) reports upon the stability of spirit of nitrous ether after extensive experiments with various forms of exposure and keeping. He concludes that when the product is kept as directed by the U. S. Pharmacopœia the deterioration is slight. The same conclusions were reached by Kebler, Palkin and Ewing (*J. A. Ph. A.*, 1916, pp. 514 and 1327). See also *Ph. Wb.*, 1917, liv, 1052.

Assay.—The U. S. P. and the Br. Ph. quantitative test is based on Allen's method, differing only in the relative quantities of the reagents. (See paper by Curtman, *Proc. Missouri Pharm. Assoc.*, July, 1892; also *A. J. P.*, 1898, 273.)

"Transfer about 40 cc. of Spirit of Ethyl Nitrite, which has been previously shaken with 0.5 Gm. of powdered potassium bicarbonate, to a tared, 100 cc. measuring-flask, and weigh accurately. Add sufficient alcohol to bring the volume to exactly 100 cc., and mix thoroughly. Introduce into a nitrometer, exactly 10 cc. of the alcoholic solution, follow by 10 cc. of potassium iodide T.S. and afterwards by 5 cc. of diluted sulphuric acid. When the volume of gas has become constant (within thirty to sixty minutes), note the volume of gas collected. Multiply this volume in cc. by 0.307, and divide the product by one-tenth of the weight of the Spirit of Ethyl Nitrite taken. At standard temperature and pressure, the quotient represents the percentage of ethyl nitrite in the liquid. The temperature correction is 1/273 of the total percentage just found for each degree of temperature, added if the temperature is below, subtracted if above, 25° C. The barometer correction is 1/760 of the total percentage just found for each mm., added if above, subtracted if below, 760 mm." *U. S.*

The other methods in former use were defective in consequence of the complexity of the reaction or other factors causing variation. In the *J. A. Ph. A.*, 1916, p. 1327, Englehardt and Winters suggest a new method of estimation of the ethyl nitrite, based upon Dietze's potassium chlorate method as used in the Netherland Pharmacopœia, which avoids the use of the nitrometer and barometer and gives very good results. This method, however, has some drawbacks which impel the retention of the nitrometer method for official purposes.

Uses.—Sweet spirits of niter possesses the physiological properties of the other nitrites (see *Sodii nitris*). Its inhalation produces acceleration of the pulse with the characteristic leaden purplish color of the lips, mouth and finger tips, followed by flushing of the face, giddiness, nausea, muscular debility, and violent headache. It is rarely employed, however, to produce the full physiological action of the nitrites, its chief employment being to relax the blood vessels of the skin and thereby increase the flow of sweat. It is an extremely popular diaphoretic in mild *fevers*, especially in children. Because of its action on the circulation it also at times exercises a diuretic influence.

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

SPIRITUS AMMONIÆ AROMATICUS.
U. S., Br.

AROMATIC SPIRIT OF AMMONIA Sp. Ammon. Arom.

Spiritus Ammoniæ Compositus; Spirit of Sal Volatile; Alcoolat ammoniacal aromatique, *Fr.;* Aromatischer Ammoniakgeist, *G.*

"Ammonium Carbonate, in translucent pieces, 34 Gm.; Ammonia Water, 90 cc.; Oil of Lemon, 10 cc.; Oil of Lavender, 1 cc.; Oil of Myristica, 1 cc.; Alcohol, 700 cc.; Distilled Water, a sufficient quantity, to make 1000 cc. Dissolve the ammonium carbonate in the ammonia water and 140 cc. of distilled water by gentle agitation, and allow the solution to stand for twelve hours. Dissolve the oils in the alcohol, contained in a 1000 cc. volumetric flask or cylinder, gradually add the ammonium carbonate solution, and enough distilled water to make the product measure 1000 cc. Set it aside in a cool place for twenty-four hours, occasionally agitating, and filter, using a covered funnel." *U. S.*

"Ammonium Carbonate, 100 *grammes;* Strong Solution of Ammonia, 200 *millilitres;* Oil of Nutmeg, 15 *millilitres;* Oil of Lemon, 20 *millilitres;* Alcohol (90 per cent.), 3000 *millilitres;* Distilled Water, 1500 *millilitres.* Place the Oil of Lemon, Oil of Nutmeg, and Alcohol with the Distilled Water in a retort; distil three thousand five hundred millilitres; then distil and separately collect an additional two hundred and twenty-five millilitres. Place the latter, together with the Ammonium Carbonate and the Strong Solution of Ammonia, in a bottle holding rather more than five hundred millilitres; securely cork the bottle and gently warm it in a water-bath to 60° C., shaking from time to time until all the salt has dissolved. Filter the resulting solution when cold through cotton wool, and gradually mix the filtrate with the portion first distilled." *Br.*

In both of these formulas ammonium carbonate and uncombined ammonia are used; but they differ in the relative proportion of the materials and the mode of conducting the process. The U. S. spirit is a mere solution of the ingredients in alcohol diluted with a small proportion of water, while the British contains so much of the ingredients as may rise in distillation and be condensed with the seven pints of spirit that result. The strength of the former is definite, that of the latter more or less indefinite, as a portion of the materials must be left behind. The advantage arising from distillation, however, is the avoidance of discoloration, one which is well worth considering although the spirit will always grow darker with age. The present preparation differs from that formerly official in the substitution of oil of myristica for oil of pimenta, it having been shown that oil of pimenta increased the tendency of the spirit to darken. Commercial oil of myristica frequently has a terebinthinate odor. Much care is needed to select for this preparation volatile oils that are fresh and of good quality. The translucent official ammonium carbonate, which is a mixture of bicarbonate and carbamate, does not dissolve in alcohol; the bicarbonate precipitates, and the carbonate, $NH_4HCO_3 + NH_4OH = (NH_4)_2CO_3 + H_2O$, dissolves. The object of the addition of free ammonia in the official process is to convert the insoluble bicarbonate into the carbamate, and it is directed that these shall be allowed to stand during *twelve hours* while this change is taking place. The effloresced ammonium carbonate of commerce having parted with some of its ammonia is a bicarbonate; hence, when it is used, unless more than the official proportion of the ammonia water be added, some of the ammonium salt will remain in the precipitate as ammonium bicarbonate.

The difficulty of precipitation which so many pharmacists complain of is thus explained. It is a useful precaution to permit the ammonium carbonate and ammonia water to remain in contact for twelve hours before diluting with the other ingredients; this will secure the entire conversion of the bicarbonate, and obviate the precipitation above noted. In addition to this, it is officially directed to set the mixed liquid aside, for twenty-four hours, before final filtration.

Description and Physical Properties.—"A nearly colorless liquid when freshly prepared, but gradually acquiring a yellow color. It has the taste of ammonia and an aromatic and pungent odor. Specific gravity: about 0.900 at 25° C.

"Preserve in glass-stoppered bottles, in a cool place. Alcohol content, by volume, 62 to 68 per cent." *U. S.*

"A nearly colorless transparent liquid. Odor and taste pungent and ammoniacal. Specific gravity 0.888 to 0.893. 20 millilitres require for neutralisation 25.4 millilitres of *N/1 solution of sulphuric acid,* corresponding to 2.16 grammes of ammonia, NH_3, in 100 millilitres of the Spirit. When 20 millilitres are mixed with 50 millilitres of *water* and excess of *solution of barium chloride,* the mixture heated to 70° C., the precipitate collected, washed until free from alkali, and dissolved in 20 millilitres of *N/1 solution of hydrochloric acid,* the solution thus obtained, after being boiled and cooled, requires for neutralisation not less than 7.2 or more than 8 millilitres of *N/1 solution of sodium hydroxide,* corresponding to not less than 2.35 or more than 2.51 grammes of acid ammonium carbonate and ammonium carbamate, calculated together as $N_3H_{11}C_2O_5$, in 100 millilitres of the Spirit." *Br.*

In handling this preparation on the large scale, copper vessels must never be used, as the preparation has a solvent effect upon the film of tarnish which is always present and thereby becomes contaminated, sometimes with the development of a bright green color. When this occurs, the preparation must either be thrown away or redistilled in a glass apparatus.

Uses.—Aromatic spirits of ammonia is much more widely used than the simple spirit because of its grateful taste and odor. It is used to correct *hyperacidity of the stomach* when not associated with inflammatory changes in the mucous membrane of that organ, and especially when there is *nausea* or *sick headache.* By virtue of its local irritant effect upon the mucous membrane of the stomach it will often reflexly excite the medulla and thereby relieve the feeling of *faintness.* It has, however, been enormously misapplied as a heart stimulant; as pointed out elsewhere (see *Aqua Ammoniæ*) although ammonia is a stimulant to the circulation it can act only when injected hypodermically.

Dose, thirty minims to a fluidrachm (1.8–3.75 cc.), sufficiently diluted.

Off. Prep.—Mistura Sennæ Composita, *Br.;* Tinctura Guaiaci Ammoniata, *N. F.;* Tinctura Valerianæ Ammoniata, *U. S.;* Liquor Sodæ et Menthæ, *N. F.*

SPIRITUS AMMONIÆ FŒTIDUS. Br.

FETID SPIRIT OF AMMONIA

Alcoolat ammoniacal fétide, Essence antihystérique, *Fr.;* Ammoniakalischer Stinkasantgeist, *G.*

"Asafetida, 75 *grammes;* Strong Solution of Ammonia, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Break the Asafetida into small pieces, and macerate it in a closed vessel in seven hundred and fifty millilitres of the Alcohol for twenty-four hours; distil until alcoholic vapors cease to be condensed; mix the distillate with the Strong Solution of Ammonia, and add sufficient Alcohol to produce the required volume." *Br.*

This is an alcoholic solution of the volatile oil of asafetida mixed with strong solution of ammonia, and is an energetic nervous stimulant and antacid, adapted to certain *hysterical conditions* associated with gastric weakness and acidity. It is one of the preparations formerly recognized by the British Colleges, and reinstated after having been dropped from the first British Pharmacopœia.

"A nearly colorless, transparent liquid with a strong odor of ammonia and of asafetida. Specific gravity 0.842 to 0.850. 25 millilitres require for neutralisation not less than 40 millilitres of *N/1 solution of sulphuric acid,* corresponding to not less than 2.75 grammes of ammonia, NH_3, in 100 millilitres of the Spirit." *Br.*

This preparation combines the carminative effect of asafetida with the antacid properties of ammonia. It may be used in gastric or intestinal *flatulence.*

Dose, thirty minims to a fluidrachm (1.8–3.75 cc.), to be largely diluted when administered.

SPIRITUS ANISI. U. S., Br.

SPIRIT OF ANISE Sp. Anisi

Essence of Anise; Teinture d'essence d'anis, *Fr. Cod.;* Anisgeist, *G.*

"Oil of Anise, 100 cc.; Alcohol, a sufficient quantity to make 1000 cc. Mix the oil with sufficient alcohol to make the product measure 1000 cc. Alcohol content, by volume, 80 to 87 per cent." *U. S.* "Oil of Anise, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

Dose, as a stomachic and carminative, from twenty to sixty minims (1.3–3.75 cc.), properly diluted.

SPIRITUS ARMORACIÆ COMPOSITUS. Br.

COMPOUND SPIRIT OF HORSERADISH

Esprit de Raifort composée, Alcoolat antiscorbutique, *Fr.;* Zusammengesetzter Meerrettiggeist, *G.*

"Horseradish Root, scraped, 125 *grammes;* Dried Bitter-Orange Peel, bruised, 125 *grammes;* Nutmeg, bruised, 3 *grammes;* Alcohol (90 per cent.), 625 *millilitres;* Distilled Water, 750 *millilitres.* Macerate the Horseradish Root in the Distilled Water for one hour, add the other ingredients, and distil one thousand millilitres. Specific gravity 0.917 to 0.927." *Br.*

This may be used advantageously as an addition to diuretic remedies, in *dropsy* attended with debility, especially in the case of drunkards.

Dose, from one to four fluidrachms (3.75–15 cc.).

SPIRITUS AURANTII COMPOSITUS. U. S.

COMPOUND SPIRIT OF ORANGE Sp. Aur. Co.

Teinture d'essence d'orange, Esprit d'orange composée, *Fr.;* Zusammengesetzter Orangegeist, *G.*

"Oil of Orange, 200 cc.; Oil of Lemon, 50 cc.; Oil of Coriander, 20 cc.; Oil of Anise, 5 cc.; Alcohol, a sufficient quantity to make 1000 cc. Mix the oils with sufficient alcohol to make the product measure 1000 cc.

"Preserve in dark amber-colored bottles.

"Alcohol content, by volume, 65 to 70 per cent." *U. S.*

This compound spirit has been introduced for the purpose of producing the orange flavor in making the official aromatic elixir, and in various N. F. elixirs. It will be found by physicians to be a useful and fragrant addition to prescriptions.

Off. Prep.—Elixir Aromaticum, *U. S.*

SPIRITUS CAJUPUTI. Br.

SPIRIT OF CAJUPUT

Teinture d'essence de Cajeput, Alcoolé d'essence de Cajeput, *Fr.;* Cajeputgeist, *G.*

"Oil of Cajuput, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

For an account of the medicinal properties and uses of oil of cajuput, of which this is simply an alcoholic solution, see *Oleum Cajuputi.*

Dose, from five to twenty minims (0.3–1.3 cc.), properly diluted.

SPIRITUS CAMPHORÆ. U. S., Br.

SPIRIT OF CAMPHOR Sp. Camph.

"Spirit of Camphor contains not less than 9.5 Gm. and not more than 10.5 Gm. of camphor in each 100 cc." *U. S.*

Tinctura Camphoræ, *U. S.* 1850; Tincture of Camphor; Solutum Camphoræ Alcoholicum; Alcohol Camphoratus; Teinture de camphre concentrée, *Fr. Cod.;* Esprit de Camphre, Alcool camphré, *Fr.;* Spiritus Camphoratus, *P. G.;* Kampherspiritus, *G.;* Alcohol Alcanforado, Solucion Alcoholica de Alcanfor, *Sp.*

"*Camphor,* 100 Gm.; *Alcohol,* a sufficient quantity, to make 1000 cc. Dissolve the camphor in about 800 cc. of alcohol and add enough alcohol to make the product measure 1000 cc. Filter if necessary." *U. S.*

"Camphor, 100 *grammes;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. Specific gravity, 0.845 to 0.850. *Optical rotation* at 15.5° C., not less than + 4°." *Br.*

"**Tests for Purity.**—Specific gravity from 0.824 to 0.826 at 25° C. Add 0.05 Gm. of anhydrous potassium carbonate to 5 cc. of Spirit of Camphor: the potassium carbonate does not liquefy or adhere to the bottom of the vessel (*added water*).

"**Assay.**—Fill a 200 mm. polariscope tube with the Spirit of Camphor and take the mean of four or more readings of the rotation, setting the instrument at zero each time. The temperature correction for each degree of temperature is half a minute, added if above, subtracted if below, 25° C. Evaporate 60 cc. or more of the Spirit of Camphor in a dish, on a water bath, and when the camphor begins to solidify stir it with a glass rod until dry. Then transfer the camphor to a watch glass, cover it with an inverted funnel and place the watch glass on wire gauze 10 cm. above a Bunsen burner having a flame 4 cm. high. When the camphor has all sublimed, dissolve 2.5 Gm. of the sublimate in sufficient alcohol to make exactly 25 cc., and take the mean of four or more polariscope readings in a 200 mm. tube as before. The minutes of rotation of the Spirit of Camphor, divided by the minutes of rotation of the control test, and this multiplied by 10, shows the number of Gm. of camphor in 100 cc. of the Spirit of Camphor.

"Alcohol content, by volume, 80 to 87 per cent." *U. S.*

For other methods of assay, see *Ph. Centralh.*, 1901, 472 and 1915, 579; *J. S. C. I.*, 1919, xxxviii, 923a; and *Chem. Abs.*, 1919, xiii, 55.

The camphor content of the spirit is easily obtained by the official method when a polariscope is available, but the detection of the addition of water is a more difficult task. This has been worked out by Maiden and Elliot, and the results of the method published in the *J. A. Ph. A.*, 1914, p. 91.

Spirit of camphor is an excellent preparation, much used in *diarrhea,* and in *hysteria* and other forms of *nervous excitement.* Dilution with water precipitates the camphor, but when as in many cases it is desired to combine it with aqueous preparations, by dropping it into brandy or whisky and then adding water an eligible preparation is obtained; or the spirit of camphor may be dropped upon sugar and then mixed with water.

Dose, from ten to thirty minims (0.6–1.8 cc.).

Off. Prep.—Lotio Ammoniacalis Camphorata, *N. F.;* Mistura Opii et Chloroformi Composita, *N. F.;* Mistura Opii et Rhei Composita, *N. F.;* Tinctura Opii et Gambir Composita, *N. F.*

SPIRITUS CHLOROFORMI. U. S., Br.

SPIRIT OF CHLOROFORM Sp. Chlorof.

Chloric Ether, Spirit of Chloric Ether, *Br.;* Alcoolé de Chloroforme, *Fr.;* Chloroformspiritus, *G.*

"Chloroform, 60 cc.; Alcohol, a sufficient quantity to make 1000 cc. Mix the chloroform with sufficient alcohol to make the product measure 1000 cc. Preserve in dark amber-colored bottles.

"Alcohol content, by volume, 85 to 91 per cent." *U. S.* "Chloroform, 50 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve." *Br.*

It is to be regretted that the name Chloric Ether has been retained as a synonym in the British Pharmacopœia, 1914. There would be some reason for naming a mixture of chloroform and ether by the title chloric ether, but to use the term for an alcoholic solution of chloroform must inevitably cause confusion.

Chloric ether of the older works was a solution of variable strength of chloroform in alcohol, and was used as a general anesthetic. The practice has, however, very properly been abandoned, and the spirit of chloroform is now used as an internal remedy, especially in cases of *gastro-intestinal spasm* or *pain,* in which it acts as a local agent. The official aromatic elixir is an agreeable vehicle for its administration.

Dose, from ten to sixty minims (0.6–3.75 cc.).

SPIRITUS CINNAMOMI. U. S., Br.

SPIRIT OF CINNAMON Sp. Cinnam.

Teinture d'essence de Cannelle, Esprit de Cannelle, *Fr.;* Zimmtspiritus, *G.;* Spirito di cannella, *It.*

"Oil of Cinnamon, 100 cc.; Alcohol, a sufficient quantity to make 1000 cc. Mix the oil with sufficient alcohol to make the product measure 1000 cc.

"Alcohol content, by volume, 80 to 87 per cent." *U. S.*

"Oil of Cinnamon, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

The spirit of cinnamon is an agreeable aromatic cordial.

Dose, from ten to thirty minims (0.6–1.8 cc.) in water.

SPIRITUS FRUMENTI. U. S.

WHISKY Sp. Frum.

"Whisky is an alcoholic liquid obtained by the distillation of the fermented mash of wholly or partly malted cereal grains, and containing not less than 47 per cent. and not more than 53 per cent. by volume of C_2H_5OH, at 15.56° C. It must have been stored in charred wood containers for a period of not less than four years." *U. S.*

Eau de Vie de Graines, *Fr.;* Kornbranntwein, *G.;* Orzo Stillato, *It.*

The term "whisky" is a corruption of the Gaelic "usquebaugh" or more correctly "uisgebeatha," which signifies "water of life" and is said to have been first applied to the spirit obtained from barley in the Highlands of Scotland. As at present understood and as officially defined, whisky is the distilled spirit from the mash of various grains, including maize, wheat, rye and barley. In the United States it is generally made from corn or rye. The term is occasionally extended to other forms of ardent spirit; that resulting from the distillation of cider is frequently although incorrectly designated as "apple whisky."

In the preparation of whisky, the infusion of partially germinated grain (see *Maltum*), which is known as "mash," is made to ferment by the addition of yeast. This is submitted to distillation, the resulting product being denominated "low wine." By a second distillation it becomes purer and stronger and is known as "raw spirit" or "raw whisky." When stored in wooden vessels it undergoes slow oxidation losing the disagreeable odor and taste which it is apt to have when first distilled. It is generally believed that these changes involve the conversion of the aldehydic constituents of raw spirit into acids which unite with the higher alcohols of the fusel oil (see *Amyl Alcohol*, Part II) to form esters, the latter giving the improved taste and mellowness to aged whisky. The oxidation of the aldehydic constituents may be accomplished more rapidly by percolating the whisky through wood shavings. The peculiar flavor of Scotch whisky is due to the presence of small amounts of creosote and other constituents of smoke derived from the use of kiln-dried malt which has absorbed empyreumatic products.

When freshly distilled, whisky is colorless, but when stored in charred wooden casks it acquires its characteristic color from the carmelized "wood gum" of the barrel. During storage there is an increase in acidity, a loss of amyl alcohol and apparently a slight increase in the amount of furfural.

There are volatile principles naturally existing in the grains which are carried over in the successive distillations and give their characteristic flavor to the resulting spirit. These can scarcely be considered as impurities but there are others produced during the process of fermentation which seriously contaminate the product. Among these is the mixture known as fusel oil which is offensive both to smell and to taste. Minute proportions of acetic and butyric acids are often present in whisky and valeric acid has been reported.

A spurious or imitation whisky is often made by the addition of caramel or other coloring matter to alcohol and the addition of some genuine whisky to impart a characteristic flavor. This has led to considerable argument as to the definition of whisky, a question which can not be considered as entirely settled even at the present time although the question is not now as important as it was some years ago when the sale of whisky was only regulated by licensing provisions of the laws. What is a straight whisky, what is a blended whisky and what is an imitation whisky are the three fundamental questions. There is little argument over the first and the third of these questions. It is the second one upon which there is disagreement. *Straight whisky* is whisky which has been aged in wood for a sufficient length of time to ensure the changes by which the congeners of the alcoholic distillate are altered in a manner which produces the characteristic odor and taste distinctive of whisky, coloring matter from the charred oak barrels being at the same time taken up. *Imitation whisky* is an alcoholic liquid of approximately the same proof strength as whisky and colored and flavored in imitation of the same.

Blended whisky according to the original interpretation of Dr. H. W. Wiley, then head of the Bureau of Chemistry, is a mixture of straight whiskies of different types and varying degrees of maturity. This position was reversed by the U. S. Dept. of Agriculture officials in 1907 and the reversal was upheld by a decision of President Taft who acted as arbiter in the matter. The text of President Taft's decision, given Feb. 16, 1910, is as follows: "The term 'straight whisky' is well understood in the trade and well understood by consumers. There is no reason, therefore, why those who make straight whisky may not have the brand upon their barrels of straight whisky with further descriptive terms as 'Bourbon' or 'Rye' whisky, as the composition of the grain used may justify, and they may properly add, if they choose, that it is aged in the wood. Those who make whisky of 'rectified,' 'redistilled,' or 'neutral' spirits cannot complain if, in order to prevent frauds, they are required to use a brand which shall show exactly the kind of whisky they are selling. For that reason it seems to me fair to require them to brand their product as 'whisky made from rectified spirits,' or 'whisky made from redistilled spirits,' or 'whisky made from neutral spirits,' as the case may be; and if aged in the wood, as sometimes is the case with this class of whiskies, they may add this fact. A great deal of the liquor sold is a mixture of straight whisky with whisky made from neutral spirits. Now, the question is whether this ought to be regarded as a compound or a blend. The Pure Food Law provides that 'in the case of articles labelled, branded, or tagged so as to plainly indicate that they are compounds, imitations, or blends,' the term 'blend' shall be construed to mean a mixture of like substances, not excluding harmless coloring or flavoring ingredients used for the purpose of coloring and flavoring only. It seems to me that straight whisky and whisky made from neutral spirits, each with more than 99½ per cent. ethyl alcohol and water, and with less than half of one per cent. of fusel oil, are clearly a mixture of like substances, and that while the latter may have and often does have burnt sugar or caramel to flavor and color it, such coloring and flavoring ingredients may be regarded as for flavoring and coloring only, because the use of burnt sugar to color and flavor spirits as whisky is much older than the coloring and flavoring by the tannin of the charred bark. Therefore, where straight whisky and whisky made from neutral spirits are mixed, it is proper to call them a blend of straight whisky and whisky made from neutral spirits. This is also in accord with the decision of the British Royal Commission in the case which I have cited upon a similar issue. Neutral spirits made from molasses and reduced to potable strength has sometimes been called whisky, but not for a sufficient length of time or under circumstances justifying the conclusion that it is a proper trade name. The distillate from molasses used for drinking has commonly been known as rum. The use of whisky for it is a misbranding."

The following standards were then adopted by the Joint Standards Committee of the Association of Official Agricultural Chemists, and the American Society of National Food and Dairy Officials: *New whisky* is the properly distilled spirit from the properly prepared and properly fermented mash of malted grain, or of grain the starch of which has been hydrolyzed by malt; it has an alcoholic strength corresponding to the excise laws of the various countries in which it is produced, and contains in 100 liters of proof spirit not less than 100 grammes of the various substances other than ethyl alcohol derived from the grain from which it is made, and of those produced during fermentation, the principal part of which consists of higher alcohols estimated as amylic. *Whisky* (*potable whisky*) is new whisky which has been stored in wood not less than four years without any artificial heat save that which may be imparted by warming the storehouse to the usual temperature, and contains in 100 liters of proof spirit not less than 200 grammes of the substances found in new whisky, save as they are changed or eliminated by storage, and of those produced as secondary bodies during aging; and, in addition thereto, the substances extracted from the casks in which it has been stored. It contains, when prepared for consumption as permitted by the regulations of the Bureau of Internal Revenue, not less than 45 per cent. by volume of ethyl alcohol, and, if no statement is made concerning its alcoholic strength, it contains not less than 50 per cent. of ethyl alcohol by volume, as prescribed by law. *Rye whisky* is a whisky in the manufacture of which rye, either in a malted condition or with sufficient barley or rye malt to hydrolyze the starch, is the only grain used. *Bourbon whisky* is a whisky made in Kentucky from a mash of Indian corn and rye, and barley malt, of which Indian corn forms more than 50 per cent. *Corn whisky* is whisky made from malted Indian corn or of Indian corn the starch of which has been hydrolyzed by barley malt. *Blended whisky* is a mixture of two or more whiskys. *Scotch whisky* is *whisky* made in Scotland solely from barley malt, in the drying of which peat has been used. It contains in 100 liters of proof spirit not less than 150 grammes of the various substances prescribed for whisky exclusive of those extracted from the cask. *Irish whisky* is whisky made in Ireland, and conforms in the proportions of its various ingredients to Scotch whisky, save that it may be made of the same materials as prescribed for whisky, and the malt used is not dried over peat.

Neutral spirit is a grain distillate, of a high degree of purity and known as "silent spirit" on account of the ease with which it may be used as a blending ingredient without the production of a harsh and disagreeable odor.

Description and Physical Properties.—"A light to deep amber-colored liquid, having a characteristic odor and taste, and an acid reaction.

"Specific gravity: from 0.935 to 0.923 at 25° C.

"The residue obtained by evaporating 20 cc. of Whisky in a dish on a water bath is not completely soluble in 5 cc. of distilled water. Filter the solution and add to the filtrate a drop of diluted ferric chloride T.S. (1 in 10): a greenish-black coloration is produced (*indicating storage in wood barrels*). A 25 cc. portion of Whisky, diluted with 50 cc. of distilled water, requires for neutralization not less than 1.5 cc. and not more than 5 cc. of tenth-normal sodium hydroxide, using 3 drops of phenolphthalein T.S. as indicator. Mix 100 cc. of Whisky with 15 cc. of distilled water and slowly distil 100 cc., using an efficient condenser. Neutralize 50 cc. of the distillate with tenth-normal sodium hydroxide, using 5 drops of phenolphthalein T.S. as indicator, then add exactly 20 cc. more of the tenth-normal sodium hydroxide and boil for one hour under a reflux condenser. Cool and titrate the excess of alkali with tenth-normal sulphuric acid. Run a blank test, using distilled water in place of the distillate and make any necessary correction. The volume of tenth-normal sodium hydroxide consumed is not less than 1.7 cc. and more than 7 cc. (*esters*). To 5 cc. of the distillate add 2 cc. of sodium hydroxide T.S. and 5 drops of a freshly prepared aqueous solution of sodium nitroprusside (1 in 50), then add a slight excess of acetic acid: no violet tint is produced in one minute (*acetone*). A mixture of 0.5 cc. of the distillate with 5 cc. of distilled water meets the requirements of the test for *methanol* under *Alcohol*. Acidulate 10 cc. of Whisky with 5 drops of diluted hydrochloric acid and evaporate to 5 cc. Dilute with distilled water to 10 cc. and filter if necessary. The addition of iodine T.S. or mercuric potassium iodide T.S. yields no precipitate (*alkaloids*). Dilute 10 cc. of Whisky with 2 cc. of distilled water, transfer to a test tube, and shake gently for two minutes with 15 cc. of a mixture of 100 cc. of amyl alcohol, 3 cc. of phosphoric acid, and 3 cc. of distilled water, and allow the layers to separate completely: the lower aqueous layer is colorless or very nearly so (*caramel*). Mix 5 cc. of Whisky with 5 cc. of distilled water and shake the mixture with 10 cc. of purified petroleum benzin. Transfer the separated benzin to a dish of from 70 to 80 cc. capacity, add 1 cc. of sodium hydroxide solution (1 in 10), and evaporate to dryness on a water bath. Add to the dry residue 2 cc. of sulphuric acid, rotating the acid in the dish so that the residue will be completely moistened. Heat for two minutes on a water bath, and pour the solution into a dry test tube containing from 0.03 to 0.05 Gm. of resorcinol. Heat the mixture for three minutes at 160° to 170° C., shaking at intervals to dissolve all of the resorcinol. Then pour the solution into a mixture of 70 cc. of distilled water and 30 cc. of sodium hydroxide solution (1 in 10), adding more sodium hydroxide, if necessary, to make the mixture alkaline. The liquid shows no yellowish-green fluorescence after standing twenty-four hours (*diethylphthalate*). Mix 2 cc. of an aqueous solution of phloroglucinol (1 in 100) with 5 cc. of sodium hydroxide T.S. and add 2 cc. of Whisky: no red color is produced (*formaldehyde*). Mix 20 cc. of Whisky with 20 cc. of distilled water and shake the mixture with 10 cc. of ether. Allow the mixture to stand until separation takes place, separate the ether layer, and allow it to evaporate spontaneously on a watch glass: the residue has no disagreeable or irritating odor. Evaporate 20 cc. of Whisky in a dish on a water bath and dry the residue to constant weight at 100° C.: the weight of the residue does not exceed 0.10 Gm. This residue is not sticky, it has a slightly astringent taste but is not distinctly sweet or bitter (*glycerin, sugar, etc.*). Evaporate 10 cc. of Whisky to 5 cc. and dilute with 10 cc. of distilled water, acidulate with 5 drops of hydrochloric acid, and add 10 cc. of hydrogen sulphide T.S.: no precipitate is formed before or after rendering alkaline with ammonia T.S. (*heavy metals*). Place 2 cc. of mercuric sulphate T.S. in a test tube, add 5 drops of Whisky and heat the mixture just to boiling over a small Bunsen burner and remove it from the flame: no yellow precipitate is formed (*isopropyl alcohol*). The addition of an excess of bromine T.S. to 5 cc. of Whisky, diluted with an equal volume of distilled water, produces no precipitate (*phenols*)." *U. S.*

The alcoholic strength of whisky may usually be determined by taking the specific gravity directly, and calculating the alcoholic strength from the appropriate table. This method is only applicable, however, to straight whiskies, as the caramel, prune juice and other ingredients added to imitation and blended whiskies are disturbing factors. When working with unknown samples, therefore, it is customary to distil according to the directions in the U. S. P. method for determining alcohol.

In interpreting the results of the application of the U. S. P. tests for Spiritus Frumenti, the following points may be mentioned. A specimen which contains denaturants is unquestionably spurious. A specimen which is low in acidity, very light in color with no added caramel, is either an immature whisky or a straight whisky which has been reduced with silent spirit and water. This is the type legally recognized as a blended whisky even when caramel color is present but it does not meet the Pharmacopœial definition. A specimen which is low in acidity, but which contains caramel, and leaves an excessive amount of a sticky residue upon evaporation is an imitation whisky. Alcoholic strength is no criterion of the character of whisky, whatever.

Uses.—The therapeutic value of whisky depends chiefly upon the alcohol that it contains. Its advantage as an internal medicine probably depends on the characteristic flavor which makes it more acceptable to the palate and consequently less liable to cause gastric disturbance. It may be used for nearly all the therapeutic purposes both internally and externally for which alcohol of the same concentration is employed. (See *Alcohol Dilutum.*)

SPIRITUS GLYCERYLIS NITRATIS. U. S. (Br.)

SPIRIT OF GLYCERYL TRINITRATE Sp. Glyceryl. Nit. [Spirit of Nitroglycerin]

"Spirit of Glyceryl Trinitrate is an alcoholic solution containing not less than 1 per cent. and not more than 1.1 per cent. of $C_3H_5(NO_3)_3$. *Caution—Great care must be exercised in dispensing, handling, packing, transporting, and storing this Spirit, since a dangerous explosion may result if any considerable quantity of it is spilled, and the alcohol wholly or partly lost by evaporation. If, through accident, it is spilled, a solution of potassium or sodium hydroxide must be poured over it at once to effect partial decomposition.*" *U. S.*

Liquor Trinitrini, *Br.;* Solution of Trinitrin; Liquor Nitroglycerini; Spiritus Glonoini; Spirit of Glonoin; Solution of Nitroglycerin; Liquor Glonoini; Solution of Glonoin; Nitroglyceringeist, Glycerintrinitratlösung, *G.;* Solucion Alcoholica de Trinitrina, *Sp.*

The U. S. gives no process for this, that of the Br. is as follows:

"Trinitroglycerin of commerce, 1 *gramme;* Alcohol (90 per cent.), sufficient to produce 100 *millilitres.* Dissolve." *Br.*

Description and Physical Properties.—"A clear, colorless liquid, having the odor of alcohol. *Caution must be exercised in tasting it,* since even a small quantity is liable to produce a violent headache. The same effect is produced when it is applied to the skin.

"Specific gravity: 0.814 to 0.820 at 25° C. It is neutral to litmus paper. Heat about 10 cc. of Spirit of Glyceryl Trinitrate on a water bath with 1 cc. of potassium hydroxide T.S. until the alcohol is evaporated, and then heat a portion of the residue with about 1.5 Gm. of potassium bisulphate: the pungent odor of acrolein is evolved. Dissolve the remainder of the residue in 2 cc. of distilled water acidulated with diluted sulphuric acid, add a few drops of diphenylamine T.S., and pour the solution upon 2 cc. of sulphuric acid in a test tube so as to form a separate layer: a dark blue color is produced at the zone of contact. On mixing 10 cc. of the Spirit with 11 cc. of distilled water, both previously cooled to 15° C., a clear solution results. On now adding 2 cc. more of distilled water the mixture becomes turbid at 15° C.

"**Assay.**—Transfer about 5 cc. of the Spirit, accurately weighed, to a tared dish, protect it from dust, allow it to evaporate spontaneously, and dry the residue to constant weight over sulphuric acid. The weight of the residue corresponds to not less than 1 per cent. and not more than 1.1 per cent. of the weight of Spirit taken.

"Preserve in well-stoppered bottles, in a cool, dark place, remote from fire. Alcohol content, by volume, 88 to 95 per cent." *U. S.*

"A clear colorless liquid, neutral to *litmus*. Specific gravity 0.840. A mixture of 10 millilitres with an equal volume of *water*, cooled to 15.5° C., remains clear, but the further admixture of 1 millilitre of *water* causes opacity (presence of a due amount of glyceryl trinitrate). On further diluting with *water* and setting aside the mixture, there is deposited a liquid of oily consistence, one drop of which, absorbed by paper and struck with a hammer on a hard surface, explodes. This Solution contains 1 gramme of trinitroglycerin in 100 millilitres; 110 minims contain 1 grain." *Br.*

For a method of assaying this spirit, by Chas. Rice, see *Am. Drug.*, 1895, 6; also Nagelvoort's method, *A. J. P.*, 1894, 527. F. W. Heyl and J. F. Staley reviews the various methods for the estimation of nitroglycerin and gives comparative results of the assay of a large number of preparations and tablets. (*A. J. P.*, 1914, p. 195.) On account of the importance of nitroglycerin as a therapeutic agent, we append the following:

Nitroglycerin. Trinitrine. Glonoin. Glyceryl Trinitrate. $C_3H_5(NO_3)_3$.—When glycerin is gradually added in small portions at a time to a mixture of one part of strong nitric acid and three to four parts of concentrated sulphuric acid, and at a temperature kept low by artificial refrigeration, it is converted into a bright yellow liquid, which has remarkable explosive properties. Nitroglycerin was discovered in the year 1847 by Sobrero of Turin, who called it *pyroglycerine.* It was afterwards made a subject of study by de Vrij of the Netherlands, Gladstone, and Kopp, but did not attract general attention until 1867, when Alfred Nobel, a Swedish engineer, suggested its use for explosive purposes by mixing it with inert substances like kieselguhr or infusorial earth to make the product commercially known as *dynamite.* It is an almost colorless or slightly yellow liquid of a sp. gr. of about 1.6; inodorous; of a sweet, pungent, aromatic taste; very slightly soluble in water, but readily soluble in ether, alcohol, most immiscible solvents, and oils. According to J. R. Wagner, it does not freeze above –15.5° C. when quite pure, but as it occurs in commerce it solidifies on continued exposure to a temperature of 8° C., assuming the form of long needles, which are dangerous to handle, as they explode violently when gently broken. In the form of a solution it is not explosive. In the liquid state the mere contact of flame does not inflame or explode it; but concussion, or touching it with a red-hot iron, explodes it with great violence. Detonating mixtures, or exploding gunpowder, in its near vicinity, produce the same effect. By keeping, it undergoes partial decomposition, and in confined vessels the pressure of the accumulated gases which result is sometimes so great as to cause its explosion upon the slightest concussion. Its explosive force greatly exceeds that of gunpowder. According to Nobel, one volume of the fluid yields on explosion 10,384 volumes of gas, while one volume of gunpowder yields only 800 volumes. It has, therefore, been much employed in blasting rocks, in mining, quarrying, road making, etc., and its economical advantages have kept it in extensive use, notwithstanding the danger.

Nitroglycerin is formed by the introduction of the nitro-group (NO_2) in place of the three replaceable hydrogen atoms of the glycerin formula, according to the reaction:

$$C_3H_5(OH)_3 + 3(HNO_3) = C_3H_5,(NO_3)_3 + 3(H_2O)$$

The theoretical proportions of the reacting substances would be 100 parts by weight of glycerin and over 200 parts of absolute nitric acid. On the manufacturing scale about 25 per cent. excess of nitric acid is used. The sulphuric acid exceeds the nitric acid in amount by 1½ times. Nitroglycerin, being an ester, is readily saponified and rendered harmless when brought into contact with alkali hydroxides even in the cold. The reaction is as follows: $C_3H_5(NO_3)_3 + 3KOH = C_3H_5(OH)_3 + 3KNO_3$.

A complete and well illustrated article on nitroglycerin manufacture will be found in Molinari's Industrial Organic Chemistry, p. 223.

Uses.—The effects of nitroglycerin upon the system are precisely similar to those of the nitrites (see *Sodii Nitris*). According to the observations of Wallace and Ringer (*J. A. M. A.*, 1909, lii, p. 1629), the effects of one and one-half minims of the spirits of nitroglycerin come on within two or three minutes after taking by the mouth and endure for about one-half hour. The amount of the drug required to affect the system varies extraordinarily in different individuals. Murrell (*L. L.*, 1879, i, p. 80) has reported violent effects from one or two minims of the 1 per cent. solution. On the other hand, Kolipinski (*M. News*, 1890) reports a case in which two drachms of the official solution were taken without serious symptoms (amount somewhat doubtful). It is probable that in many of these cases in which large quantities have been ingested the drug was of inferior quality. Nitroglycerin is a volatile substance and unless evaporation is guarded against its preparations lose potency. The spirit of glyceryl nitrate is used in the same class of cases as sodium nitrite, but is employed where rapidity of action is important, as in *angina pectoris, threatened apoplexy, asthma, strychnine poisoning,* and the like. It has been enormously misused as a cardiac stimulant in various forms of collapse;

it should be remembered that its effect is always to lower blood pressure and it can do no good in any form of circulatory failure. It has been highly recommended in *hemoptysis,* its action being attributable to the consentaneous dilatation of the abdominal and contraction of the pulmonary vessels.

According to Ebright (*J. A. M. A.,* 1914, lxii, p. 201), workers in dynamite factories are subject to chronic nitroglycerin poisoning. The most characteristic symptom of this intoxication is throbbing headache, at times so violent that the patient may become maniacal. The pain is made worse by lying down and is not alleviated by either acetphenetidin or morphine. After some time the workers in these factories appear to develop an immunity to the poisoning.

Dose, of the spirit, from one to two minims (0.06–0.12 cc.).

Off. Prep.—Elixir Euphorbiæ Compositum, *N. F.*

SPIRITUS JUNIPERI. Br.

SPIRIT OF JUNIPER Sp. Junip.

Teinture d'essence de Genièvre, *Fr.;* Spiritus Juniperi, *P. G.;* Wachholderspiritus, *G.*

"Oil of Juniper, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter. This Spirit is of twice the strength of the corresponding preparation of the British Pharmacopœia, 1898." *Br.* This spirit has been omitted from the U. S. X; that formerly official was half the strength of the British preparation. The compound spirit (*Spiritus Juniperi Compositus*) was formerly recognized by the U. S. Its formula was: "Oil of Juniper, *eight mils;* Oil of Caraway, *one mil;* Oil of Fennel, *one mil;* Alcohol, *fourteen hundred mils;* Water, *a sufficient quantity,* to make *two thousand mils.* Dissolve the oils in the alcohol, and gradually add enough water to make the product measure *two thousand mils.*" *U. S. IX.*

This spirit is used chiefly as an addition to diuretic infusions.

Dose, from ten to twenty minims (0.6–1.2 cc.).

SPIRITUS LAVANDULÆ. U. S., Br.

SPIRIT OF LAVENDER Sp. Lavand.

Teinture d'essence de Lavande, *Fr.;* Spiritus Lavandulæ, *P. G.;* Lavandelspiritus, *G.*

"Oil of Lavender, 50 cc.; Alcohol, a sufficient quantity to make 1000 cc. Mix the Oil with sufficient alcohol to make the product measure 1000 cc.

"Alcohol content, by volume, 85 to 92 per cent." *U. S.*

"Oil of Lavender, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

Spirit of lavender is used widely as a perfume, and as an ingredient in other preparations. The perfume usually sold under the name of *lavender water* is not a distilled spirit, but an alcoholic solution of the oil, with the addition of other odorous substances. The following is given by Brande as one of the most approved recipes for preparing it. "Take of rectified spirit five gallons, essential oil of lavender twenty ounces, essential oil of bergamot five ounces, *essence of ambergris* [made by digesting one drachm of *ambergris* and eight grains of musk in half a pint of alcohol] half an ounce. Mix." The Br. spirit is double the strength of the U. S. preparation.

It is a grateful stimulant and carminative when administered in sweetened water.

Dose, of the U. S. Spirit, from ten to thirty minims (0.6–1.8 cc.); of the Br. Spirit, five to twenty minims (0.3–1.3 cc.).

Off. Prep.—Mistura Ferri Composita, *N. F.*

SPIRITUS MENTHÆ PIPERITÆ. U. S., Br.

SPIRIT OF PEPPERMINT Sp. Menth. Pip. [Essence of Peppermint]

Teinture d'essence de Menthe, *Fr. Cod.;* Esprit de Menthe; *Fr.;* Spiritus Menthæ Piperitæ, *P. G.;* Pfefferminzspiritus, Englische Pfefferminzessenz, *G.;* Alcohol de menta piperita, *Sp.*

"Oil of Peppermint, 100 cc.; Peppermint, bruised, 10 Gm.; Alcohol, a sufficient quantity to make 1000 cc. Macerate the peppermint leaves, freed as much as possible from stems, during one hour in 500 cc. of water, and then strongly express them. Mix 800 cc. of alcohol with the oil, add the moist, macerated leaves, and allow to stand during six hours with frequent agitation. Filter and pass sufficient alcohol through the filter to make the product measure 1000 cc.

"Preserve in amber-colored bottles. Alcohol content, by volume, 79 to 85 per cent." *U. S.*

"Oil of Peppermint, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

This is one of the numerous spirits that were made by distillation, but are now made of more uniform strength and better quality by simple solution of the oil in alcohol. The American spirit is green in color, but the British is almost colorless. P. H. Utech suggests the maceration of the peppermint in water for two hours, washing and draining, before adding to the solution of the oil; water soluble matter is removed and a more permanent green color produced. He recommends the same treatment for the spearmint in making spirit of spearmint, and the U. S. P. IX adopted this plan. It has long been popularly used under the name of *essence of peppermint.* The flavoring "extract" or "essence" as it is called is a much weaker preparation and contains but 3 per cent. by volume of the oil. It must not be confused with the official spirit. (See article by E. F. Kelly, *J. A. Ph. A.,* 1919, viii, 115.) The spirit of peppermint affords a convenient method of administering a dose of the volatile oil, being of such a strength that when dropped on loaf-sugar it may be taken without inconvenience. For a discussion of the methods of assay for this preparation (see a paper by H. L. Thompson, *A. J. P.*, 1916, lxxxviii, 303.)

Dose, ten to thirty minims (0.6–1.8 cc.), given as just mentioned, or mixed with sweetened water.

SPIRITUS MENTHÆ VIRIDIS. U. S.

SPIRIT OF SPEARMINT Sp. Menth. Vir.

Tinctura Olei Menthæ Viridis, *U. S.* 1850; Essence of Spearmint; Grüne Minzessenz, *G.*

"Oil of Spearmint, 100 cc.; Spearmint, bruised, 10 Gm.; Alcohol, a sufficient quantity to make 1000 cc. Macerate the spearmint leaves, freed as much as possible from stems, during one hour in 500 cc. of water, and then strongly express them. Mix 800 cc. of alcohol with the oil, add the moist macerated leaves, and allow to stand during six hours with frequent agitation. Filter, and pass sufficient alcohol through the filter to make the product measure 1000 cc.

"Preserve in amber-colored bottles. Alcohol content, by volume, 79 to 85 per cent." *U. S.*

The remarks made on the Spirit of Peppermint are equally applicable here.

Dose, ten to thirty minims (0.6–1.8 cc.).

SPIRITUS MYRISTICÆ. Br.

SPIRIT OF NUTMEG [Essence of Nutmeg]

Teinture d'essence de Muscade, *Fr.;* Muskatspiritus, *G.*

"Oil of Nutmeg, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

It is used chiefly for its flavor. (See *Oleum Myristicæ.*)

Dose, from five to twenty minims (0.3–1.3 cc.).

SPIRITUS ROSMARINI. Br.

SPIRIT OF ROSEMARY

Spiritus Anthos; Teinture d'essence de Romarin, *Fr.;* Rosmarinspiritus, *G.;* Alcohol de romero, *Sp.*

"Oil of Rosemary, 100 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Dissolve. When not clear, shake with a little *powdered talc* and filter." *Br.*

This spirit is not official in the United States Pharmacopœia X. It is a grateful perfume, and is used chiefly as an odorous ingredient in lotions and liniments.

SPIRITUS VINI VITIS. U. S.

BRANDY Sp. Vin. Vit.

"Brandy is an alcoholic liquid obtained by the distillation of the fermented juice of sound, ripe grapes and containing not less than 48 per cent. and not more than 54 per cent. by volume of C_2H_5OH, at 15.56° C. It must have been stored in wood containers for a period of not less than four years." *U. S.*

Eau de Vie, *Fr.;* Branntwein, Schnapps, *G.;* Acquavite, *It.*

The term "brandy" has been applied generically to the ardent spirit obtained by the distillation of a fermented fruit juice. More frequently it is used in the official sense to designate grape brandy, that is, the liquor distilled from wine. This form of brandy is often known as *cognac,* from the name of a town in the Department of Charrente, France.

The process of manufacturing brandy is essentially the same as that for making whisky (see *Spiritus Frumenti*) except that it is distilled from fermented grape juice instead of the products of grains.

During the storage of the brandy the liquor undergoes analogous changes to those which take place in whisky. As brandy is not made from cereals or starchy materials, fusel oil is never present in the genuine article. As the wood containers are not charred, brandy is of a paler color than whisky and is apt to contain a larger proportion of tannic acid. Usually the color is increased by adding caramel.

An artificial or imitation brandy is sometimes made from alcohol by flavoring with *oil of cognac.* This latter is obtained by distillation from wine lees and is said to impart the characteristic brandy flavor. Such spurious liquor may be recognized by the absence of tannin and of aldehyde and an unusually high percentage of residue on evaporation due to the artificial coloring matter, and frequently by the characteristic odor of amyl acetate which is frequently used in factitious products.

Description and Physical Properties.—"A pale amber-colored liquid, having a characteristic odor and taste, and an acid reaction. Specific gravity: from 0.933 to 0.921 at 25° C.

"Evaporate 20 cc. of Brandy in a dish on a water bath, treat the residue with 5 cc. of distilled water, filter, and add to the filtrate a drop of diluted ferric chloride T.S. (1 in 10): a greenish-black coloration is produced (*indicating storage in wood barrels*). Evaporate 20 cc. of brandy in a dish in a water bath and dry the residue to constant weight at 100° C.: the weight of the residue does not exceed 0.30 Gm. A 25 cc. portion of Brandy, diluted with 50 cc. of distilled water, requires for neutralization not more than 3.8 cc. of tenth-normal sodium hydroxide, using 3 drops of phenolphthalein T.S. as indicator (*free acid*). Dilute 20 cc. of Brandy with 5 cc. of distilled water and slowly distil 20 cc. using an efficient condenser: the distillate meets the requirements of the tests for *acetone* and *methanol* under *Spiritus Frumenti.* Brandy meets the requirements of the tests for purity under *Spiritus Frumenti* beginning with the test for *alkaloids* but omitting the tests for *caramel* and for *glycerin, sugar, etc.*" *U. S.*

Uses.—It is commonly believed that brandy has a more constipating effect than whisky but there is no convincing evidence of the truth of this tradition. The medicinal virtues of the two liquors are probably essentially the same. Brandy has a somewhat more pleasing flavor to some persons and is therefore often superior in its acceptability to the stomach.

STAPHISAGRIÆ SEMINA. Br.

STAVESACRE SEEDS

"Stavesacre Seeds are the dried ripe seeds of Delphinium Staphisagria, *Linn.*" *Br.*

Staphisagria, *U. S. IX;* Staphysagriæ Semen; Semen Staphisagriæ, Staphidiagriæ or Pedicularis; Stavesacre Seeds; Staphisaigre, *Fr.;* Stephanskörner, Läusekörner, *G.;* Stafisagria, *It.*

Delphinium Staphisagria L., or stavesacre, is a handsome, annual or biennial plant, one or two feet high, with a simple, erect, downy stem, and palmate, five- or seven-lobed leaves, supported on hairy petioles. The flowers are bluish or purple, in terminal racemes, with pedicels twice as long as the flower, and bracteoles inserted at the base of the pedicel. The sepals are five in number, irregular, petal-like, the upper one being spurred at the base. The petals are four, irregular, the two upper having long spurs which are inclosed in the spur of the calyx, the two lower having short claws. The pistils form a many-seeded pod or capsule in fruit. Alike with the seeds of many other ranunculaceous plants, those of this species require planting soon after they ripen, if a good percentage of germination is to be obtained.

The plant is a native of the south of Europe. E. M. Holmes (*P. J.*, 1921, cvi, 265) calls attention to the remarkable fact that the plant in the English botanic gardens hitherto considered to be *Delphinium Staphisagria* is in reality another species, *i.e., Delphinium pictum* Willd. The author accounts for the absence of the true plant in botanic gardens partly by the fact that it is only half-hardy in Great Britain, while *D. pictum* is hardy, and partly by the reason that the illustrations in several works on medicinal plants—even in Bentley and Trimen's "Medicinal Plants"—are incorrect or unreliable. The two species are distinguished as follows: *D. Staphisagria* has very hairy stems, glandular hairs being mixed with the long spreading soft hairs; flowers that when well-developed have an ultramarine blue tint; a calyx with very short or almost obsolete spur; carpels containing only four or five seeds. *D. pictum* Willd. has shorter soft hairs, but no glandular hairs on the stems; the flowers are of a pale lilac color; the spur is as long as the calyx segments; each carpel contains ten or twelve seeds, and these are only half the size of those of *D. Staphisagria.* The true *D. Staphisagria* extends from Teneriffe around both the northern and southern coasts of the Mediterranean to Asia Minor. It is quite possible therefore, that varieties having blossoms of different tints may occur. The evidence obtainable, however, goes to show that the form of the plant from which the seed of commerce is obtained has clear blue flowers. (*Y. B. P.*, 1899, 300.) For description of other species of this genus, see *Delphinium.* The commercial supplies of this drug are imported from Leghorn, Italy.

Description and Physical Properties.—The seeds of stavesacre are officially described as "irregularly triangular or obscurely quadrangular, arched, blackish-brown when fresh, but becoming dull greyish-brown on keeping. Surface wrinkled and deeply pitted; kernel soft, whitish, oily. No marked odor; taste nauseous, bitter and acrid." *Br.* "Under the microscope, transverse sections of Staphisagria show an outer layer of nearly tabular, thick-walled, non-lignified cells, some being extended centrifugally, and forming the reticulations of the seed-coat; 2 or 3 rows of parenchyma cells with more or less irregular thin walls; a thin layer of very small, thick-walled cells with numerous, lattice-like or reticulate pores; endosperm large, composed of polygonal cells enclosing small aleurone grains and fixed oil, the latter forming in large globules on the addition of hydrated chloral T.S." *U. S. IX.*

The seeds of the field larkspur, *D. Ajacis* L., are recognized in the National Formulary (see *Delphinium*). These are readily distinguished, being about 2 mm. in length and of a black or blackish-brown color.

Constituents.—In 1819 Lassaigne and Feneulle isolated from staphisagria an alkaloid which they called delphinine. Marquis in 1877 obtained four bases, *delphinine* (crystalline), *delphinoidine* (amorphous), *delphisine* (crystalline), *staphisagrine* (amorphous). Kara-Stojanow (*In. Dis.*, Dorpat, 1890) asserted that delphinine and delphisine were identical. Keller (*A. Pharm.*, 1910, ccxlviii, 468) maintains that none of the above writers have separated delphinine in a pure state as is shown by the great variation in empirical formulæ which they give. Walz (*A. Pharm.*, 1922, cclx, p. 9) gives the formula for delphinine, $C_{34}H_{47}O_9N$.

If delphinine be rubbed up with an equal quantity of malic acid, and some drops of concentrated sulphuric acid added, there will be produced an orange-red color passing into rose, growing deeper after some hours, and finally changing from the edges to violet, and at last becoming cobalt blue. (Tattersall, *Chem. News*, 41.) It is stated that no other alkaloid and no other organic acid, except malic, affords this reaction. (*Pflanzenstoffe*, 2d ed., 1884, 617.) The total amount of alkaloids is about 1 per cent. Ahrens (*Ap. Ztg.*, 1899, 361) obtained from the residue of the seeds of *D. staphisagria*, from which delphinine, delphinoidine, delphisine and staphisagrine had been extracted, the alkaloid *staphisagroine* (*B. Chem. G.*, 1899, 1581). For Katz's process for extracting delphinine, see *Ph. Ztg.*, 1900, 735.

Uses.—The seeds were formerly used as an emetic and cathartic, but have been abandoned in consequence of their violence. A strong tincture has been employed as an embrocation in *rheumatism.* The ointment is used to destroy *lice* and the *itch-mite.* Staphisagria should never be used internally, and when it is applied externally, care should be exercised not to put it on an abraded surface, but only upon the unbroken epidermis. In some countries the seeds are used like Cocculus Indicus to intoxicate fish.

When given in poisonous doses to the lower animals, *delphinine* produces excessive salivation, followed by violent and repeated vomiting, great disturbance of respiration, failure of heart action, gradual enfeeblement of voluntary motion and of sensation, and a peculiar fibrillary spasm of the muscles of the abdomen, which is said to be characteristic of the poisoning. Elevation of temperature and glycosuria have both been noticed; death is said to occur always from failure of respiration, though the heart is greatly enfeebled and finally ceases in diastole. According to Gauthier, the period of depression of the heart and of sensibility is preceded by one of excitement. The pupils are dilated and the motor nerve finally paralyzed. (*L. M. R.*, Oct., 1887.) Turnbull, in his work *On the Medical Properties of the Ranunculaceæ,* states that pure delphinine externally acts like veratrine, but produces more redness and burning and less tingling than that substance. He has employed it in *neuralgia, rheumatism* and *paralysis.* It may be applied by friction, in the form of ointment or alcoholic solution, in proportions varying from ten to thirty grains of the alkaloid to an ounce of the vehicle, and the friction should be continued till a pungent sensation is produced.

Internally, *staphisagrine* is said to act like delphinine, except that it does not depress the heart so much or produce fibrillary contractions. Although cases of human poisonings have occurred with staphisagria, we know of none in which the result has been fatal. The symptoms are similar to those produced in the lower animals. Kobert states that the alkaloids of staphisagria all resemble aconitine in their action, but that delphinoidine has some narcotic action.

Off. Prep.—Unguentum Staphisagriæ, *Br.*

STILLINGIA. N. F.

STILLINGIA Stilling. [Queen's Root]

"Stillingia is the dried root of *Stillingia sylvatica* Linné (Fam. *Euphorbiaceæ*). Stillingia contains not more than 3 per cent. of foreign organic matter. Stillingia which has been stored for more than two years must not be used." *N. F.*

Silver Leaf, Queen's Delight, Yaw Root; Stillingie, *Fr., G.*

Stillingia sylvatica is an indigenous perennial herb with stems two or three feet high, and alternate, sessile, oblong or lanceolate-oblong, obtuse serrulate leaves, tapering at the base, and accompanied with stipules. The staminate and pistillate flowers are distinct upon the same plant. They are yellow, and arranged in the form of a spike, of which the upper part is occupied by the male, the lower by the female flowers. The staminate florets are scarcely longer than the bracteal scales. The plant grows in pine barrens from Maryland to Florida and west to Kansas and Texas, flowering in May and June. When wounded it emits a milky juice. The commercial supplies of this drug come from the southern United States.

Description and Physical Properties.—"*Unground Stillingia.*—When entire, terete, unequally tapering, rarely branched, usually in pieces, sometimes attaining a length of 40 cm. and from 0.5 to 3 cm. in diameter, externally reddish brown, longitudinally wrinkled; fracture very fibrous; internally the bark is light reddish brown, thick, spongy, finely fibrous, with numerous resin cells and easily separable from the porous, radiate wood; odor distinct; taste bitter, acrid and pungent.

"*Powdered Stillingia.*—Pinkish brown or light reddish brown; numerous starch grains from 0.005 to 0.045 mm. in diameter, mostly single, very variable in shape, and usually with a central cleft; numerous fragments, with more or less tabular secretion cells, containing a reddish brown, amorphous, resinous substance; fragments of tracheæ mostly with simple pores and associated with wood-fibers, the walls being very thin, lignified and possessing numerous, transverse, slit-like simple pores; bast-fibers long, narrow, the walls thick and slightly lignified; fragments of reddish brown cork cells; occasionally crystals of calcium oxalate in rosettes up to 0.070 in diameter." *N. F.*

The odor is slight, peculiar, and somewhat oleaginous, but in the recent root is said to be strong and acrimonious. The taste is bitterish and pungent, leaving an impression of disagreeable acrimony in the mouth and fauces. Holm gives an excellent illustrated article on the pharmacognosy of stillingia in *Merck's Rep.*, xx, p. 412.

W. Saunders has obtained from the root a volatile oil, which he found to possess the odor, taste and peculiar acrimony of the root in a high degree. He procured six and a quarter ounces from five pounds of the dried root. It had a thick consistence, and required the addition of alcohol to render it fit for manipulation. Wm. Bichy (*A. J. P.*, 1885, p. 529) found an alkaloid which he named *stillingine.* It was obtained as an amorphous powder, volatilizable on heating, forming a sulphate in fine scale-like crystals.

Uses.—In large doses stillingia is emetic and cathartic, but is rarely used for these purposes. Smaller quantities have been supposed to exercise an alterative effect upon the system and are used in *syphilitic* and *scrofulous* conditions. The drug is probably, however, without any real value.

Dose, half a drachm to a drachm (2.0–3.9 Gm.).

Off. Prep.—Fluidextractum Stillingiæ, *N. F.;* Elixir Corydalis Compositum (from Fluidextract), *N. F.;* Fluidextractum Stillingiæ Compositum, *N. F.;* Syrupus Stillingiæ Compositus, *N. F.*

STRAMONIUM. U. S. (Br.)

STRAMONIUM Stramon. [Jamestown Weed, Jimson Weed]

"Stramonium consists of the dried leaves and flowering tops of *Datura Stramonium* Linné (Fam. *Solanaceæ*). Stramonium yields not less than 0.25 per cent. of the alkaloids of Stramonium, contains not more than 3 per cent of stems over 8 mm. in diameter, and yields not more than 4 per cent. of acid-insoluble ash." *U. S.* "Stramonium Leaves are the dried leaves of Datura Stramonium, *Linn.*" *Br.*

Stramonii Folia, *Br.;* Stramonium Leaves; Herba Stramonii; Thornapple Leaves; Thorn, Devil's or Mad Apple; Apple of Peru; Stink-weed; Jamestown (Jimson) Lily; Devil's Trumpet; Derotry; Stramoine, Pomme-épineuse, Feuilles de Stramoine, *Fr.;* Folia Stramonii, *P. G.;* Stechapfelblätter, *G.;* Stramonio, *It.;* Estramonio (Hoja de), *Sp.*

The *thornapple* (*Datura Stramonium*) is an annual plant, of rank and vigorous growth, usually about three feet high, but in a rich soil attains a height of six feet or more. The root is large, whitish, and furnished with numerous rootlets. The stem is erect, round, smooth, somewhat shining, simple below, dichotomous above, with numerous spreading branches. The leaves are petiolate, five or six inches long, of an ovate-triangular form, irregularly sinuate and toothed at the edges, unequal at the base, dark green on the upper surface, and pale beneath. The flowers are large, axillary, solitary, and peduncled, having a green, tubular, pentangular, five-toothed calyx, and a white, funnel-shaped corolla with a long tube, and a wavy plaited border, terminating in five acuminate teeth. The upper portion of the calyx falls with the deciduous parts of the flower, leaving its base, which becomes reflected and remains attached to the fruit. This is a large, fleshy, ovoid, four-valved, four-locular capsule, thickly covered with sharp spines, and containing numerous flattened, reniform seeds, attached to a central placenta. It opens at the summit. The U. S. P. IX recognized the leaves of *Datura Tatula* L. as a second source of the drug but this has been dropped from the U. S. P. X. This species is indigenous to tropical America but naturalized on waste ground throughout the greater part of the Eastern United States and in the southwestern states. It differs from *D. stramonium* in having purplish stems, lavender colored flowers and capsules which are nearly equally prickly.

It is doubtful to what country *D. stramonium* originally belonged. Many European botanists have referred it to North America, while we in return trace it to the old continent. Nuttall considers it as having originated in South America or Asia, and it is probable that its native country is to be found in some part of the East. It is said to grow wild, abundantly in southern Russia, from the borders of the Black Sea eastward to Siberia. Its seeds, being viable for a long time, are taken in the earth put on shipboard for ballast from one country to another, not infrequently springing up upon the passage, and thus propagating the plant in all regions which have any commercial connection. In the United States it is usually found abundantly in the vicinity of cultivation frequenting dung heaps, the road sides and commons, and other places where a rank soil is created by the deposited refuse of towns and villages. Its flowers appear from May to July or August, according to the latitude. Where the plant grows abundantly, its vicinity may be detected by the rank odor which it diffuses to some distance around. Notwithstanding the abundance of the plant, it is being cultivated in order to obtain a drug which shall be of uniform quality. The Bureau of Plant Industry, U. S. Department of Agriculture, has conducted experiments on a large scale. Several hundred pounds of leaf were grown, cured by artificial heat in a tobacco barn, and marketed at a price in advance of the highest quoted figure. Mitlacher has reported his observations on the cultivation of stramonium in *Zeit. Oest. Apoth.*, i, p. 391. Miller has conducted comparative experiments on *D. stramonium* and *D. Tatula.* (*A. J. P.*, lxxiv, p. 446.)

All parts of it are active. The leaves, seeds, and root were formerly recognized by the U. S. P., the present U. S. P. recognizes both the leaves and the tops. These may be gathered at any time from the appearance of the flowers till the autumnal frost. In this country the plant is generally known by the name of *Jamestown* (*vulgo, Jimson*) *weed,* derived probably from its having been first observed in the neighborhood of that old settlement in Virginia. In India *Datura alba, D. ferox,* and *D. fatuosa* are employed as poisons. The last has been admitted to the Br. (See *Daturæ Semina.*) Under the names of *Man t'o lo fa, Wan t'o lo hua,* and *Nau yeung fa,* the Chinese use as a medicine the flowers of the *Datura alba;* according to Frank Browne, they contain 0.485 per cent. of hyoscine, free from other alkaloids. *El Bethene,* a Datura of the Sahara Desert, is capable of causing delirium, coma, and death, and it is probable that all the species of the genus are poisonous. A. R. L. Dohme (*Proc. A. Ph. A.*, 1894, 231) examined stramonium to determine the value in alkaloid of the various parts of the plant; he found that in general, the fresh parts yielded more than the dried parts; the stems contained the most alkaloid, the seeds next, then the leaves, and the roots the least of all.

The drug of commerce is collected for the most part from wild plants. It is best gathered while the plants are in flower, in summer. The supplies used in the United States have been obtained partly from native plants and to a large extent from plants growing in Europe. North Carolina, Germany, Holland, England and Italy have furnished the bulk of the supply used in this country.

The *fresh leaves* when bruised emit a fetid narcotic odor, which they lose upon drying. Their taste is bitter and nauseous. The leaves, if carefully dried, retain their bitter taste.

Description and Physical Properties.—"*Unground Stramonium*—More or less matted, wrinkled and crushed; leaves petiolate, ovate; apex acuminate, base unequal; margin sinuate, toothed or angled, the teeth few, acute and with rounded sinuses; the lamina usually shows small, circular perforations, surrounded by cork or sometimes filled with cork, surfaces usually sparsely hairy, the hairs mostly upon the veins; upper surface dark green, lower surface light green. Stems often flattened, longitudinally wrinkled, occasionally with one or more deep furrows: light greenish-brown to purplish-brown. Odor distinct, heavy and narcotic; taste unpleasant and nauseous.

"*Structure.*—Upper epidermis of thin-walled cells, with few stomata and hairs; palisade, 1-rowed, and resting upon a single row of small parenchyma cells extending through the middle of the blade, nearly every cell of the layer containing a rosette aggregate of calcium oxalate; spongy parenchyma loosely arranged; lower epidermis similar to the upper but more uneven and with more stomata, the latter slightly elevated and with guard cells nearly circular in outline and distinctly beaked. At the midrib and larger veins, epidermal walls thickened; a characteristic ridge of collenchyma just beneath the upper epidermis, large, rounded parenchyma cells with intercellular spaces; a bicollateral radial vascular structure with narrow, medullary rays.

"*Powdered Stramonium.*—Bright green to brownish-green; epidermal cells with wavy radial walls; stomata elliptical, about 0.025 mm. in length, usually with 3 neighboring cells, one smaller than the others; calcium oxalate in rosette aggregates, from 0.010 to 0.025 mm. in diameter, or in rodlike crystals, or in sphenoidal microcrystals; non-glandular hairs few, 2- to 6-celled, attaining a length of about 0.5 mm., the basal cell about 0.04 mm. in width, some of the cells more or less collapsed, the outer walls with numerous slight centrifugal projections; glandular hairs few, with 1- to 2-celled, usually curved stalks and 2- to 4-celled glandular heads; tracheæ annular or spiral. Stem fragments with annular or spiral tracheæ or tracheæ with simple or bordered pores associated with wood parenchyma or wood fibers; or fragments with long narrow unequally thickened collenchymatous cells associated with parenchyma cells, some of the latter containing sphenoidal microcrystals; bast fibers absent.

"**Assay.**—Proceed by Type Process B, using 10 Gm. of Stramonium in fine powder, ether-chloroform mixture for percolating the drug, and chloroform as the immiscible solvent for extracting the alkaloids from the aqueous liquid. Determine the alkaloids volumetrically. Each cc. of tenth-normal sulphuric acid corresponds to 0.02893 Gm. of the alkaloids of Stramonium (Proximate Assays).

"Ovate, petiolate, usually from ten to fifteen centimeters long, often unequal at the base; margin sinuate-dentate, apex acuminate. Upper surface dark greyish-green; under surface paler, and minutely wrinkled. Walls of the epidermal cells sinuous; stomata on both surfaces; on the lower surface, especially of young leaves, curved multicellular hairs with thin, warty walls, and also glandular hairs with unicellular or multicellular stalks; in the mesophyll numerous cluster-crystals of calcium oxalate. Characteristic odor; taste bitter, unpleasant. Ash not more than 18 per cent." *Br.*

J. S. Ward has found commercial stramonium leaves freely adulterated with those of *Carthamus helenioides* and *Xanthium Strumarium.* (*P. J.*, lxvi, 326.) E. M. Holmes states that the leaves of *Xanthium macrocarpum* were extensively substituted for European stramonium leaves from Spain in 1918 (*C. D.*, 1920, xcii, 908). The most common adulterants of American stramonium have been the leaves of *Xanthium strumarium* and excess stems. The former may be detected by their absence of rosette crystals and presence of rod-shaped crystals of calcium oxalate and especially by their short, non-glandular hairs, each exhibiting a broad basal cell and a pointed, frequently bent terminal cell. For a paper on the structure of the leaves of *D. stramonium, Atropa Belladonna,* and *Hyoscyamus niger* by Schlotterbeck and van Zwaluwenburg, see *Proc. A. Ph. A.*, 1897, 202. Holm has published an illustrated article on the morphology of stramonium (*M. R.*, xxii, p. 162). Rosenthaler has subjected the leaves of stramonium to pyroanalysis and obtained a distinctive and characteristic sublimate. (*B. P. G.*, xxi, p. 530.)

The seeds are small, kidney-shaped, pitted and wrinkled, flattened on the sides, of a dark-brown almost black color, inodorous unless bruised, and of the bitter, nauseous taste of the leaves, with some degree of acrimony. The testa is dull brownish-black, hard, and encloses a cylindrical curved embryo, which is embedded in a whitish oily albumen. They are much more energetic in their action on the system than are the leaves.

Constituents.—Geiger and Hesse in 1833 succeeded in isolating an alkaloid, to which the name *daturine* was given and which Trommsdorff has repeatedly procured by their process.

As was first shown by Von Planta in 1852, and since confirmed by many authorities, daturine is identical with hyoscyamine (see *Belladonna*). Ladenburg described two forms of the alkaloid which he called *heavy* and *light daturine,* but the former was probably a racemized hyoscyamine (atropine) formed during the process of isolation. There is also present traces of scopolamine but not in large enough quantity to influence the physiological activity.

H. C. Brill has studied *Datura alba* for alkaloidal content and effect of drying. (*Philippine Jour. Sci.* through *Chem. Abs.*, 1918, xii, 738.) Geo. P. Koch (*A. J. P.*, 1919, xci, 11) has done considerable research in the relative alkaloidal content of the stem and of the leaves of stramonium. He states that the whole plant, with or without the root, can be used without fear of the total alkaloidal content falling below the present U. S. P. standard.

Gérard (see *J. P. C.*, 1892, 8) studied *daturic acid* obtained from stramonium seed. D. Holde has, by means of benzene, extracted from stramonium seed 16.7 per cent. of a fixed oil. (*P. J.*, lxx, p. 90.) This has been examined by J. M. Baird and F. E. Sleeper, see *Proc. A. Ph. A.*, 1903, 324.

Uses.—Stramonium is so similar to belladonna in the symptoms produced by it in small or large doses, in its toxicity and its general physiological and therapeutic action, that the two drugs are practically identical. Furthermore, they are about the same strength in activity, so the preparations may be used in similar doses. Stramonium has been employed in all the conditions for which belladonna is more commonly used, but has acquired special repute in the treatment of *asthma,* this probably being due to the fact that the practice of smoking *Datura ferox* in that disease was introduced into Great Britain from the East Indies by General Gent, and that afterwards the English species was substituted for that employed in Hindostan. Formerly the roots were chiefly used, but at present the dried leaves and tops are exclusively employed. The beneficial effect is doubtless due to the presence of atropine which paralyzes the endings of the pulmonary branch of the vagus, thus relieving the bronchial spasm, for Gunther (*W. K. W.*, 1911, p. 748) has shown that the smoke from a stramonium cigarette containing 1.25 Gm. of stramonium leaves contains as much as 0.5 Mgm. of atropine. The leaves may be made up into cigarettes or smoked in a pipe, either with or without a mixture of tobacco; more commonly, however, the coarsely ground leaves are mixed with equal parts of potassium nitrate, in order to increase combustion, and burned in a saucer.

The seeds are more powerful than the leaves. The seeds were once officially recognized but the presence of a large amount of fixed oil made it difficult to extract them or to make stable preparations from them and the leaves have taken their place. They may be given in the dose of one-half to one grain (0.032–0.065 Gm.) twice a day; an extract made by evaporating the decoction, in one-quarter or one-half the quantity. The inspissated juice of the fresh leaves was formerly very commonly prescribed; but the alcoholic extract is now almost exclusively used when a solid form is desired. (See *Extractum Stramonii.*)

Dose, of the leaves, one to three grains (0.065–0.2 Gm.).

Off. Prep.—Extractum Stramonii (Pilular and Powdered), *U. S.;* Tinctura Stramonii, *U. S., Br.;* Fluidextractum Stramonii, *N. F.*

STRONTII BROMIDUM. Br.

STRONTIUM BROMIDE Stront. Brom.

"Strontium Bromide may be obtained by neutralising dilute hydrobromic acid with strontium carbonate, evaporating and crystallising. It contains not less than 97 per cent. of pure strontium bromide, $SrBr_2,6H_2O$." *Br.*

Strontium Bromatum, *Fr. Cod.;* Bromure de Strontium, *Fr.;* Strontiumbromid, *G.;* Bromuro Estroncico, *Sp.*

This salt has been dropped from the U. S. P.

Properties.—Strontium Bromide occurs as "White acicular crystals, deliquescent. Taste saline, slightly bitter. Soluble in less than 1 part of *water,* and in *alcohol* (90 per cent.). Yields the *reactions* characteristic of bromides; an aqueous solution slowly deposits a crystalline precipitate on the addition of *solution of calcium sulphate.* A solution of 1 gramme in *water,* to which 5 millilitres of *solution of sodium acetate* and 3 millilitres of *acetic acid* have been added, does not become cloudy on the addition of 1 millilitre of *solution of potassium chromate* (absence of barium). 1 gramme dissolved in *water* requires for complete precipitation not less than 54.6 or more than 57 millilitres of *N/10 solution of silver nitrate.* 0.5 gramme moistened with *sulphuric acid* and gently ignited leaves a white residue weighing not less than 0.250 gramme. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million." *Br.*

The U. S. IX gave the following requirements: "The salt deliquesces in moist air but effloresces in very dry air. One Gm. of Strontium Bromide dissolves in 0.35 mil of water at 25° C.; soluble in alcohol; insoluble in ether. Its aqueous solution (1 in 20) is neutral to litmus. When quickly heated, the crystals at first melt, and at above 180° C. lose all of their water of crystallization. To a non-luminous flame the salt communicates a crimson color. Silver nitrate T.S. added to an aqueous solution of the salt (1 in 10) produces a yellowish white precipitate, insoluble in nitric acid or in a moderate excess of ammonia water. With calcium sulphate T.S. an aqueous solution of the salt (1 in 20) slowly forms a white precipitate of strontium sulphate, insoluble in dilute acids; the precipitation occurs more quickly with diluted sulphuric acid or a readily soluble sulphate. Add a few drops of ferric chloride T.S. and 1 mil of chloroform to 10 mils of an aqueous solution of the salt (1 in 20) and shake the mixture; the chloroform does not acquire a violet tint (*iodine*). Drop 1 mil of diluted sulphuric acid upon about 1 Gm. of the powdered salt; no yellow color appears at once (*bromate*). Dissolve 1 Gm. of Strontium Bromide and 1 Gm. of sodium acetate in 5 mils of distilled water, and render the solution slightly acid by the addition of from 3 to 5 drops (or a sufficient quantity) of diluted acetic acid. The solution, upon the addition of 5 drops of potassium dichromate T.S. and agitation, does not become cloudy within three minutes (*barium*). An aqueous solution of the salt does not respond to the Test for heavy metals." *U. S. IX.*

The U. S. IX also required that when assayed by the method for bromides it should show not less than 98 per cent. of $SrBr_2 + 6H_2O$.

"Each mil of tenth-normal silver nitrate V.S. used corresponds to 0.017778 Gm. of $SrBr_2 + 6H_2O$. Each gramme of Strontium Bromide corresponds to not less than 55.1 mils nor more than 56.6 mils of tenth-normal silver nitrate V.S." *U. S. IX.*

For further tests, see *Proc. A. Ph. A.*, 1897, 608.

Strontium bromide shows incompatibilities not shared by the other alkali bromides, from the fact that carbonates, citrates and sulphates form precipitates with strontium.

Uses.—Strontium bromide has been strongly commended as a substitute for potassium bromide in the treatment of *epilepsy* and allied conditions. It depends for its action on the nervous system upon the presence of bromine in it, and appears to act upon the nervous centers in much the same manner as does the corresponding salt of potassium. Its influence upon the general nutrition is much more favorable than is that of the potassium salt, and it is much less apt to produce the disagreeable effects of bromism. Moreover, it is less irritating to the gastro-intestinal mucous membranes, on which, indeed, it often seems to exert a beneficial influence. For these reasons many cases of epilepsy tolerate it much better than they do other bromides. In the experience of H. C. Wood, however, it seemed to be in its anticonvulsive influence among the least powerful and certain of its class. Possibly this result has been due to Wood not having employed it in sufficient dose, he never having administered more than two drachms a day, while the French observers affirm that it may be given with great advantage in the daily dose of three drachms. Strontium bromide is further stated by Sée to have an extraordinary influence in the reduction of the excretion of sugar in *diabetes,* and to be a valuable remedy in the treatment of *gastric dilatation* and *catarrh.*

Dose, fifteen to thirty grains (1–2 Gm.).

STRONTII SALICYLAS. U. S.

STRONTIUM SALICYLATE Stront. Salicyl.

"Strontium Salicylate, when dried to constant weight over sulphuric acid, contains not less than 99 per cent. of $Sr(C_7H_5O_3)_2.2H_2O$." *U. S.*

Strontium Salicylicum; Salicylate de Strontium, *Fr.;* Salicylsaures Strontium, Strontium Salicylat, *G.*

This salt may be obtained by the following process: Add 10 parts of salicylic acid to 100 parts of water, to the mixture add 5.3 parts of strontium carbonate; when the reaction is completed filter, partially evaporate and allow to crystallize.

Description and Physical Properties.—"A white, odorless, crystalline powder, having a somewhat sweet, saline taste. One Gm. of Strontium Salicylate is soluble in 19 cc. of water and in 61 cc. of alcohol, at 25° C. One Gm. is soluble in 3.7 cc. of boiling water and in 14 cc. of boiling alcohol.

"When heated, the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaving a residue of strontium carbonate and carbon. An aqueous solution of the salt (1 in 20) responds to the reactions for strontium, and for salicylates.

"An aqueous solution of the salt (1 in 30) is colorless. Add 1 cc. of diluted sulphuric acid to 10 cc. of an aqueous solution of Strontium Salicylate (1 in 50), and filter: the filtrate meets the requirements of the test for *heavy metals.* Agitate 2 Gm. of Strontium Salicylate with 10 cc. of diluted acetic acid, heat the mixture, cool, and filter: the filtrate, upon the addition of 5 drops of potassium dichromate T.S., does not become cloudy within three minutes (*barium*).

"**Assay.**—Place about 2 Gm. of Strontium Salicylate, previously dried to constant weight over sulphuric acid and accurately weighed, in a tared platinum crucible, and thoroughly carbonize it at a temperature not exceeding red heat. Dissolve the residue in 30 cc. of half-normal hydrochloric acid, and submit it to residual titration with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of half-normal hydrochloric acid corresponds to 0.09945 Gm. of $Sr(C_7H_5O_3)_2.2H_2O$.

"Preserve in well-closed containers, protected from heat and light." *U. S.*

Uses.—Strontium salicylate when taken internally is slowly decomposed in the alimentary canal with the liberation of salicylic acid, which acid, or its educts, can be detected in the urine shortly after administration. As a salicylate, the strontium salt is of especial value in subacute *rheumatic* affections, acting more slowly and persistently than most of the other allied salts. By some it is believed to have less tendency to disturb the digestion but Blankenhorn (*J. A. M. A.*, 1916, lvi, p. 331), from comparative studies in twenty-three cases of various diseases, has come to the conclusion that the toxic dose of strontium is the same as that of sodium salicylate, and that the strontium salt has no advantage in any way. It may be administered in capsule or in solution.

Dose, five to thirty grains (0.32–2.0 Gm.).

STROPHANTHINUM. U. S.

STROPHANTHIN Strophanthin.

"A glucoside or a mixture of glucosides obtained from *Strophanthus Kombe* Oliver (Fam. *Apocynaceæ*)." *U. S.*

Strophantine, *Fr. Cod.;* Strophanthin, *G.*

Preparation.—*Strophanthin* may be prepared by Fraser's process of depriving the ground seeds of fatty oil by percolation with petroleum benzin, making a tincture from the marc with 70 per cent. alcohol, distilling, evaporating and treating the extract with water; this solution is then filtered and the filtrate precipitated with tannic acid; the precipitate is washed, mixed with litharge, dried and exhausted with alcohol; by adding ether to the alcoholic liquid, strophanthin is precipitated. For an improved method, see Rowe, *J. A. Ph. A.*, 1916, v, 1183.

Description and Physical Properties.—"A white or yellowish powder containing varying amounts of water, which it does not lose entirely without decomposition. It is stable in the air. *Caution—Strophanthin is extremely poisonous.* Strophanthin is soluble in water and in diluted alcohol, but less soluble in dehydrated alcohol. It is nearly insoluble in chloroform, ether, and benzene.

"Solutions of Strophanthin are neutral to litmus paper, and are dextrorotatory. Sulphuric acid added to Strophanthin produces an emerald-green color, changing to brown. Add a trace of ferric chloride T.S. and a few cc. of sulphuric acid to an aqueous solution of Strophanthin (1 in 50): a red precipitate is produced, which turns dark green after one or two hours. A solution of 0.1 Gm. of Strophanthin in 15 cc. of distilled water, when mixed with 5 cc. of hot alkaline cupric tartrate solution, produces no precipitate. On heating an aqueous solution to 70° C. with a small amount of diluted hydrochloric acid, the Strophanthin is hydrolyzed into strophanthidin, which precipitates, and a sugar, capable of reducing alkaline cupric tartrate solution, which remains in solution. The ash from 0.1 Gm. is negligible.

"Preserve in well-closed containers, protected from light." *U. S.*

For further details of the various kinds of strophanthin and their properties, see *Strophanthus* and *Acocanthera.* Strophanthin is very susceptible to alkalies and both Levy and Cullen (*J. Ex. M.*, 1920, xxxi, 267) and Pomeroy and Heyl (*A. J. P.*, 1922, xciv, 479) have shown that ampules of strophanthin solution deteriorate very rapidly because of the alkali dissolved from the glass.

Uses.—Strophanthin fully represents the therapeutic properties of strophanthus. While occasionally used by the mouth it is usually employed where it is desirable to administer the drug by injection. On account of its intense local irritant effect the hypodermic injection is not to be recommended; the drug may, however, be thrown into the muscle substance or better, directly into a vein. In cases of severe *circulatory failure,* such as that seen in *pneumonia* and other infectious diseases, in *collapse* from *ether anesthesia,* and in *uremia,* striking results are often obtained by the intravenous injection of strophanthin. Bailey (*J. P. Ex. T.,* 1909, i, p. 349) finds the treatment of the utmost value as an emergency measure in broken compensation of *heart disease,* but not suitable for continuous use.

The confusion concerning the identity of the various strophanthins, as well as the extraordinary difference in their activity according to the channel of administration, has given rise to great diversity of statement as to the proper dosage of these glucosides. A long summary of the literature on this subject is given in *Merck's Report* for 1912, as a result of which the conclusion is reached that when given intravenously G-strophanthin is nearly twice as strong as the K-strophanthin (the official), but that when exhibited by the mouth G-strophanthin is very much weaker than the official. The conclusions reached from this article are that the maximum *daily* dose of these glucosides should not exceed for G-strophanthin, intravenously, one sixty-fourth of a grain (0.001 Gm.), by mouth, one-half grain (0.032 Gm.). Of the K-strophanthin, intravenously, one-fortieth grain (0.0016 Gm.), by mouth, one-twentieth of a grain (0.003.).

For a discussion of the various strophanthins, see *Strophanthus.*

Dose, one two-hundredth of a grain (0.0003 Gm.).
